1 INTRODUCTION

1.1 PROJECT OVERVIEW

Crosswind, a Shell and Eneco joint venture, was awarded the tender to develop the offshore Hollandse Kust Noord (HKN) wind farm, located 18.5km off the coast of Netherlands near the town of Egmond aan Zee. The consortium plans to have HKN operational in 2023 with an installed capacity of 759MW generating at least 3.3TWh per year. This is sufficient renewable power to supply more than 1 million Dutch households with green electricity.

Offshore wind farms produce intermittent electricity and balancing these dips and peaks and integrating this electricity into the national energy system requires new technologies. For this reason, the offshore wind farm will include several new technologies that could be implemented at full-scale in the future. The new technologies being explored include a floating solar park, a short-duration battery storage as well as long-term storage via green hydrogen produced by water electrolysis and subsequently consumed in a fuel cell. The combination of these individual measures, herein referred to as the Base Load Power Hub (BLPH) will ensure a continuous power supply regardless of the wind situation.

1.1.1 Project Location

The Hollandse Kust Noord (HKN) wind farm is located 18.5km off the coast of the Netherlands near the town of Egmond aan Zee.

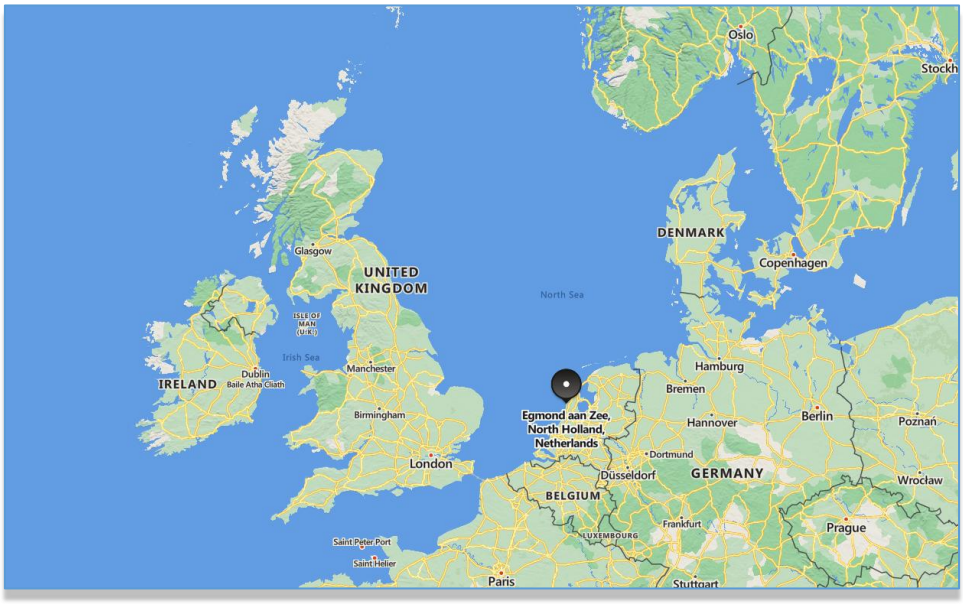

Figure 1 - HOLLANDSE KUST NOORD WIND PARK Location Map

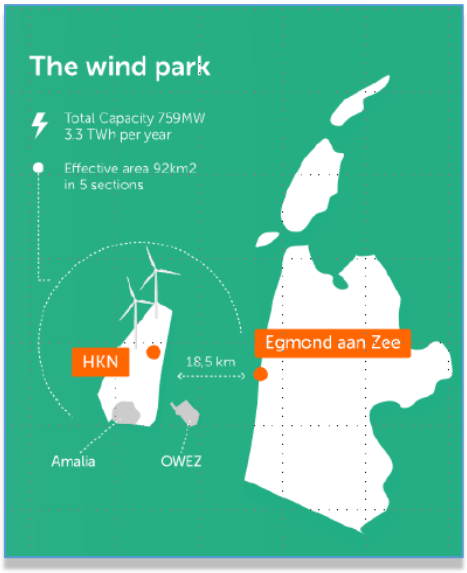

Figure 2 - Wind Park Details

The wind farm will consist of No. 69 x 11.5MW wind turbine generators each to be installed on a dedicated monopile structure. A 70th monopile located on coordinates E 590719.1, N 5841602.3 is reserved for installing the platform accommodating the BLPH. The monopile structure was designed and installed by Van Oord Offshore Wind (VooW) and therefore not part of the BLPH scope.

1.1.2 Project Concept

All components included in the BLPH will be integrated onshore on a topsides and installed in an offshore location within the boundaries of the HKN wind farm. At its simplest, the BLPH will store energy during periods of high electricity generation from renewable sources (a wind turbine generator and the floating solar PV farm) and release it during periods of low generation. In practice. It is expected that the energy stored will supplement generation from renewable sources to ensure that at least 1.0MW of power is exported to the electrical grid regardless of wind/solar availability.

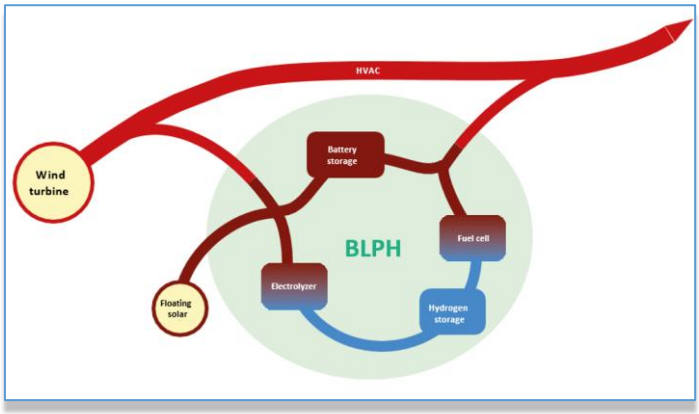

Figure 3 – BLPH Concept

Electricity in the BLPH will be stored in the form of electrons in a battery energy storage system (BESS) as well as converted into green hydrogen via water electrolysis. When the power output from the connecting wind turbine drops to below 1 MWe, the BLPH will return its stored energy to supplement the remaining power output. This will be by discharging the BESS, while stored hydrogen will be converted back into electricity using a fuel cell to extend the discharge duration.

The purpose of the BLPH is to function as a testbed for the integration of energy storage technologies with renewable generation. It is expected that equipment installed on the BLPH will operate as Normally Unmanned Installation for at least two (2) years with no or minimal maintenance and it will have its own independent control room with the ability to communicate with Crosswind's control room.

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

2 DOCUMENT SCOPE

The purpose of this document is to provide essential Instructions for Operation and Maintenance (IOM) of Yokogawa ProSafe-RS based Safety Instrumented System (SIS) and Fire & Gas System (FGS) for BLPH of HOLLANDSE KUST NOORD WIND PARK Project.

The following subjects are covered under this document:

- Instructions for operations
- Instructions for maintenance
- Instructions for proof testing
- Instructions for troubleshooting

Note that this document is not meant to supplant the actual Operations and Maintenance Procedure of the facility. It serves only as a guideline to highlight the salient points to be considered in the development of the Operations and Maintenance Procedure which falls under the authority of the Employer

2.2 ORDER OF PRECEDENCE

The approved MAC Document Deliverables developed based on the various requirements in the order of priority listed below, this shall be the reference document for all further engineering, manufacturing, FAT and SAT:

1. European directives and supporting standards
2. Dutch legislation
3. End User Technical Standards
4. Referenced Dutch standards
5. Referenced European and International standards
6. Engineering Contractor Standards
7. Project specifications.

If lower-level requirement is more stringent than upper one in the above documents, a request shall be raised to OWNER for written decision before proceeding with the Design, Manufacture or Construction.

2.3 DEFINITIONS AND ABBREVIATIONS

PROJECT:	HOLLANDSE KUST NOORD WIND PARK PROJECT
CONTRACTOR (CTR):	ROSETTI MARINO S.p.A.
COMPANY or Client (CPY):	CROSSWIND
VENDOR	YOKOGAWA ITALIA S.R.L.

OPC	Open Platform Communications
OWS	Operator Workstation
PAGA	Public Address and General Alarm
P&ID	Piping and Instrument Diagram
PACO	Process, Automation, Control and Optimisation (PACO) is the term used to describe all functionality required for the monitoring and controlling of all process, safety and fire and gas systems selected for the project.
PCN	Process Control Network
PROJECT	HOLLANDSE KUST NOORD WIND PARK Project
PURCHASER	The organisation placed a purchase order for the supply of equipment or services for the Project. The Purchaser could be the Company or the Contractor or some other party appointed by the COMPANY or Contractor.
RVO	Rijksdienst voor ondernemend Nederland – The Netherlands Enterprise Agency

SCADA	Supervisory Control and Data Acquisition
SGSI	Shell Global Solutions International
SHALL	An absolute requirement.
SHOULD	This word indicates a recommendation that whilst preferred may not be implemented provided some equivalent is proposed and agreed by COMPANY. The full implications must be understood and carefully weighed before choosing a different course.
SIF	Safety Instrumented Function
SIL	Safety Instrumented Level
SIS	Safety Instrumented System
SNU	Safety Node Unit
TB	Terminal Board
TQ	Technical Query
UHF	Ultra-High Frequency
UPS	Uninterruptible Power Supply
VENDOR	Manufacturer/Supplier of equipment and services to perform the duties specified by the Purchaser.
VLAN	Virtual Local Area Network
VNET	Virtual Network
WAN	Wide Area Network

Table 4 – Abbreviations

3 GENERAL INSTRUCTIONS

This section describes the general instructions for operation and maintenance of the Safety Instrument system (SIS/F&G). supplied for the HOLLANDSE KUST NOORD WIND PART Project.

- "Operations" involve guidelines for the user to evolve procedures for normal operations of the plant and systems. This includes Trip Reset, MOS, Start-up bypass, Emergency operation, Security, Forcing and Monitoring. Refer Sec.5 of this document for more information.
- The "Maintenance" activities can be classified as Preventive Maintenance and Corrective Maintenance.
  - Within Preventive Maintenance, one can distinguish the actions that can be done without disturbing the process (without restrictions), so called "First line Maintenance" and maintenance that will certainly disturb the process or bear a great risk to do so, called "Shutdown Maintenance". Refer Sec.6 of this document for more information.
  - Corrective Maintenance implies the replacement of the defective part, which failed and/or caused a nuisance trip. Due to the unpredictable nature of this type of maintenance this document does not cover this in great depth, but to aid with corrective maintenance a section Troubleshooting has been introduced.
- It is the responsibility of the End-User to ensure that adequate Proof testing is duly carried out throughout the lifetime of the system / facility as per the Proof test interval stipulated in the SIL calculation (if applicable). Yokogawa can assist with proof testing procedures with the end user. Physical installation of equipment in testing shall be by the end user. Refer Sec.7 of this document for more information.
- It is the responsibility of the End-User to ensure that the plant Operations and Maintenance Procedure is kept up to date to reflect the actual status of the Safety System for all "Modifications" implemented at any given time.

3.1 SYSTEMS INVOLVED

System comprises of the following equipment:

- ProSafe-RS System cabinet(s)
- Associated FIO cabinets
- Safety Engineering Workstation (EWS)
- Sequence of Event Viewer

3.2 PREREQUISITES

- All maintenance activities for the Yokogawa safety system must be in line with the regulations of IEC-61508.

- It is to be noted that the responsibility to set up the necessary procedures for operation and maintenance rests with the end user.
- The personnel responsible for the operation and maintenance activities must be competent with the system and project documentation.
- It is the responsibility of the maintenance personnel to refer to the appropriate sections in the manual and to read and understand the requirements before performing the actual maintenance activities.
- During maintenance, put up wrist strap for SIS (Electrostatic Discharge) measures (If applicable).
- There should be a periodic safety check for the system alarms, SOE messages and CPU modes (running or waiting).

3.3 PERSONAL COMPETENCY

As per requirements of IEC-61508, all personnel involved in safety life cycle activities must be competent including product training. Competency must be evaluated and documented before a person is involved in a Safety Lifecycle task. Competency records must be maintained for as long as individual remains involved in a Safety Lifecycle task.

4 SYSTEM POWER-UP

The power supplies that must be available for the system are:

System power supplies:

- SIS : 230 VAC UPS (AC UPS PAS, Line A and Line B) with autonomy of 30 min
- F&G : 230 VAC UPS (AC UPS F&G, Line A and Line B) with autonomy of Full Operation: 8 Hour

Utility power supply:

- One 230 VAC 50Hz

The utility power supply will be used to feed the following equipment per cabinet

- Cabinet fans
- Utility sockets
- Cabinet lighting

The starting point for system power up is:

- All power cables connected.
- All field cables connected (If available during the system start-up).
- All grounding cables connected.
- All interface cables to other systems connected (If available during the system start-up).
- All main switches and circuit breakers switched OFF.

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

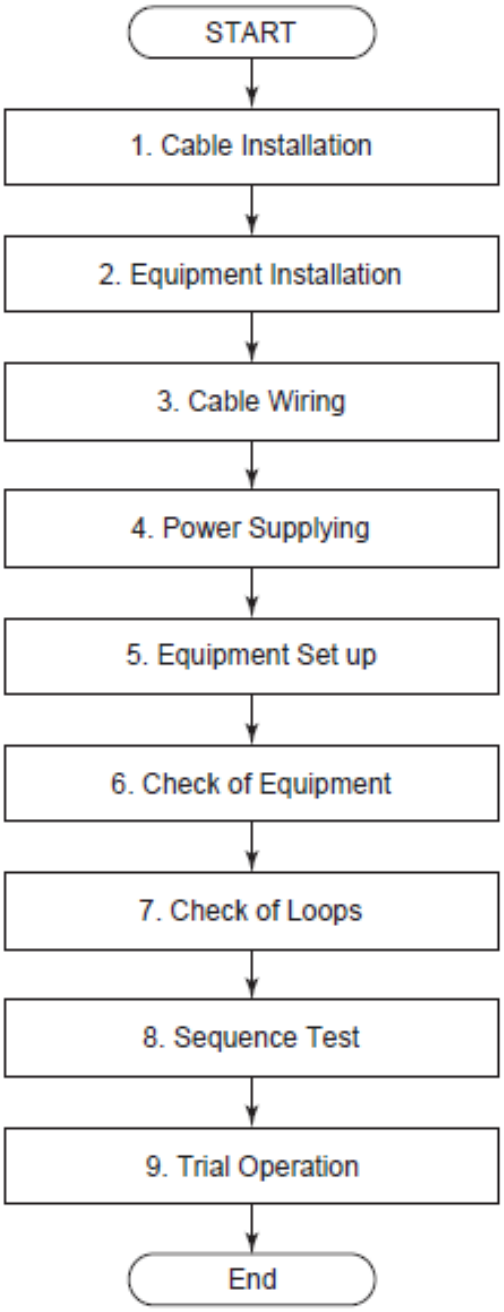

Figure 4 – Start-up

5 OPERATIONS

Operational requirements are defined by the End-user. Normally this will be included in the overall plant operation procedures and manuals. The following paragraphs will provide brief details on the operating procedures of the SIS & FGS. The main functions that are executed by the operator are:

- Trip Reset
- Input Device Maintenance Override
- Start-up Override
- Emergency Operation
- Forcing
- Security
- Operator interfaces and system monitoring

5.1 TRIP RESET

SIS / FGS logic is designed such that if it is de-energized / energised for any reason, it can only be reset or re-energized by deliberate, momentary actuation of a reset button activated at OWS along with a sequence of event log. The SIS / FGS logic can only be reset after the hazardous demand is no longer present. In the case of trip, the operator would be required to reset the highest shutdown Hierarchy first to the lowest. This is only possible when the trip conditions are healthy again. However, in some cases, the operator needs to reset the UZ Group first before being able to reset the individual valve trip.

5.2 MAINTENANCE OVERRIDE

Throughout the operational lifetime of the SIS/FGS, overrides for sensors and other input devices are required from time to time. Maintenance override switches (MOS) shall be used to inhibit trip initiators to enable maintenance or on-line functional testing. For safety reasons, these maintenance overrides shall be allowed for input signals only and not for output signals. Maintenance overrides should not prevent actual input status from being alarmed.

As a MOS effectively renders its associated safety instrumented function (SIF) ineffectual in the event of a hazardous demand (i.e. bypassed), their use shall be strictly governed by review and Contractor's operational procedures (permit to work system) including securing the soft keys from unauthorized access.

The following by-pass and override facilities shall be provided. Two different override functions shall be available:

- Operation Override Switch (OOS)
- Maintenance Override Switch (MOS)

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

5.2.1 MOS Monitoring

The presence of active MOS monitoring is described as below:

- Activation of 'MOS' enable switch shall be communicated to OWS graphic display. Upon detection of a transition to 'MOS' switch enabled state, an alarm shall be generated on OWS & recorded in SOE.
- Each trip initiator's MOS status is indicated on graphics.
- Each trip initiator's MOS status is recorded in SOE.
- If any bypass / MOS action is performed, a common "Maintenance Override "alarm with high priority shall be displayed on OWS graphics displays.

CAUTION

The MOS function is not meant for use during normal operation.

During normal operation, all 'MOS' must be removed after the necessary maintenance works have been completed.

It is the responsibility of the Employer to ensure this is strictly followed throughout the operational lifetime of the facility and is duly incorporated into the plant operations and maintenance manual / procedures.

5.2.2 MOS Activation

The steps involved in activation of new MOS at OWS is described as below:

- Turn associated 'MOS' enable key switch to 'Enable' position.
- Apply 'MOS' to a trip initiator at OWS MOS graphic.

5.2.3 MOS Removal

The MOS condition can be removed either by disabling the respective CAP MOS enable key switch or by individually removing the MOS of each trip initiators from the OWS.

5.2.4 Emergency MOS Removal

On total failure of the OWS & communication, all active MOS's can be removed by pre-determined logic. MOS active status can be observed from the MOS status lamp on the auxiliary panel.

5.2.5 Active MOS Monitoring

The presence of active MOS monitoring is described as below:

- Activation of 'MOS' enable switch shall be communicated to OWS graphic display. Upon detection of a transition to 'MOS' switch enabled state, an alarm shall be generated on OWS & recorded in SOE.
- Each trip initiator's MOS status is indicated on graphics.
- Each trip initiator's MOS status is recorded in SOE.
- If any bypass / MOS action is performed, a common "Maintenance Override "alarm with high priority shall be displayed on OWS graphics displays.

5.3 START-UP OVERRIDE

Start-Up Inhibit is used during Plant Start-Up. When the soft button is pressed in OWS, The Low-Low Alarm will be bypassed to facilitate plant start-up. The procedure for applying a start-up inhibit of SIS system, which is located on the OWS, is as follow:

- When operating the start-up inhibit switch from the OWS, the low-low trip will be bypass.
- Deactivation of the start-up inhibit is either by manual from OWS console, or when a predefine deactivation timer has been reached or when a predefined process value has been reached for a predefined time.

5.3.1 Start-up Override Monitoring

The presence of active Start-Up override monitoring is described as below

Each Start-Up override active status, start-up bypass elapsed (duration) timer shall be monitored in OWS graphics and Process alarm summary. Refer to actual graphic design.

5.4 EQUIPMENT FAILURE HANDLING

It is required to plan the operation procedure beforehand for possible equipment failure.

For Emergency procedures below, refer section. 2.1.2 in this document.

Operation flow during the error occurrence - Engineering Guide Vol.1- IM 32P01C10-01EN.

Operations and recovery procedures during the SCS error occurrence

- Actions taken at Fatal error occurrence and recovery procedure.
- Actions taken at Major error occurrence and recovery procedure.
- Actions taken at Minor error occurrence and recovery procedure.

5.5 VALVE TRIP FACILITY

Blow down valve:

SIS interlock reset, shall be the permissive for the respective.

BDV faceplate having close switch to manually close the BDV valve, during shutdown condition,

BDV close switch on the faceplate shall not be accessible.

Shut down valve:

SDV interlock reset, shall be the permissive for the respective

SDV faceplate having open switch to manually open the SDV valve, during shutdown condition,

SDV open switch on the faceplate shall not be accessible.

5.6 INTERFACES AND SYSTEM MONITORING

The system provides the following interfaces:

- Critical Action Panel (CAP)
- System status on OWS
- System status on EWS
- LED indications on modules

5.6.1 Critical Action Panel (CAP)

A Critical Action Panel (CAP) shall be software-based control located at CCR for SIS and FGS functions. A dedicated tower type PC and screen with installed CI view/License software shall be used to control the action push buttons and monitor the trip status information.

5.6.2 System Status on OWS

The System Status Overview window display the operating mode, scans period and security level along with the operating status and connection status of CPU and I/O modules.

The System Alarm window displays a list of diagnostic information messages that notify hardware, software, and communication errors in the system as system alarm messages.

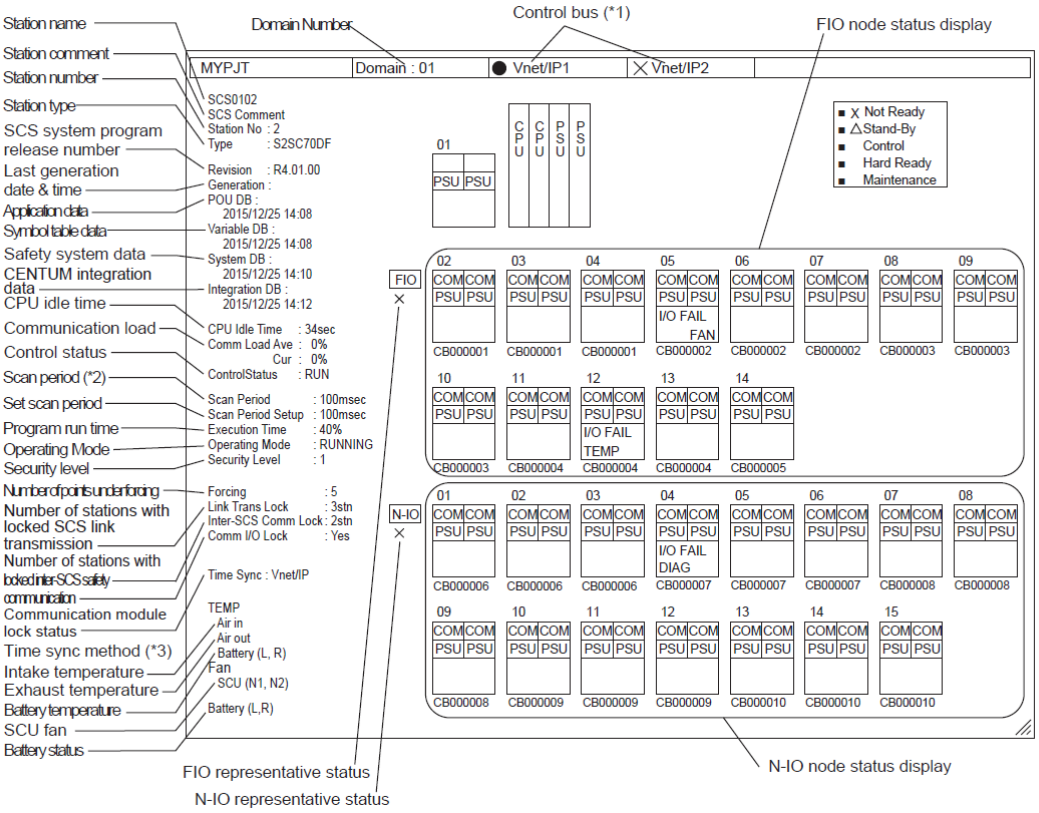

Figure 5 – System Status on OWS

5.6.3 System Status on EWS

The SCS Status Overview window displays a list of SCSs assigned to the given ProSafe-RS project. In addition to the current operating conditions of SCSs, it also displays if there is any diagnostic information message from any of the SCS diagnostic functions; it is easy to know which SCS has errors.

The SCS State Management window displays detailed information about the operating status of CPU modules and input/output modules for a single SCS. If there is an error, the erroneous area is shown using a different colour. It also displays whether there are any messages that have not been acknowledged.

The SCS State Management window allows the user to perform the following operations:

- IOM Download operation, Output Enable Operation and Start Output Module operation
- Display of detailed information of each input/output module.

5.6.4 LED Indication on modules

For health status of module, the following LEDs will be lit:

- Node Power Supplies – SYS and FLD
- Active Controller – SYNC, SCTY, HRDY, RDY, and CTRL
- Standby Controller – SYNC, SCTY, HRDY and RDY
- Active I/O Module – STATUS, ACT and DX
- Standby I/O Module – STATUS and DX

Refer Sec.8.3 for ProSafe-RS system module LED status details

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

6 MAINTENANCE

Maintenance is required to:

- Ensure the lifetime of the system.
- Maintain and detect dormant.
- Correct failures
- Keep the system up to date by updating system software and system documentation.

For the maintenance activities in general, a distinction is made between Preventive and Corrective Maintenance. (Most actions are covered when a Yokogawa maintenance contract is applicable)

6.1 PREREQUISITES

Test equipment, required for maintenance:

{This list of equipment contains the tools needed for the maintenance of the System cabinet. The tools needed for the maintenance of the valves / solenoids and the pressure transmitters should be listed in their respective documentation. If not, these tools should be added to the list here (for example pressure generator with indication}

- Clamp-on current probe
- Multimeter
- Hand tools
- Oscilloscope
- HART Handheld terminal

Note: All measurements must be performed with calibrated tools.

6.2 RECOMMENDATIONS FOR THE END USER

As indicated in the Safety Validation Plan, Yokogawa prefers an approach to safety based on the standards IEC 61508 and 61511. The safety lifecycle in which all activities which are relevant for the safety during the lifetime of the installation (hence during the engineering and construction phase, as well as during commissioning and operation, including maintenance and testing) are planned and performed according to these plans. Also, the activities should be recorded, so that they are traceable.

During the engineering and construction phases of the project Yokogawa adheres to these standards and therefore Yokogawa advises to follow the same approach during the operational life of the system.

On top of that it is required that a Proof test is performed at the intervals as specified in the reliability calculations of the Safety Validation Plan to maintain the required Safety Integrity level (SIL) for the safety loops.

A feasible approach could be the following.

- The assignment of a system custodian to co-ordinate all activities and gather all facts and reports with respect to the system.
- The installation of a system binder which contains all data (like reports of the executed maintenance and loop tests) with respect to the system.
- A maintenance planning to plan ahead for the maintenance activities over the year. Since some activities are likely to disturb the process, these should be scheduled together with a scheduled shutdown of the process. The planning of the loop tests can be combined with the maintenance planning.
- It is essential to log any system anomalies into a system logbook. This logbook typically resides close to the system or with the operators. Before executing the scheduled maintenance, the logbook must be studied to see if there are any follow-up actions.
- The system documentation (Cabinet drawings, functional block diagrams, Loop drawings, cable termination etc.) must be stored in the vicinity of the system for quick access.
- Care must be taken that every modification to the system is marked up in the site master copy of the system documentation. Any mark-ups on system drawings must be processed into revised "as built" drawings. As a minimum the drawings must be inspected on a yearly basis to verify whether updates are required.
- For every modification it must be considered if SIL loops are affected, and Safety Integrity can be guaranteed. The SVP update procedure must be followed if applicable.
- Sufficient maintenance spares must be stored on site.

6.3 PREVENTIVE MAINTENANCE

Preventive maintenance must be carried out on a regular basis to ensure an operational system that meets the requirements as specified by the contractor and / or the end user.

It is recommended to base the ProSafe-RS maintenance schedule for preventive maintenance intervals with reference to ProSafe-RS instruction manuals. A Safety Control Unit and Safety Node Unit include parts having defined life spans, which require periodical replacement.

Refer sec. 2.1.2 for recommended replacement intervals for ProSafe-RS related components - Hardware User's Guide - IM 32P06C10-01.

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

Component	Part number	Recommended replacement period	Replacement by user	Remarks
Power supply module (230VAC)	SPW482	8 years	no	
Battery pack	S9185FA	3 years	yes	Average ambient temperature of 30 C or less
		1.5 years	yes	Average ambient temperature of 40 C or less
		9 months	yes	Average ambient temperature of 50 C or less

Table 5 – Life spans for Parts of Safety Control and Node Units.

The maintenance schedule shall include 'maintenance intervals' for peripherals like workstation (EWS), cabinet fans, ventilation louvers, termination board alarms, printers, relay`s, Barriers, PSU`s, network switches & alarm devices etc. Since these components need some regular attention to ensure their lifetime and prevent failures.

It is recommended to base the maintenance intervals based on respective component instruction manuals.

6.4 FIRST LINE MAINTENANCE

The Purpose of first line maintenance is to:

- Detect dormant faults in the system, which are not detected during normal operation.
- Minimize the probability of occurrence of faults / failures from affecting the normal operations.

6.4.1 ProSafe-RS System

The ProSafe-RS system is self-testing (built in diagnostics), due to the fail-safe nature of the cards, i.e., that a failure at any point of the system will cause a trip and thus the operator is warned.

During maintenance undetected defects can be found but could only be non-safety related due to the fail-safe nature of the ProSafe-RS system. They may however have a degrading effect on the system availability due to an increase in nuisance actions.

Refer sec. 2.1.2 for procedures and precautions when maintaining ProSafe-RS devices and field devices - Engineering Guide Vol.1- IM 32P01C10-01EN.

Outputs enable:

When an output channel goes to fault, a channel fault alarm is generated, and the CPU mode changes from 'running' to 'waiting'.

In the event where the outputs (digital output, analogy output) are disabled due to channel fault / failure, the output enable operation needs to be performed upon recovery from the fault. (e.g.: after output card replacement, final element replacement or line fault recovery). This can be performed via EWS.

Refer sec. 2.1.2 of this document for output function in the event of initial power or start-up of controller (cold start) - Engineering Guide Vol.1- IM 32P01C10-01EN,

The system and process alarms are issued upon online diagnostics of any fault in the I/O channel depending on the I/O parameter configuration where the settings are enabled for detection. The outputs are disabled if any fault is detected in the output channel.

The channel fault alarms shall be 'continuously' monitored and attended by plant operation and maintenance team. Upon recovery of output channel fault, it is the plant operational / maintenance responsibility in carrying output reset (output enable) function at engineering station.

I/O Module Handling:

Handling of I/O modules and its connections during maintenance shall be performed cautiously in a simplex configuration to avoid 'spurious' trip.

Online Replacement of Modules:

When system is in operation, if it is necessary to install or remove the modules, cables, connectors, Refer sec. 2.1.2 of this document, which explain how to remove or install the common modules of the Safety Control Unit -Hardware User's Guide - IM 32P06C10-01.

The dual-redundantly configured modules (such as PSU, CPU, ESB Modules) can be removed and installed one by one without turning off the power supply to the safety control unit. The detailed procedures for the following modules are explained therein:

- Power Supply Module
- Processor Module
- ESB Bus Coupler Module
- ESB Module

6.4.2 Power Supply

Measure the voltage on the 24 Volts DC power supply units. Ensure the output of Power supply units is within voltage range specified in the label of the equipment, related documentation, and design setting.

For proper operation of the I/O module, the voltage setting must be as listed below:

- DC operating voltage for I/O module: 24VDC +20% and -10%
- DC operating voltage for safety relay: 24VDC +15% and -10%
- DC output voltage design setting at DC PSU: 22.6 to 28.8VDC
- The design output voltage setting at DC PSU is 22.6 to 28.8V DC considering the voltage drop between PSU output and system / marshalling cabinet wiring field output. This voltage setting is also labelled on the PSU equipment for reference during maintenance.
- DC Voltage (the measurement point is at 24VDC power distribution terminal in each cabinet. Refer to the cabinet drawing for details): 24VDC +20% and -10%
- Use the Cabinet Electrical drawings (refer to respective cabinet drawings) to determine the test points.

Power supply check is advised to be carried out at a frequency as per plant maintenance schedule.

6.4.3 Environmental Conditions

Refer sec. 2.1.2 to document ProSafe-RS installation guidance (TI 32P01J10-01EN) for the Environmental conditions of supplied products for the project. Refer sec 6.4.1

6.4.4 Cleaning

Accumulation of dirt and dust prevents efficient heat dissipation and may cause system failure or equipment breakdown. Cleaning involves brushing or vacuuming to restore cooling efficiency that may have been degraded by accumulated dust.

When cleaning electrical components these components must be isolated from the power supply or must be shut down before cleaning. If this action will certainly disturb the process or bear a great risk doing so, then this activity should be carried out during shutdown maintenance, see Sec.6.5.3. Be careful not to disturb wiring and jumpers on associated hardware.

Clean PC screens with a soft cloth lightly moistened with a mild detergent solution. Do not use any type of abrasive pad, scouring powder or solvent, such as alcohol or benzene. Do not rub, touch, or tap the surface of the screen with sharp or abrasive items, like a ball point pen or a screwdriver. Otherwise, this can result in damages to the screen.

Cleaning is to be carried out as soon as dust accumulation is noticed; inspect at a frequency of once per month or as per plant maintenance schedule.

6.4.5 Air Filters

Air filters in cabinets, PCs and other equipment must be cleaned or replaced regularly to ensure good air flow.

Cleaning or replacement of air filters is to be carried out as soon as dust accumulation is noticed; inspect as per plant maintenance schedule.

6.4.6 Hazardous Area Equipment

Refer to and comply with precautions and conditions for the maintenance of equipment in hazardous area as stated in the certification conditions. In general, the following precautions shall be observed.

Replacement of Fuse:

- The specified fuse must be used for replacement.
- Before replacing the fuse, confirm if there's no dangerous gas, and the power supply is OFF.

Maintenance:

- The maintenance work should be done only by operators who received special training.
- Before starting the maintenance work, confirm that there is no hazardous gas present.

Modification:

In case of any modification in design and components, the hazardous certification must be reassessed by EPC / Employer.

6.4.7 Spare Parts

The Employer must inspect the system spares on their status or have this done by Yokogawa under the maintenance and support agreement.

It is recommended that parts with damaged packing be returned to Yokogawa for re-test and repacking.

Inspection is advised to be carried out at a frequency of once per year or as per plant maintenance schedule.

6.4.8 Routine checks

Routine maintenance is performed by visually checking the status lamps of the equipment or by checking the SCS State Management window

Refer sec. 2.1.2 to document Hardware User`s Guide (IM 32P06C10-01EN) Section E2 for more details. Check the ProSafe-RS system status on the EWS or OWS system alarm and diagnostics display. Investigate and correct any alarms/ errors.

6.4.9 System Documentation

The system documentation is advised to be stored near the system for quick references. Care must be taken that every modification to the system is marked up in the master copy of the system documentation on site. Any mark-ups on system drawings must be processed into revised "as built" drawings. To be able to track any problem that may have occurred during the preceding operational period it is essential to enter any system discrepancy in a system logbook. The assignment of a system custodian on site is recommended to keep track of the system maintenance history.

Inspect drawings and documents on at a frequency of once per six months to verify if updates are required.

6.4.10 Routine PC Housekeeping

To maintain the PCs in good working order, some basic housekeeping activities are recommended.

SOE Message Cache:

The message cache service function continuously collects the SCS SOE and diagnostic information (due to automatic data acquisition configuration) and saves it as cache file at EWS. All the SCS Controllers are configured for automatic data acquisition at EWS.

Make sure that the disk used for DISK Cache by the Message Cache Service always has enough free space. (Default maximum Disk capacity: 800MB) Monitoring for the Maximum Capacity is performed every 30 seconds. If the disk usage for the disk cache exceeds the Maximum Capacity, oldest files are deleted to keep the usage rate of the disk cache at 98% to 100%.

The cache file is stored for each station. “SOE including Trip” and “Diagnostic Information messages” are stored separately in the cache file. If old cache files are required to be retained, manually save the files in a separate folder or media from the [Save Disk Cache] dialog box. To view the disk cache usage rate, use the Message Cache Tool: click [DISK Cache] in the tree view.

Suggest monitoring the Disk Cache usage rate via the Message Cache Tool as per plant maintenance schedule. On reaching 50%, existing files can be backed up and deleted from the hard disk as part of Housekeeping.

6.4.11 Operation History

Access Control and Operation History Management Software Package is used in each ENG to set the operation rights of engineers who operate the safety engineering PC (ENG), as well as to record the operation history. This package is divided into the Access Control function and Operation History Management function.

Operation History Management:

This function is used to record the operation history of software on ENG. It allows an engineer to view the operation history; for example, who operated what, when, how, and why. The recorded operation history can be used for engineer job handover and troubleshooting and analysis. As modification files accumulate in the operation history database, the amount of free disk space gradually decreases. When the remaining free space almost reaches to the specified free disk space, a dialog box appears to alert low disk space. When the remaining free space becomes lower than the specified free disk space, a dialog box appears to prompt backup and further operations to log the operation history cannot be performed. When an alert dialog box appears, the data backup shall be carried out.

Although the modifications activity of safety instrumented system are carried out on demand basis (not regular), the impact on modification file size insignificant.

Suggest monitoring the 'amount of free disk' where 'Operation History' files are stored on quarterly basis or as per plant maintenance schedule. On reaching 50%, existing files can be backed up and deleted from the hard disk as part of Housekeeping.

6.5 SHUTDOWN MAINTENANCE

6.5.1 ProSafe-RS System

In the event of initial power or start-up of controller (cold start), all the outputs (digital output & safety communication outputs) are disabled by system design. This requires the output to enable operations to be performed after completion of system power up and when the system is ready to go into operation.

6.5.2 System status

First check the system status on the Critical Action Panel, EWS diagnostics tool and PCS system. Investigate and correct any failures e.g., fuse failure, line fault, MCB, PSU & ELM fault etc.

6.5.3 Cleaning

Refer Sec.6.4.4 for 'cleaning' to be carried out during shutdown maintenance

Visual / Mechanical inspection

Mechanical inspection includes the following checks for the ProSafe-RS system:

- Check if the terminals are firmly closed.
- Check if electrical wiring and cables are not trapped and firmly connected to their termination assembly.
- Check for signs of corrosion on connecting parts, terminals, etc.

- Check proper function of door hinges and locks.
- Check connection of Communication cables (ESB bus, ESB bus or optical ESB bus, Vnet/IP, etc.).
- Check ELM alarm.

6.5.4 Field Power Supply Redundancy Check

Power check includes the following checks,

- Check the LED status of the primary/redundant power supply.
- Check the voltage levels of both power supply and make sure the power distribution wiring is connected.
- Switch off primary power supply and conduct the check related to system and I/O.
- Once completed the checks, switch on primary power supply.
- Check the voltage levels of both power supply and follow the same for the secondary power supply.
- Check the current of both power supply and follow the same for the secondary power supply.

6.5.5 Functional check of inputs

Test the inputs by simulating an alarm. The actual status will appear on the OWS.

6.5.6 Functional check of outputs

Outputs can be tested without operating the valves or solenoids by removing/ disconnect the related fuse terminals.

6.5.7 Valves and Solenoids

There are probably no actions other than the Proof test actions. Refer the section 7.2

6.5.8 Pressure Transmitters

If the transmitters are in voted configuration, probably all actions are possible to do “without disturbing the process”.

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as “NOT CONTROLLED” copy

7 PROOF TESTING

7.1 GENERAL

In order to maintain the required safety integrity level for the safety loops, proof tests must be performed at intervals as specified in the reliability calculations in the Safety Validation Plan. The proof test frequency can also be found on the Safety Certificate.

It is the End User's responsibility to execute these proof tests and to record the results if they aim to comply with IEC 61508 / IEC 61511. This proof testing must be performed by a well-trained and skilled engineer.

Note that the following instruction provides typical system proof test information. It can be used by the client to develop their detailed proof testing procedures required to maintain the SIL.

It should be noted that according to IEC-61508 the entire safety loop must be proof tested, from field sensors up to and including the final elements.

In analogy with the Maintenance there are tests that can be done without disturbing the process and there are tests that will disturb the process.

7.2 RECOMMENDATIONS FOR THE END USER

Pre-check:

- Permit(s) to work shall be obtained before starting the Proof test.
- Prior to proof testing, confirm preventive maintenance checks (e.g. power supply limits, redundancy check) for systems separately as per detailed in Sec.6.
- For redundant configuration, manufacturer recommendation of Proof test shall be considered. Logic solver shall be tested for redundant configurations as applicable for the project.
- Ensure prior to proof test ensure the healthiness of the system components and components in the loop without any diagnostics error.

Procedures:

- The design of Proof test procedures shall be based on firm understanding of the SIF architecture including dependencies on other SIF and any other precautions.
- Proof testing shall be performed by a well-trained and skilled engineer.
- Output devices undergoing Proof testing may be de-energized or energized depending on type of output logic and fail-safe configurations. Hence End-user shall generate the isolation philosophy (e.g. energized/de-energized state, voting, override and bypass valves) for each SIF to conduct Proof Test at required intervals.
- It is of vital importance to verify that Proof testing will not cause spurious trips or hazardous situations in the field.
- The end user shall decide method of Proof test (e.g. online, offline etc.) depends on isolation philosophy for selected SIF.

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

- Proof test requirements specified in sensor and final element equipment manual shall be taken into consideration while developing Proof test procedures by End User.
- Manual bypass switches (Maintenance override) for sensor overriding shall be used with caution during functional testing as this will override the action of the safety function. Manual bypass switches shall not be used for disabling shutdown valves from closing during the testing of final elements.
- Locking and forcing of inputs or outputs within the logic system to simulate inputs or activate outputs shall not be considered the equivalent of testing and prohibited from using for testing.
- Calibrated test equipment shall be used during Proof testing.
- Proof test shall include confirming SIF response time.

Sensor:

- Proof testing for sensors shall include alarm, trip, fault conditions (e.g open, short, burnout), deviation for voted condition etc.
- Manual overrides for sensors limit the coverage for proof testing and should not be considered for the test strategy unless adequate proof test coverage and overlaps is ensured by alternate test strategies.
- Proof test shall include testing of auxiliary console components (e.g. push buttons, key switches)

Logic Solver:

- Proof test shall include I/O interfaces components (e.g Isolator/barrier, surge arrestor, interposing relay etc). The manufacturer's safety manual and instruction manuals shall be used to develop proof test procedures considering device specific requirements.
- ProSafe-RS test interval is 10 years.
- In practice, shorter Proof test intervals are sometimes required for the input and output field devices (e.g., every 6 months) than for the ProSafe-RS. Testing the entire safety loop together with a field device automatically includes the test of the ProSafe-RS. End-user shall analyze and establish testing procedures for ProSafe-RS in the aspect of full test coverage requirement for ProSafe-RS alone (e.g application logic)

Final Element:

- Proof test shall include testing of auxiliary console components (e.g., lamps and buzzer).
- Partial Stroke Test (PST) is a complementary testing method to the Full Stroke Test (FST). In essence, the partial stroke test is a testing method whereby a portion of the shutdown valve assembly is tested more frequently than the full test rate. The test involves moving the valve a small percentage ranging from 10% to 30%, which tests a portion of the shutdown valve failure modes. The remainder of the failure modes shall be tested during a full-stroke test.
- For those SIS valves with PST function, when performing the valve PST, limit switch status may not be available for the duration of the test.

- The leakage of the shutdown valves must be tested when this valve is in its closed position.
- Proof testing for final element shall include any open discrepancy test, closed discrepancy test, if designed accordingly.

Result:

The results of Proof testing shall be recorded and maintained for the purposes of periodic reporting, audit, and historical analysis.

7.3 PROOF TEST COVERAGE - STRATEGIES FOR PROOF TESTING

It is end user responsibility to identify pipe to pipe testing strategy or segmented testing strategy for each SIF depending on established test procedures.

7.4 RECORDING SIF ACTIVATION DURING PROCESS DEMAND:

It may be noted that when a SIF is activated as a result of a real process demand, the same can be recorded as a proof test of the SIF.

However, this may not provide complete test coverage (like redundant parts of the system) and therefore these should be covered by proof testing procedure.

7.5 SIS TEST (PROSAFE-RS)

To maintain the ProSafe-RS system in a state of good operational readiness, it is essential that proof tests are carried out at intervals to ensure the proper functioning of the systems and associated field devices.

Complete safety critical loop functions of the SIS with their executive actions (activation of relays, solenoid valves, final elements etc.) must be tested including field input devices and final elements to ensure the SIS is maintained in a state of good operational readiness.

7.5.1 Execution of Proof Test

According to IEC-61508, all Safety Loops (SIF) have to be proof tested.

Proof Test Interval requirement for each plants Logic Solver, Sensors & Final Elements are specified in Customer Specification document (e.g. SRS).

The IEC-61508 requires that the complete safety critical loops are tested, including field input devices (e.g. detectors) and final elements (valves etc.). Field and final element equipment is not in scope of Yokogawa reliability calculations, and may have different proof test requirements (e.g. test intervals).

During proof testing of the ProSafe-RS system, trips might be generated. Therefore, a complete proof test can only be done with precautionary measures during shutdown periods.

7.5.2 Proof Test for ProSafe-RS

A proof test is a periodic test to verify that the functions of safety loops, which consist of a sensor, logic solver and final element, work without fails. The proof test items for logic solvers (ProSafe-RS) are explained below.

The ProSafe-RS has been designed to meet the requirements for PFD of SIL 3 that are defined as a fraction of 10-4 to 10-3 in the IEC 61508, with the condition that the interval between proof tests is 10 years.

Checking the Channels of Input / Output Modules:

Change the input value or output value of each channel of the modules and check if the modules work as intended. For dual-redundant modules, check on both modules.

I/O channels are tested as part of SIF proof testing procedures either pipe to pipe test or segmented testing methods.

I/O channel values shall be monitored in safety engineering station maintenance tool (IO lock window, application logic level) and/or operator interfaces (faceplate).

Control Right Switch Over (for Redundant CPU Modules and Input / Output Modules):

To ensure high availability, use the following procedures to check that switch overtakes place properly on dual-redundant modules.

Input/output Modules

Use the IOM Control Right Switching Tool to make switch over on AIO/DIO modules. This tool switches the control right of dual-redundant AIO/DIO modules from the ENG. By using this tool, the control right will be switched over to the modules on the standby side.

It is not recommended to remove the cables or terminal blocks from the active modules for this test so to avoid human mishandling.

Refer Sec. 2.1.2 on the use of the IOM Control Right Switching Tool.

Do not remove and put back the applicable AIO/DIO module while automatic IOM download is being executed, which will lead to module failure. The resolution is to perform manual IOM download at engineering station and then remove and reinsert the module after the completion.

CAUTION

Output devices undergoing proof testing may be de-energized or energized depending on type of output logic and fail-safe configurations. The default design of the SIS outputs are de-energized to safe unless otherwise specific design in a system.

Hence it is of vital importance to verify that this will not cause spurious trips or hazardous situations in the field. If necessary, isolate outputs to the field. The Employer is responsible for necessary procedures and actions to ensure safety.

CPU Modules

To make a switch over, press the START/STOP switch in the front of the control-side CPU Module to stop it. Press the START/STOP switch of the failed module once again to restart it. The module should start up as a standby side.

Do not pull out the CPU module online and turn off the power while the module is writing to the flash memory. Whether the CPU module is wiring can be confirmed by using LED of the CPU module. Ensure 'Vnet/IP' bus cables are always connected either removing or inserting the processor module online.

8 TROUBLE SHOOTING

The ProSafe-RS Safety Control Station (SCS) performs self-diagnosis regularly to detect hardware and software errors. It analyses detected errors and system configuration to determine the error level according to the error occurred and executes error-handling operations according to the error level.

The diagnostic management function saves/manages diagnostic information messages generated by self-diagnosis and manages the SCS status. Moreover, it notifies the operation status of the SCS to the EWS and OWS.

8.1 GENERAL

When an output trips to an (apparent) nuisance failure or when it is not possible to get the system healthy after a shutdown, the following actions can be taken to trace and solve the fault:

1. Verify on SOER which event caused the trip.
2. Verify the system diagnostics report for any error reported
3. Collect all relevant drawings related to the trip and verify that they reflect the as-built system status.
4. Verify that all inputs are in a healthy state.
5. Apply overrides on unhealthy inputs.
6. Reset the system in a hierarchical way.
7. If the fault is still present, verify if reset commands are received by checking the LED's in front of the module.
8. If the system still has not recovered find the improperly functioning module by using the termination drawings. Refer to the IO Database - SIS / F&G document for relevant section listed in Refer Sec. 2.1.2 for more detailed information.
9. Replace the card malfunctioning by another of the same type and start from step 6.

8.2 TROUBLE SHOOTING FACILITIES.

The system is provided with the following tools to find a defective part in the system:

- OWS to monitor SIS status.
- EWS to monitor system status.
- LED indications on modules.
- Inputs override facilities.
- LED Indication on Power supply modules and ELM
- LED Indication on Relay & Barrier.
- Test/disconnect terminals.

8.3 LED INDICATIONS ON PROSAFE-RS MODULES

All ProSafe-RS modules in the system are provided with LED indications. Refer Sec. 2.1.2 document Hardware User`s Guide (IM 32P06C10-01EN) for detailed information regarding the status of each LED.

8.4 EWS/OWS DIAGNOSTICS MANAGEMENT

The diagnostic management function notifies SCS diagnostic information (the diagnostic information messages and error notifications to the application logic corresponding to different levels of errors that may generate in the SCS) in response to requests from windows that handle diagnostic information. This allows checking and manipulating the information from the EWS and OWS.

"State Management Window" provides complete display of ProSafe-RS system status, faults, alarms etc in addition to comprehensive diagnostic information. Also, the software logic, IO and variable values can be monitored on-line by using "Debug" function of the Workbench software

For details regarding diagnostic messages, Refer Sec. 2.1.2 Messages Reference Manual (IM 32P02B10-01) for IOM Module Troubleshoot

This section explains the procedure for ProSafe-RS SCS I/O module failure.

If a problem occurs on I/O module, confirm the error code in the alarm message that is displayed on EWS and OWS. The Error message number is the same for EWS's Diagnostic Information Message and PCS OWS System Alarm Message. For details regarding diagnostic messages, Refer Sec. 2.1.2 for diagnostic Messages Reference Manual (IM 32P02B10-01).

The following information may be required by Yokogawa experts for further analysis of the fault occurred.

8.4.1 IOM Report

SCS Maintenance Support Tool has IOM Report Window that displays the I/O module status in detail. Diagnostic Information Message indicates the node number, slot number and channel number in the message, but the cause of the error is not displayed. IOM report has more detailed information that includes the cause of errors such as short-circuit or open circuit.

IOM report is the most useful information to make investigation. IOM Report Window of EWS has "File" button to save the IOM Report information to a text file. Make the IOM Report text file as follows:

- Save the IOM report text file during the I/O module is failed.
- If the IOM has recovered already, the information saved in IOM report becomes smaller. However, even if the IOM has recovered, make the IOM Report text file anyway.
- In case of the dual redundant configuration, make IOM Report text file for both of Active and Standby modules respectively even though one is in fail and the other one is in operation.

8.4.2 Report from SOE viewer

SOE Viewer has a function to save the SCS log to a CSV file.

- Make sure the Diagnostic Information Message of the failure is included in the SOE log.
- Make sure that the log includes as many events and alarms (Diagnostic Information Message) before and after the failure as possible.

8.4.3 I/O Parameter Settings

I/O module parameter and I/O channel parameter are required to make investigation sometimes. On EWS, I/O Parameter Builder can export CSV file that contains the I/O parameter for all I/O modules of the SCS.

The following procedures detail the export operation:

- Invoke I/O Parameter Builder.
- From File menu, File => External File => Export.
- Export dialogue box appears, then specify the file name, and save the CSV file.

8.5 OVERRIDES

For using overrides refer to section 5.2.

8.6 TEST / DISCONNECT TERMINALS

Each channel of the base plate is equipped with a disconnecting terminal to disconnect

the I/O module from the field terminal and allow for field loop testing. In the case of IS Signals, field connection to be disconnected from Barrier baseplate.

Refer to the documents listed below for more detailed information

- Typical Loop Drawing - SIS/F&G
- Respective Process area IO Database - SIS / F&G document

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

9 ATTACHMENTS

Following are the Safety system hardware components used in BLPH HOLLANDSE KUST NOORD WIND PARK Project.

9.13	-	ProSafe-RS Installation Guidance	TI 32P01J10-01EN
9.14	-	Security Standard of System Product	TI 33Y01B30-01E
9.15	Safety Control Station (S2SC70D)	A Safety Control Station (SCS) consists of Safety Node Unit (SNU) that implements safety control function by executing the application programs downloaded from the Safety Engineering Station.	GS 32P06D10-01EN
9.16	Safety Node Unit (SNB10D)	The Safety Node Unit has an interface function to transmit Analog input signals and contact signals from the field to the Safety Node Unit via an ESB bus. It also has a function to supply power to I/O modules.	GS 32Q06K10-31E

Attachment no	Model	Description	IM/GS Reference
9.17	ESB Bus Coupler Module (SEC401-S1)	ESB Bus Coupler Module connects Safety Node Units and safety node units via an ESB bus cable. This module is installed in the Safety Node Unit.	GS 32Q06L11-31E
9.18	Analog Input Module (SAI143-H63)	AI Module inputs 4 to 20mA from the field. This module has HART communication function available. One HART device is connectable for each channel. Each channel is equipped with a power supply function to the HART device. Each module has only one HART modem and is communicable concurrently with only one HART device.	GS 32Q06K30-31E
9.19	Digital Input Module (SDV144-S63)	Digital Input modules SDV144 (24 VDC, 16 channels) will process all Digital Inputs. The signal input shall be a dry contact. Relays suitable for safety operations shall be installed in the termination cabinets suitable for interfacing with the field voltage level.	GS 32Q06K40-31E
	Digital Output Module (SDV541-S63)	The SDV541 (24 VDC, 16 channels) will process all Digital Outputs. Outputs shall be without common wiring. Relays suitable for safety operations shall be installed in the termination cabinets suitable for interfacing with the field voltage level for driving solenoid valves, motors, pumps, and compressors. Digital output modules shall support line monitoring if the safety status require energizing.	
	SCB100	For Detecting disconnection failures	
	SCB110	For Detecting short-circuit failures	
9.20	Enhanced Serial Bus Cable (YCB301)	This connects the Node interface unit to the SCS through the ESB bus coupler Module.	GS 32Q06M10-31E

Attachment no	Model	Description	IM/GS Reference
	Signal Cable for Analog Modules (KS1-10/HF)	Analog Signal Cable for YKO System (for 40-40 Pins)	
	Signal Cable for Digital Modules (AKB331-M010/HF)	Signal Cable (50-50 pin), DIO Cable length 10m, special cable for SDV144 or SDV541 (for ProSafe RS).	
9.21	TB for Analog Modules (SBA4D-06)	Terminal Board for Analog (Single and dual-redundant, 16 channel x 1)	GS 32Q06L20-31E
	TB for Digital Modules (SBD4D-06)	Terminal Board for Digital (Single and dual-redundant, 16 channel x 1)

Introduction

This manual provides the overview of ProSafe-RS. Please read first to understand the product. Links are also listed to guide you to the descriptions of ProSafe-RS usage for each situation.

CI Server Integration also contains FAST/TOOLS Integration function. If FAST/TOOLS Integration is used, replace the term “CI Server” with “FAST/TOOLS” in the user’s manual.

If you are using the Field Commissioning Support Package, replace “FieldMate Validator” in the User's Manual with “Field Commissioning Support Package.”

If you are using YFGW520, replace the term “YFGW510” with “YFGW520” in the User’s Manual.

This manual consists of the following parts:

- Part A Overview of ProSafe-RS
  Provides an overview of the typical functions of ProSafe-RS. ProSafe-RS can be used either on a physical computer or on a virtual computer that is built on a virtualization platform.
- Part B ProSafe-RS Security
  Describes the security function that should first be understood when handling ProSafe-RS products.
- Appendix 1 Glossary
  A glossary of terms used in the user manual
- Appendix 2 List of links
  A list that guides you to the description of ProSafe-RS usage in typical situations.

Safety Precautions for Use

Safety, Protection, and Modification of the Product

- To protect the system controlled by the Product and the Product itself and to ensure safe operation, please observe the safety precautions described in this Manual. Yokogawa Electric Corporation ("YOKOGAWA") assumes no liability for safety if users fail to observe the safety precautions and instructions when operating the Product.
- If the Product is used in a manner not specified in the User's Manuals, the protection provided by the Product may be impaired.
- If any protection or safety circuit is required for the system controlled by the Product or for the Product itself, please install it externally.
- Be sure to confirm the specifications and required settings of the devices that are used in combination with the Product by referring to the instruction manual or other documents of the devices.
- Use only spare parts that are approved by YOKOGAWA when replacing parts or consumables of the Product.
- Do not use the Product and its accessories such as power cords on devices that are not approved by YOKOGAWA. Do not use the Product and its accessories for any purpose other than those intended by YOKOGAWA.
- Modification of the Product is strictly prohibited.
- The following symbols are used in the Product and User's Manuals to indicate the accompanying safety precautions:

Indicates that caution is required. This symbol for the Product indicates the possibility of dangers such as electric shock on personnel and equipment, and also indicates that the user must refer to the User’s Manuals for necessary actions. In the User’s Manuals, this symbol is used together with a word “CAUTION” or “WARNING” at the locations where precautions for avoiding dangers are described.

<French> Signale qu’il faut faire preuve de prudence. Ce symbole pour le produit signale la possibilité d’un danger pour le personnel et l’équipement comme un choc électrique, et signale également que l’utilisateur doit se référer au Manuel de l’utilisateur afin de prendre les mesures nécessaires. Dans le Manuel de l’utilisateur, ce symbole est utilisé conjointement avec la mention «CAUTION» ou «WARNING» aux endroits où sont décrites les précautions pour éviter les dangers.

Indicates that caution is required for hot surface. Note that the devices with this symbol become hot. The risk of burn injury or some damages exists if the devices are touched or contacted.

<French> Signale qu'il faut faire preuve de prudence avec la surface brûlante. Les appareils sur lesquels est apposé ce symbole risquent de devenir brûlants. Tout contact physique ou matériel avec ces appareils risque de provoquer des brûlures ou des dommages.

Identifies a protective conductor terminal. Before using the Product, you must ground the protective conductor terminal to avoid electric shock.

Identifies a functional grounding terminal. A terminal marked "FG" also has the same function. This terminal is used for grounding other than protective grounding. Before using the Product, you must ground this terminal.

~ Indicates an AC supply.

⎓ Indicates a DC supply.

	Indicates that a component such as a power supply switch is turned ON.
◯	Indicates that a component such as a power supply switch is turned OFF.

Notes on Handling User's Manuals

- Hand over the User's Manuals to your end users so that they can keep the User's Manuals on hand for convenient reference.
- Thoroughly read and understand the information in the User's Manuals before using the Product.
- For the avoidance of doubt, the purpose of the User's Manuals is not to warrant that the Product is suitable for any particular purpose but to describe the functional details of the Product.
- Contents of the User's Manuals are subject to change without notice.
- Every effort has been made to ensure the accuracy of contents in the User's Manuals. However, should you have any questions or find any errors, contact us or your local distributor. The User's Manuals with unordered or missing pages will be replaced.

Warning and Disclaimer

- Except as specified in the warranty terms, YOKOGAWA shall not provide any warranty for the Product.
- YOKOGAWA shall not be liable for any indirect or consequential loss incurred by either using or not being able to use the Product.

Notes on Software

- YOKOGAWA makes no warranties, either expressed or implied, with respect to the Software Product's merchantability or suitability for any particular purpose, except as specified in the warranty terms.
- Purchase the appropriate number of licenses of the Software Product according to the number of computers to be used.
- No copy of the Software Product may be made for any purpose other than backup; otherwise, it is deemed as an infringement of YOKOGAWA's Intellectual Property rights.
- Keep the software medium of the Software Product in a safe place.
- No reverse engineering, reverse compiling, reverse assembling, or converting the Software Product to human-readable format may be performed for the Software Product.
- No part of the Software Product may be transferred, converted, or sublet for use by any third-party, without prior written consent from YOKOGAWA.

Documentation Conventions

Symbols

The following symbols are used in the User's Manuals.

Indicates precautions to avoid a danger that may lead to death or severe injury.

Indicates precautions to avoid a danger that may lead to minor or moderate injury or property damage.

IMPORTANT

Indicates important information required to understand operations or functions.

TIP

Indicates additional information.

SEE ALSO

Indicates referenced content.

In online manuals, you can view the referenced content by clicking the links that are in green text. However, this action does not apply to the links that are in black text.

Typographical Conventions

The following typographical conventions are used throughout the User's Manuals.

Commonly Used Conventions throughout the User's Manuals

- Δ Mark
  Indicates that a space must be entered between character strings.
  Example:

  ```
  .ALΔPIC010Δ-SC
  ```

- Character string enclosed by braces { }
  Indicates character strings that may be omitted.

  Example:

  ```
  .PRΔTAG{Δ.sheet name}
  ```

Conventions Used to Show Key or Button Operations

- Characters enclosed by brackets [ ]
  When characters are enclosed by brackets in the description of a key or button operation, it indicates a key on the keyboard, a button name in a window, or an item in a list box displayed in a window.

  Example:

  To alter the function, press the [ESC] key.

Conventions of a User-defined Folder

- User-defined folder name enclosed by parenthesis ( )
  User definable path is written in a pair of parentheses.

  Example:

  ```
  (RS Project Folder)\SCS0101
  ```

If the RS Project Folder is `C:\MYRSPJT`, the above path becomes `C:\MYRSPJTSCS0101`.

Drawing Conventions

Drawings used in the User's Manuals may be partially emphasized, simplified, or omitted for the convenience of description.

Drawings of windows may be slightly different from the actual screenshots with different settings or fonts. The difference does not hamper the understanding of basic functionalities and operation and monitoring tasks.

Explanation of Hardware and Software Behaviors in the User's Manuals

In the User's Manuals, system behaviors are explained assuming that the latest versions of YOKOGAWA software and hardware at the time of publication of the User's Manuals are installed.
If additional precise information about the safety of legacy versions of software or hardware is required, a link to the corresponding explanation is provided. Please refer to the information according to your system.

Definitions of Node and Module Terms

In the User's Manuals, nodes and modules are referred to by using collective terms, another terms, or abbreviations based on the following definitions:

- Definitions of nodes
  - Node: A node is a collective term for an FIO node and an N-IO node.
  - FIO node: This is a collective term for a safety control unit, a safety node unit, and a unit for optical ESB bus repeater module.
  - CPU node: This is another term for a safety control unit. The abbreviation of safety control unit is SCU.
  - I/O node: This is another term for a safety node unit. The abbreviation of safety node unit is SNU.
  - N-IO node: This is a collective term for a node interface unit and an N-IO I/O unit. The abbreviation of node interface unit is NIU.
- Definitions of modules
  - I/O module: This is a collective term for an FIO I/O module and an N-IO I/O module.
  - FIO I/O module: This is a collective term for an analog I/O module and a digital I/O module for FIO, and a communication module.
  - N-IO I/O module: This is a collective term for the modules that can be mounted on an N-IO I/O unit.
  - AIO/DIO module: This is a collective term for an analog I/O module, a digital I/O module, and a universal type I/O module.
  - Analog I/O module: This is a collective term for an analog input module and an analog output module.
  - Digital I/O module: This is a collective term for a digital input module and a digital output module.
  - Universal type I/O module: This is a collective term for the I/O modules for which the channel signal category can be changed by software.

- Input module: This is a collective term for an analog input module, digital input module, and a universal type I/O module with defined input channels.
- Output module: This is a collective term for an analog output module, digital output module, and a universal type I/O module with defined output channels.
- Communication module: This is a collective term for a serial communication module, an Ethernet communication module, and a fire and gas communication module.

Full Names and Simplified Terms

In the User's Manuals, simplified terms listed in the following table are used.

Table Info-1 Full Names and Simplified Terms

Full Name	Simplified Term
Automation Design Suite	AD Suite
Automation Design Organizer	AD Organizer
Automation Design Server	AD Server
Automation Design project	AD project
Automation Design Master Database	ADMDB
Automation Design Suite Administration Tool	ADS Administration Tool
iDefine for ProSafe-RS	iDefine
Modification Package	ModPack
SCSV1-S (SCS supporting the SSC10S/SSC10D safety control units)	SCSV1
SCSP1-S (SCS supporting the SSC50S/SSC50D safety control units)	SCSP1
SCSP2-S (SCS supporting the SSC60S/SSC60D safety control units)	SCSP2
SCSP3-S (SCS supporting the S2SC70S/S2SC70D safety control units)	SCSP3
SCSL2-S (SCS supporting the L1SC70S/L1SC70D safety control units)	SCSL2
SCSU1-S (SCS supporting the SSC57S/SSC57D safety control units)	SCSU1

Copyright and Trademark Notices

All Rights Reserved

The copyright of the programs and online manuals contained in the software medium of the Software Product shall remain with YOKOGAWA.

You are allowed to print the required pages of the online manuals for the purposes of using or operating the Product; however, reprinting or reproducing the entire document is strictly prohibited by the Copyright Law.

Except as stated above, no part of the online manuals may be reproduced, transferred, sold, or distributed to a third party in any manner (either in electronic or written form including, without limitation, in the forms of paper documents, electronic media, and transmission via the network). Nor it may be registered or recorded in the media such as films without permission.

Trademark Acknowledgments

Appendix

Appendix 1. Glossary.....App.1-1
Appendix 2. List of links.....App.2-1

A. Overview of ProSafe-RS

ProSafe-RS is the Safety Instrumented System (SIS) comprising Safety Control Station (SCS) and Safety Engineering PC (SENG).

ProSafe-RS is the Safety Instrumented System that meets SIL 3 of the Safety Integrity Level (SIL) defined by IEC 61508. The lineup of products includes ProSafe-RS Lite, which meets Safety Integrity Level up to SIL 2.

In this User's Manual, the name of ProSafe-RS Lite may be used to describe products classified as ProSafe-RS Lite.

This section describes the following topics to give an overview of ProSafe-RS:

- Operating Environment
- System configuration of ProSafe-RS
- Overview of the SCS
- Configuration of safety system engineering function
- Configuration of Maintenance Function
- Configuration of the SCS Maintenance Support Tool
- Virtualization platform

A1. Requirements

This section explains the hardware and software requirements. It also explains the software that can collaborate with ProSafe-RS and software that can co-exist on the same computer.

SEE ALSO For more information about hardware on which the virtualization platform runs, and Yokogawa system products running on virtualization platform virtual machines, refer to:

IA system products virtualization platform (GS 30A05B10-01EN)

A1.1 Hardware requirements

This section describes the hardware environment used in a ProSafe-RS system.

If CENTUM software is also installed on the same computer, the computer must also meet the requirements for CENTUM.

Likewise, if iDefine software is installed on the same computer, the computer must also meet the requirements for iDefine.

SEE ALSO For more information about the hardware requirements of the computer where iDefine is to be installed, refer to:

2., "System Requirements" in iDefine Installation Guide (PR03076-MAN-991_01)

Hardware requirements for SENG

You must ensure that the computer that is used as SENG meets the hardware requirements as shown in the following table. Conditions will differ depending on the package being used.

- When using the Engineering Server Function:

Table A1.1-1 Hardware requirements for SENG (Windows 10)

Component	Requirements
CPU	Intel Core i5 equivalent or above
Main memory	8 GB or more
Hard disk space	Available space of at least 100 MB x the number of SCS units

Table A1.1-2 Hardware requirements for SENG (Windows Server 2016, Windows Server 2019, Windows Server 2022)

Component	Requirements
CPU	Xeon 4 core (2.2 GHz) equivalent or above
Main memory	8 GB or more
Hard disk space	Available space of at least 100 MB x the number of SCS units

- When using the Safety System Engineering and Maintenance Function:
  When installing the Engineering Server Function in the same computer, observe the hardware requirements for the Engineering Server Function. Also be sure to total the required space available for the hard disk space.

Table A1.1-3 Hardware requirements for SENG (Windows 10)

Component	Requirements
CPU	Intel Core i5 equivalent or above
Main memory	8 GB or more
Hard disk space	Available space of at least 60 GB

Table A1.1-4 Hardware requirements for SENG (Windows Server 2016, Windows Server 2019, Windows Server 2022)

Component	Requirements
CPU	Xeon 4 core (2.2 GHz) equivalent or above
Main memory	8 GB or more
Hard disk space	Available space of at least 60 GB

- When using the SOE Viewer Package, SOE OPC Interface Package, and Forced I/O Viewer Package:
  When installing the SOE Viewer Package or the SOE OPC Interface Package on the same computer where the Engineering Server Function, or the Safety System Engineering and Maintenance Function is installed, observe the hardware requirements for each function. Also be sure to total the space required by each function and available for the hard disk space.

Table A1.1-5 Hardware requirements for SENG (Windows 10)

Component	Requirements
CPU	Intel Core 2 Duo processor (2.13 GHz) equivalent or above, or Xeon Dual Core (2.0 GHz) equivalent or above
Main memory	4 GB or more
Hard disk space	• Available space of at least 20 GB (required) • Available space of at least 40 GB (recommended)

Table A1.1-6 Hardware requirements for SENG (Windows Server 2016, Windows Server 2019, Windows Server 2022)

Component	Requirements
CPU	Xeon Dual Core (2.93 GHz) or higher (mandatory)
Main memory	4 GB or more
Hard disk space	• Available space of at least 20 GB (required) • Available space of at least 40 GB (recommended)

The components for which requirements are same irrespective of OS and license conditions are summarized in the following table.

Table A1.1-7 SENG hardware requirements (components for which requirements are the same for all the conditions)

Component	Requirements
Display	• When using a square monitor, a resolution of at least SXGA (1280x1024), True Color (required) • When using a wide-screen monitor, a resolution of at least WXGA+ (1440×900), True color
Graphics	DirectX 9 graphic processing unit or equivalent, and supports the following (mandatory): • Windows Driver Display Model (WDDM) • Pixel Shader 2.0 • 32 bits per pixel • 128 MB graphic memory
Peripheral unit	• DVD-ROM drive (mandatory) • 1 PCI Express slot is necessary for the Vnet/IP interface card (mandatory) (*1) • Mouse (mandatory)

*1: When connecting the computer to the Vnet/IP.

Hardware requirements for a file server

The hardware requirements for the computer used as a file server are as follows:

Table A1.1-8 Hardware requirements for a file server (Windows Server 2016, Windows Server 2019, Windows Server 2022)

Component	Requirements
CPU	2 GHz or higher
Main memory	2 GB or more

Continues on the next page

Table A1.1-8 Hardware requirements for a file server (Windows Server 2016, Windows Server 2019, Windows Server 2022) (Table continued)

Component	Requirements
Hard disk space	• Available space of at least 20 GB (required) • Available space of at least 50 GB (recommended) However, when placing the history management database on the hard disk, an additional available space of at least 60 GB is recommended
Display	SuperVGA (800 x 600) or higher (mandatory)
Peripheral unit	• DVD-ROM drive (mandatory) • Network adapter (mandatory)

A1.2 Software requirements

This section describes the software requirements for SENG. It also explains the software that can collaborate with ProSafe-RS and software that can co-exist on the same computer.

Software requirements for SENG

This section describes the software requirements for SENG.

Supported OS

Windows OS versions to be supported by ProSafe-RS are as follows:

- Windows 10 Enterprise 2016 LTSB (64-bit) (*1) (*2)
- Windows 10 IoT Enterprise 2016 LTSB (64-bit) (*1)
- Windows 10 Enterprise LTSC 2019 (64-bit) (*1) (*2)
- Windows 10 IoT Enterprise LTSC 2019 (64-bit) (*1)
- Windows 10 Enterprise LTSC 2021 (64-bit) (*1)(*2)
- Windows 10 IoT Enterprise LTSC 2021 (64-bit) (*1)
- Windows Server 2016 Standard (64-bit)
- Windows Server 2019 Standard (64-bit)
- Windows Server IoT 2019 Standard (64-bit)
- Windows Server 2022 Standard (64-bit)
- Windows Server IoT 2022 Standard (64-bit)

*1: For these models, functions are not updated and only security patches and hotfixes are provided. Exercise caution because these models are functionally different from other Windows 10 models.
*2: These models are sold only with volume licenses.

Before installing ProSafe-RS, make sure that a Windows OS version and service pack appropriate for the ProSafe-RS software release number are installed on the computer.

In this manual, whenever Windows 10, Windows Server 2019, or Windows Server 2022 is mentioned in the explanations hereafter, the IoT versions are also included.

IMPORTANT

- On a Windows pre-installed computer, various Windows utilities and other software may have been installed in addition to the Windows OS. These additional functions are not only unnecessary for SENG but also can disturb its operations. To avoid disturbance to operations, reinstall the Windows OS.
- It is assumed that security patches are applied according to the customer's security policy. YOKOGAWA recommends to apply security patches to ProSafe-RS systems. It is recommended to apply all required security patches before the system goes into operation and also apply security patches that are released after the system went into operation as promptly as possible. YOKOGAWA offers security patch application services. Contact YOKOGAWA Service for more information.
- When using Windows 10 Enterprise 2016 LTSB, Windows 10 Enterprise LTSC 2019, and Windows 10 Enterprise LTSC 2021 computers, customize the Windows settings during installation of Windows 10.

SEE ALSO For more information about the procedure for the customization at installation of Windows 10 Enterprise 2016 LTSB, Windows 10 Enterprise LTSC 2019, and Windows 10 Enterprise LTSC 2019, refer to:

Appendix 5., “Customization at Installation of Windows 10” in Installation Guide (IM 32P01C50-01EN)

.NET Framework

When the ProSafe-RS software is installed, .NET Framework is automatically installed. However, .NET Framework included in the ProSafe-RS software medium will not be installed automatically if a newer version has already been installed in the computer, to avoid downgrading of .NET Framework.

The following table shows the version of supported .NET Framework for each Windows OS.

Table A1.2-1 Version of supported .NET Framework

Windows OS	Version of supported .NET Framework
Windows 10	.NET Framework 4.8
Windows Server 2016	
Windows Server 2019	
Windows Server 2022	

Software that can coexist with ProSafe-RS

The ProSafe-RS software can coexist with the following software programs.

The following table lists the software that has been confirmed to run without affecting the operation of ProSafe-RS when installed on the same computer.

IMPORTANT

Use only the volume license version of Microsoft Word and Microsoft Excel.

Table A1.2-2 List of software that can coexist with ProSafe-RS

Classification	Software name	Version (*1)(*2)(*3)	Remarks
Spread sheet	Microsoft Excel (*4) (*5)	2021, 2019 (*6) (*7), 2016 (*8)	32-bit/64-bit (*9)
Word processor	Microsoft Word (*4) (*5)	2021, 2019 (*6) (*7), 2016 (*8)	32-bit/64-bit (*9)
WWW browser	Microsoft Internet Explorer	11	
	Microsoft Edge (*10)		
Security	Yokogawa standard antivirus software	-	
	Standard Whitelisting Software for Endpoint Security	-	
Document viewer	Adobe Acrobat	2020	Used for the Instruction Manual Package
	Adobe Acrobat Reader	DC, 2020	

*1: Please confirm the required operation environment of each software for OS on which each software operates.
*2: SP is an abbreviation of Service Pack.
*3: The software version has been confirmed at the time of the release of this document. For more information about the latest supported version, contact YOKOGAWA.
*4: If CENTUM software is installed on the same computer, make sure that installed software also meets the software requirements for CENTUM.
*5: Only the volume license version is subject to operation guarantee.
*6: Excel/Word version 2019 or 2021 works only on the following OS:

- Windows 10 Enterprise LTSC 2019
- Windows 10 Enterprise LTSC 2021
- Windows Server 2019
- Windows Server 2022

*7: When installing Excel/Word version 2019 or 2021 from Office, install only the target software with the Office Deployment Tool.
*8: Supports Windows 10 Enterprise 2016 LTSB and Windows Server 2016 only.
*9: To use the 64-bit version of Word/Excel, install it before installing ProSafe-RS. If ProSafe-RS is installed already, uninstall Access Database Engine 2016, then reinstall Word/Excel and then ProSafe-RS.
*10: It is used to display the user-defined action guide. If Microsoft Edge is not installed, use Microsoft Internet Explorer.

TIP

For precautions when using Standard Whitelisting Software for Endpoint Security on virtual machines, contact YOKOGAWA.

CENTUM integration system

When ProSafe-RS is integrated with CENTUM, available ProSafe-RS functions are limited depending on the software release number of CENTUM. This section explains precautions when installing the ProSafe-RS and CENTUM software on separate computers or on the same computer.

SEE ALSO

For more information about integration with CENTUM, refer to:

B., “CENTUM integration” in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

Relationship between ProSafe-RS functions and CENTUM release numbers

When using ProSafe-RS R4.10.00, CENTUM VP of release number R6.11 or later is recommended.

For the version of the Engineering Server Function, use the version or later included in this version ProSafe-RS. If you use the old versions of the Engineering Server Function, AD Suite will not properly operate.

When using CENTUM VP of the release number that is not recommended, the following restriction applies:

Table A1.2-3 When CENTUM VP is earlier than R6.11

Limitation
• ProSafe-RS and CENTUM VP cannot be installed on the same computer.

Table A1.2-4 When CENTUM VP is earlier than R6.08

Limitation
• SIL 2 SCS cannot be defined on System View. • Operation and monitoring of SIL 2 SCS is not available from HIS.

Table A1.2-5 When CENTUM VP is earlier than R6.07

Limitation
• System alarm messages added in R4.05.00 are not displayed on HIS. The same applies to the messages that are received through an OPC server. • In the SCS Status Display view and SCS Report dialog box, the status of Operation data reset switch is not displayed. • In the SCS Report dialog box, CPU model of S2CP471 is not displayed correctly. • Even if “Skip Password Dialog Box for Manual Operation FB” is enabled in the SCS Constants Builder, the Password Input dialog box displayed when manipulating MV from HIS is not omitted.

Table A1.2-6 When CENTUM VP is earlier than R6.06

Limitation
• The SCS simulation test does not operate correctly.

Table A1.2-7 When CENTUM VP is earlier than R6.05

Limitation
• The tags of the function blocks PSI_I, PSI_R, PNI_I, PNI_R added in R4.03.10 are not displayed on HIS. • System alarm messages added in R4.03.10 are not displayed on HIS. The same applies to the messages that are received through an OPC server. • The system alarm messages to which the string “Safety Subsystem” is added in R4.03.10 is displayed without “Safety Subsystem”. In other words, the legacy message strings are displayed. The same applies to the messages that are received through an OPC server. • In the SCS Status Display view and SCS Report dialog box, number of locked safety subsystem communication I/O is not displayed.

Table A1.2-8 When CENTUM VP is earlier than R6.04

Limitation
• The instrument faceplate of mapping blocks S_HSDTR/S_GASDTR cannot be displayed in HIS. Process alarm messages are not displayed properly. • System alarm messages added in R4.03.00 are not displayed on HIS. Messages through OPC are also not displayed. • System alarm messages that are supposed to be suppressed by the alarm suppression function during device reset are not suppressed and are displayed in HIS. • System alarm messages and process alarm messages that are supposed to be suppressed by the chattering alarm suppression function are not suppressed and are displayed in HIS.

Table A1.2-9 When CENTUM VP is earlier than R6.02

Limitation
• Operation and monitoring of SCSP3 cannot be performed on HIS.

IT security setting

- You can fortify computer security. To fortify the security, select "Standard model" with the IT Security Tool at installation of both ProSafe-RS and CENTUM VP.
- If you integrate ProSafe-RS with CENTUM VP earlier than R5.01, manually relax some security items according to the IT security setting of CENTUM VP.

SEE ALSO For more information about IT Security Tool, refer to:

6.1, “IT Security Tool” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

Coexistence of ProSafe-RS and CENTUM on the same computer

Observe the following precautions when installing the ProSafe-RS and CENTUM VP software on the same computer.

- When installing ProSafe-RS R4.10.00 and CENTUM VP on the same computer, use the software of CENTUM VP R6.11 or later.
- Unless specially instructed, install the control bus driver from the ProSafe-RS software medium.
  If one of the systems has been upgraded, follow the instruction provided for each revision.
- On a computer installed with both the ProSafe-RS and CENTUM software, configure Windows settings according to the instructions in the installation manual of CENTUM.
- PROFIBUS-DP Configurator (SYCON.net/YOKO) and PROFINET Configurator (SYCON.net-A2LP/YOKO) of CENTUM VP, and PROFINET Configurator (SYCON.net-SLP/YOKO) of ProSafe-RS cannot be started simultaneously.

TIP

- PROFIBUS-DP Configurator (SYCON.net/YOKO), PROFINET Configurator (SYCON.net-A2LP/YOKO), and PROFINET Configurator (SYCON.net-SLP/YOKO) are products of Hilscher.
- The features exclusively prepared for ProSafe-RS cannot be used in the commercially available Hilscher SYCON.net.

SEE ALSO

For more information about iDefine version that can coexist with ProSafe-RS and CENTUM VP, refer to:

"■ Use of iDefine" on page A1-10

For more information about installing the control bus driver, refer to:

B3.3.1, "Installing the Control Bus Driver" in Installation Guide (IM 32P01C50-01EN)

For more information about setup of Windows with CENTUM VP, refer to:

B4.2, "Setting Up Windows" in CENTUM VP Installation (IM 33J01C10-01EN)

■ CI Server integration system

● Coexistence of ProSafe-RS and CI Server on the same computer

CI Server and ProSafe-RS software cannot run on the same computer.

● Version

When using ProSafe-RS R4.10.00, the recommended version of CI Server is R1.01 or later. However, CI Server does not support the following devices and functions:

- Mapping blocks S_HSDTR, S_GASDTR
- Fire and gas communication
- Status display of the operation data reset switch of S2CP471

■ FAST/TOOLS integration system

● Coexistence of ProSafe-RS and FAST/TOOLS on the same computer

FAST/TOOLS and ProSafe-RS software cannot run on the same computer.

● Version

When using ProSafe-RS R4.10.00, the recommended version of FAST/TOOLS is R10.04 or later. However, FAST/TOOLS R10.04 does not support the following devices and functions:

- N-IO nodes
- Mapping blocks S_HSDTR, S_GASDTR
- Fire and gas communication
- Status display of the operation data reset switch of S2CP471
- SIL 2 SCS

Use of iDefine

IMPORTANT

When using ProSafe-RS and iDefine, use ProSafe-RS R4.02 to R4.08.

If you want to use SENG to edit engineering data created with iDefine, contact YOKOGAWA.

Coexistence of ProSafe-RS and iDefine on the same computer

When using ProSafe-RS R4.03 or later, iDefine and ProSafe-RS software can coexist.

When using ProSafe-RS R4.05 or later, iDefine software can coexist on the computer where ProSafe-RS and CENTUM VP R6.07 or later software coexist. iDefine and CENTUM VP alone cannot coexist.

IMPORTANT

You cannot install iDefine software on the computer where ProSafe-RS and PRM client software coexist.

Version

The following table shows the version numbers of ProSafe-RS and iDefine that can be used in combination.

Table A1.2-10 Allowed version number combinations of ProSafe-RS and iDefine

ProSafe-RS release number	iDefine version number	Coexistence
R4.02.00	1.16.1	Not allowed
R4.03.00	1.16.2	Allowed
R4.03.10	1.16.3	Allowed
R4.04.00	1.16.4	Allowed
R4.05.00	1.16.5	Allowed, can coexist with CENTUM VP R6.07
R4.06.00	1.16.6	Allowed, can coexist with CENTUM VP R6.08 or R6.09
R4.07.00	1.16.7	Allowed, can coexist with CENTUM VP R6.08 or R6.09
R4.08.00	1.16.7	Allowed, can coexist with CENTUM VP R6.10

iDefine is a product of Trinity Integrated Systems Ltd.

SEE ALSO For more information about the software requirements of the computer where iDefine is to be installed, refer to:

2., "System Requirements" in iDefine Installation Guide (PR03076-MAN-991_01)

Use of PRM

Coexistence of ProSafe-RS and PRM on the same computer

Whether or not the PRM and ProSafe-RS software can run on the same computer is as follows:

- A PRM server and ProSafe-RS software cannot run on the same computer.
- A PRM client and ProSafe-RS software can run on the same computer. Note, however, that a PRM client cannot run on the same computer if the computer has a license of SOE OPC Interface Package of ProSafe-RS.
- If you install the PRM client on SENG that is connected to the narrowband Vnet/IP-Upstream network, you need additional Ethernet wiring for PRM client communications.

IMPORTANT

You cannot install iDefine software on the computer where ProSafe-RS and PRM client software coexist.

Precautions when installing ProSafe-RS and PRM on the same computer

When ProSafe-RS R4.03.10 and PRM are installed on the same computer, occasionally the error messages related to DTM (Device Type Manager) is displayed in the PROFINET Configurator. When you open PROFINET Configurator for the first time, the error messages are displayed in the message area of PROFINET Configurator at the time of registering GSDML.

```
GetInformation failed with device: DTM name
```

You can ignore this error message when the DTM name is not YFGW410.

Version

When using ProSafe-RS R4.10.00, the recommended version of PRM is R4.06 or later. PRM versions earlier than R4.06 cannot be installed on the same computer as ProSafe-RS. PRM versions earlier than R4.05 do not support SCSL2 station. PRM versions earlier than R3.30 do not support SCSP3 station. Also, PRM versions earlier than R3.12 cannot be connected to the narrowband mode of Vnet/IP-Upstream.

Use of Exaopc

Coexistence of ProSafe-RS and Exaopc on the same computer

Exaopc and ProSafe-RS software cannot run on the same computer.

Version

When using ProSafe-RS R4.10.00, the recommended version of Exaopc is R3.81 or later. When using Exaopc of the version that is not recommended, the following restriction applies:

Table A1.2-11 When Exaopc is earlier than R3.78

Limitation
• The system alarm messages newly added to R4.05.00 are not notified to Exaopc Client.

Table A1.2-12 When Exaopc is earlier than R3.77

Limitation
• The system alarm messages added to R4.03.10 are not notified to Exaopc Client. • In R4.03.10, system alarm messages with “Safety Subsystem” mentioned in the legacy message are notified to Exaopc Client as a legacy message without “Safety Subsystem”.

Table A1.2-13 When Exaopc is earlier than R3.76

Limitation
• The system alarm messages added to R4.03.00 are not notified to Exaopc Client. • Process alarm messages generated from mapping blocks S_HSDTR/S_GASDTR are not notified to Exaopc client successfully. • Alarm status added in the R4.03.00 cannot be acquired in the OPC interface related to inquiries of condition name. • A recover alarm message about completion of the suppression period of the chattering alarm suppression function is not notified to Exaopc client.

Table A1.2-14 When Exaopc is earlier than R3.74

Limitation
• N-IO related system alarms are not notified to Exaopc client.

Use of Exaquantum

Coexistence of ProSafe-RS and Exaquantum on the same computer

Exaquantum and ProSafe-RS software cannot run on the same computer.

Version

When using ProSafe-RS R4.10.00, the recommended version of Exaquantum is R3.01 or later. ProSafe-RS can be connected to Exaquantum R2.20 or later. However, because the versions of Exaquantum earlier than R2.60 do not support the IT security function, you must select the Legacy model to use the IT security function of ProSafe-RS.

A2. System configuration of ProSafe-RS

This section describes the following ProSafe-RS system configurations:

- System configuration of SCS that supports SIL 3
- System configuration of SCS that supports SIL 2
- System configuration where exists both SCSs that support SIL 3 and SIL 2

System configuration of SCS that supports SIL 3

SCS that supports SIL 3 consists of hardware for SIL 3. Software license for SIL 3 is used for SENG.

SIL 3 safety communication can be used between SCSs that support SIL 3.

There is also an SCS (S2SC70) that supports N-IO and safety subsystem communication.

The following figure shows an example of the system configuration of SCS that supports SIL 3.

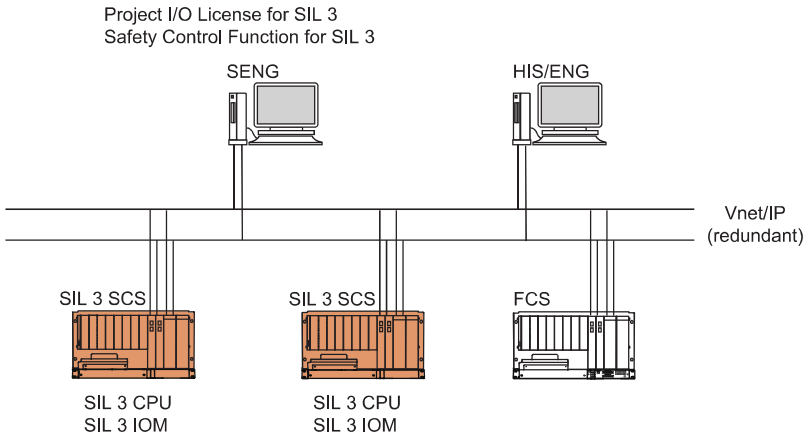

Figure A2-1 Example of the system configuration of SCS that supports SIL 3

System configuration of SCS that supports SIL 2

SCS that supports SIL 2 consists of hardware for SIL 2. Software license for SIL 2 is used for SENG.

SIL 2 safety communication can be used between SCSs that support SIL 2.

The following figure shows an example of the system configuration of SCS that supports SIL 2.

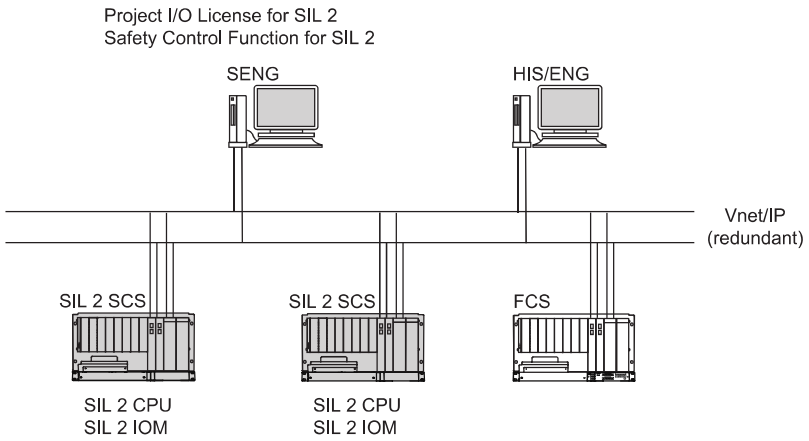

Figure A2-2 Example of the system configuration of SCS that supports SIL 2

System configuration where exists both SCSs that support SIL 3 and SIL 2

SCSs that support SIL 3 and SIL 2 can coexist in the same network.

SCS that supports SIL 3 consists of hardware for SIL 3.

SCS that supports SIL 2 consists of hardware for SIL 2.

Both software licenses for SIL 3 and SIL 2 are used for SENG. Both SCSs that support SIL 3 and SIL 2 can be engineered, tested, and maintained with a single SENG.

If safety communication is used between SCSs that support SIL 3 and SIL 2 respectively, SIL 2 safety communication is adopted.

The following figure shows an example of the system configuration where exists both SCSs that support SIL 3 and SIL 2.

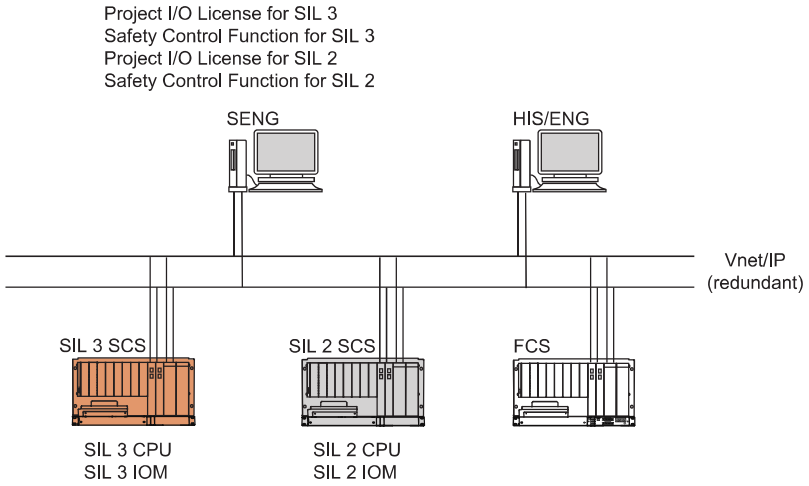

Figure A2-3 Example of the system configuration where exists both SCSs that support SIL 3 and SIL 2

A3. Overview of SCS

The ProSafe-RS SCS (Safety Control Station) is a station dedicated for safety control applications.

The SCS consists of the function that monitors the safety conditions of the plant, the application logic execution function that performs pre-determined safety operations according to each safety control request and the external communication function that communicates information with devices other than SCSs.

Classification of SCS application

In the SCS, you can create the following applications:

- Safety application
  This is an application which executes safety functions. The safety application includes application logic written in the language conforming to the IEC 61131-3 standards.

  The following programming languages defined in IEC 61131-3 are available for the SCS:

  - Function Block Diagram (FBD)
  - Ladder Diagram (LD)
  - Structured Text (ST)

- Application to connect with other systems
  You can create the following applications:

  - CENTUM integration
    This is an application for exchanging data with the CENTUM system.
  - CI Server integration
    This is an application for exchanging data with CI Server. In SCSU1, you can create an application for gas flow calculation in accordance with the specifications of American Gas Association.
  - Subsystem communication
    This is an application for exchanging data with the SCS and the subsystem connected via Modbus. It supports Modbus communications using serial communication module and Ethernet communication module.

    You can create an application that collects events and data from the ProSafe-SLS in serial communication.
  - Safety subsystem communication
    This is an application for safely exchanging data between SCS and subsystem devices. It supports communication using fire and gas communication module.
  - Modbus slave communication
    It is an application that exchanges information between an external device (a Modus master) and the SCS that are connected through Modbus communication. It is compatible for the Modbus communication that exchanges information via serial communication module and Ethernet communication module.
  - DNP3 communication application
    This is an application for communicating between the DNP3 master and SCSU1 connected via DNP3.

Overview of SCS software configuration

SCS is equipped with an application logic execution function for detecting dangerous situations and executing control to prevent or mitigate such situations and an external connection function inclusive of functions for integration with CENTUM which is the production control

system of Yokogawa Electric. Note that these functions exchange data with a station on the control bus via a control bus communication function which serves as an interface. In particular, when data is being written into the application logic execution function, the memory inside the SCS is protected with various functions for ensuring safety with such as security levels.

SENG: Station that handles engineering and maintenance of SCS
HIS: Station that executes operation and monitoring of CENTUM
FCS: Control station of CENTUM
PRM: Plant Resource Manager

Figure A3-1 Overview of SCS function configuration

Application logic execution function

This function monitors the safety condition of the plant and makes the process shift to the safety state on detecting any hazards. It mainly performs the following processing.

- Receiving Analog Input (AI)/Digital Input (DI) data from the field
- Execution of user-defined application logic
- Sending Analog Output (AO)/Digital Output (DO) data to the field
- Inter-SCS safety communication
- SCS link transmission
- Communication data I/O (subsystem communication function, safety subsystem communication function)
- Self-diagnosis

Application logic

An SCS executes application logic written in the IEC 61131-3 program language. The application logic is defined by the user using Multi Language Editor and downloaded to the SCS.

An SCS supports the following three languages of IEC 61131-3:

- Function Block Diagram (FBD)
- Ladder Diagram (LD)
- Structured Text (ST)

TIP

The application logic execution function explained here is not simply a name for a function that handles execution of the application logic; rather, it is a generic name for all the functions explained above, including the actual execution of the application logic. In this manual, this term is used in the following explanation as well.

SEE ALSO

For more information about Structured Text (ST), refer to:

2., “Structured text” in POU Reference Manual (IM 32P03B20-01EN)

For more information about Function Block Diagram (FBD), Ladder Diagram (LD), refer to:

1., “Overview of POU” in POU Reference Manual (IM 32P03B20-01EN)

External communication function

This is a function for exchanging information with external systems connected to an SCS and it does not influence the application logic execution function. Main operations are as follows:

- Diagnostic information collection function
- SOER function
- CENTUM Integration Function
- CI Server integration function (SCSP3, SCSP2, SCSP1, and SCSU1)
- Modbus slave communication function
- PRM-supported HART On-demand Communication
- DNP3 communication function (SCSU1 only)

A3.1 SCS hardware configuration

This section describes the hardware configurations for SCSs that support SIL 3 and SIL 2.

SCS hardware configuration that supports SIL 3

If the safety control unit is S2SC70D or S2SC70S (SCSP3), these three following methods are available to connect the I/O node to the SCSP3:

- N-IO nodes only connection
- Safety node units only connection
- Combined connection of N-IO nodes and safety node units

If the safety control unit is SSC60D or SSC60S (SCSP2), only the safety node unit can be connected.

The following table shows the main hardware names used in SCS that supports SIL 3.

Table A3.1-1 Main hardware names used in SCS that supports SIL 3

Name	Description	Note
SCU	Safety control unit	SSC60D/SSC60S (*1) and S2SC70D/ S2SC70S
SNU	Safety node unit	SNB10D
PSM	Power supply module	SPW481, SPW482, and SPW484. Always redundant.
CPU	Processor module (CPU module)	SCP461 (SSC60 only), SCP461 S2, and S2CP471
SEC401/ SEC402	ESB bus coupler module	Used when SNU and N-IO nodes are used. Installed in slots 7 and 8 of SCU. Always redundant.
SSB401	ESB bus interface module	Always redundant
SNT401/ SNT411	Optical ESB Bus Repeater Master Module	Always redundant
SNT501/ SNT511	Optical ESB Bus Repeater Slave Module	Always redundant
S2EN402/ S2EN404	N-ESB bus coupler module	Used when N-IO node is used. Installed in SCU. Always redundant.
FIO	FIO I/O module	Analog I/O module that supports SIL 3, digital I/O module that supports SIL 3, and communication module
N-IO node	Node for installing N-IO	Configured with node interface unit and N-IO I/O unit.
PSU	Power supply unit for N-IO	S2PW503 and S2PW504. Always redundant.
S2EN501	N-ESB bus module	Used when N-IO node is used. Installed in N-IO node. Always redundant.
N-IO	N-IO I/O module	Universal type I/O module
ESB bus	Bus to connect SCU and SNU	-
N-ESB bus	Bus to connect SCU and N-IO node	-
Optical ESB bus	Bus to connect SCU, SNU, and N-IO node	-

*1: N-IO node is not connectable.

N-IO node only connection

The following configuration are used when connecting only the N-IO nodes to the safety control unit.

When connecting the safety control unit and N-IO nodes by using the N-ESB bus, the S2EN402/S2EN404 is mounted to the safety control unit, and S2EN501 to the N-IO node. When connecting the safety control unit and N-IO node by using the optical ESB bus, the SEC401/SEC402 is mounted to the safety control unit, and S2EN501 to the N-IO node.

The connection between N-IO nodes must be connected with the N-ESB bus or the optical ESB bus.

The following figure shows an example of configuration with N-IO nodes-only connection.

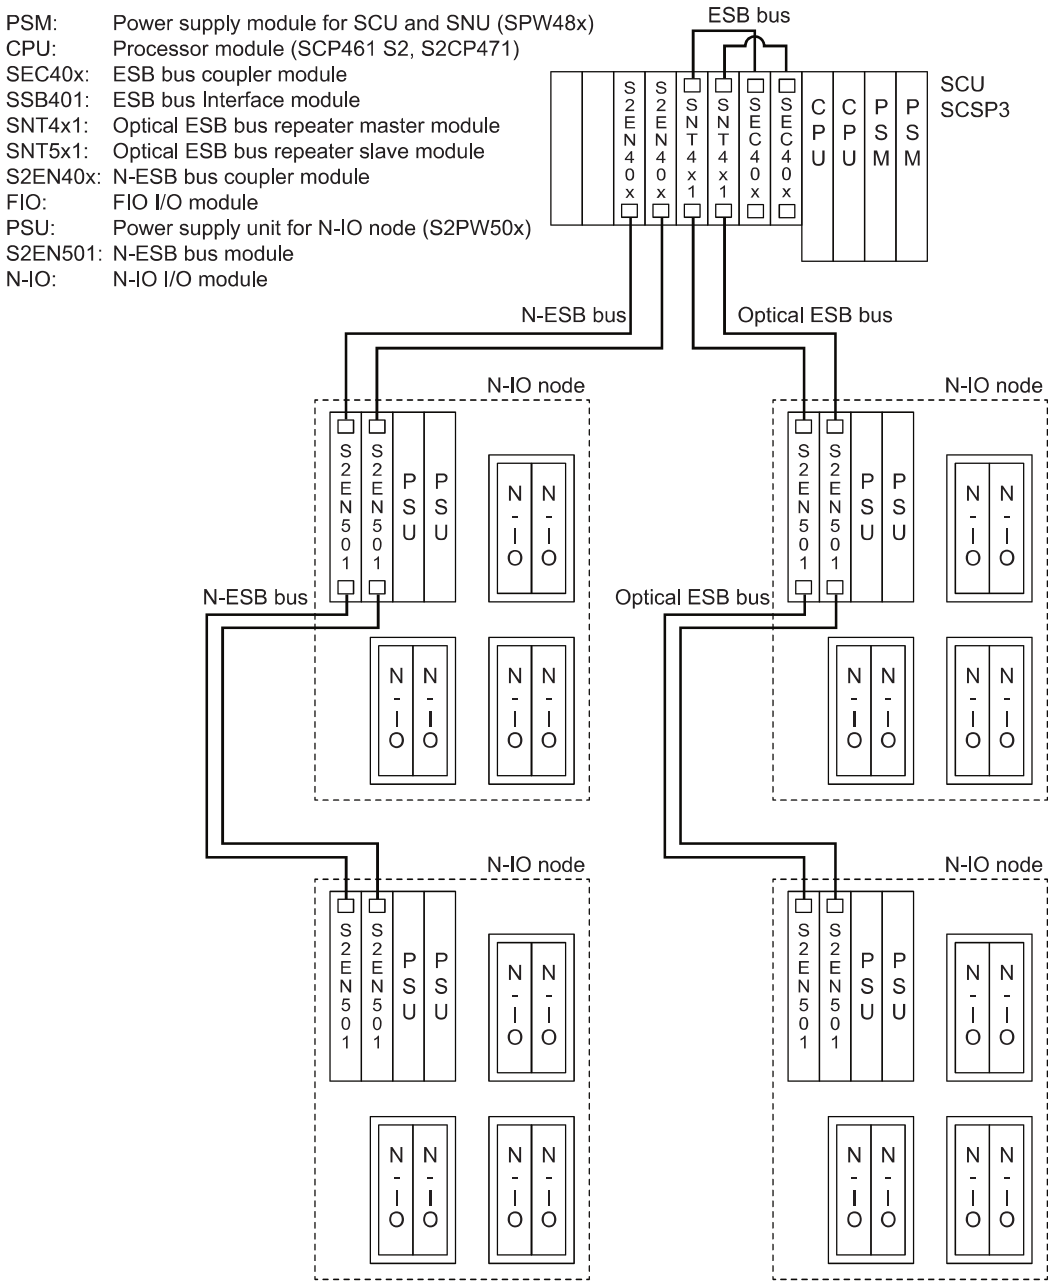

Figure A3.1-1 Configuration example of an N-IO node-only connection

Safety node unit only connection

The following configuration are used when connecting only the safety node units to the safety control unit.

When connecting the safety control unit and safety node unit by using the ESB bus, the SEC401/SEC402 is mounted to the safety control unit, and SSB401 to the safety node unit. When connecting the safety control unit and safety node unit by using the optical ESB bus, the SEC401/SEC402 and SNT401/SNT411 is mounted to the safety control unit, and SNT501/SNT511 and SSB401 to the safety node unit.

The connection between the safety node units must be connected with an ESB bus, or an optical ESB bus through SNT401/SNT411 and SNT501/SNT511.

The following figure shows a configuration example of a safety node units-only connection.

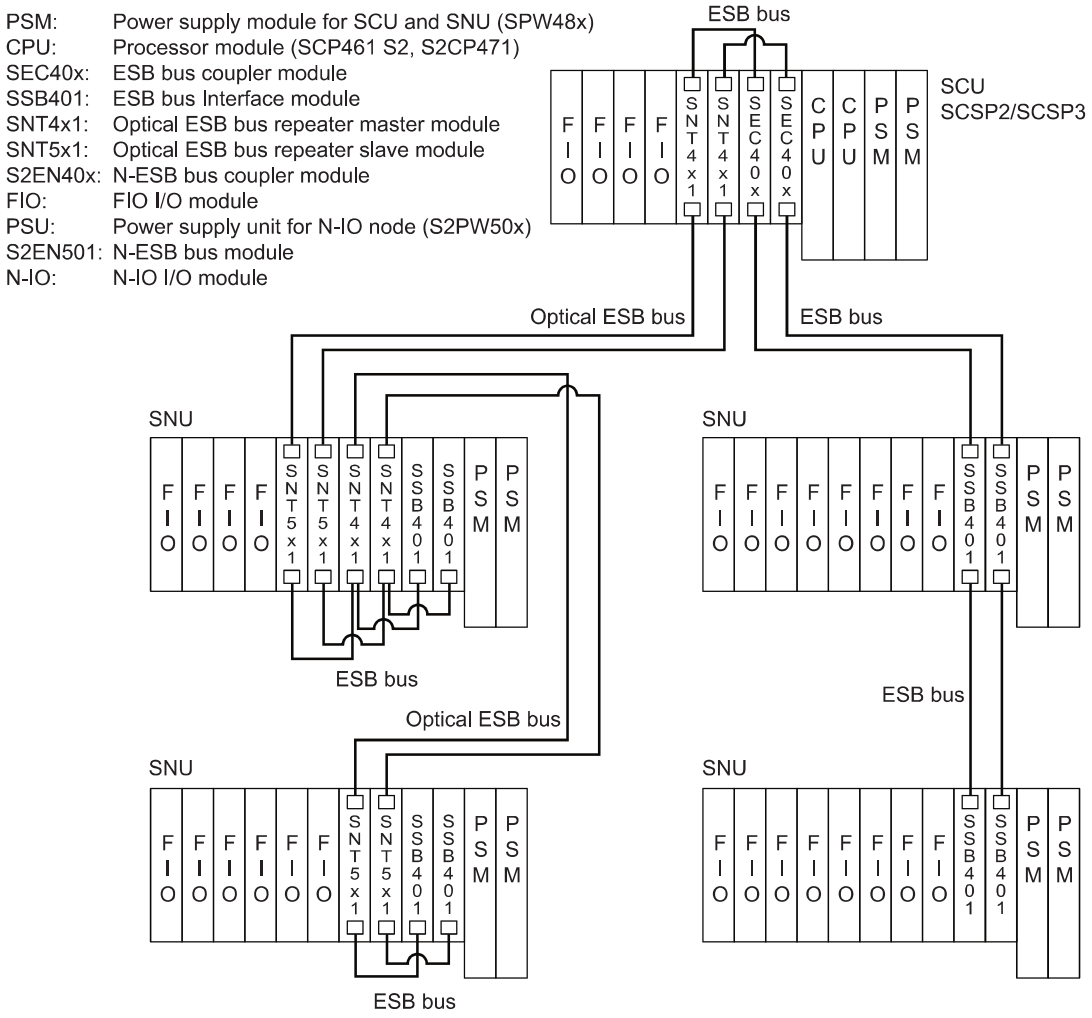

Figure A3.1-2 Configuration example of a safety node units-only connection

Combined connection of N-IO node and safety node unit

N-IO nodes and safety node units can be connected to a single safety control unit. To use both nodes together, you can connect the N-IO node and safety node unit, or separate them.

- Connecting N-IO nodes and safety node units together
  When connecting the safety control unit together with the safety node units and N-IO nodes, connect with the following configuration.

When connecting the safety control unit and N-IO node using the optical ESB bus, the SEC401/SEC402 and SNT401/SNT411 are mounted to the safety control unit, and S2EN501 to the N-IO node.

N-IO node and safety node unit are connected through an optical ESB bus. SNT501/ SNT511 and SSB401 are installed to the safety node unit.

The following figure shows a configuration example of an N-IO node and safety node unit connection.

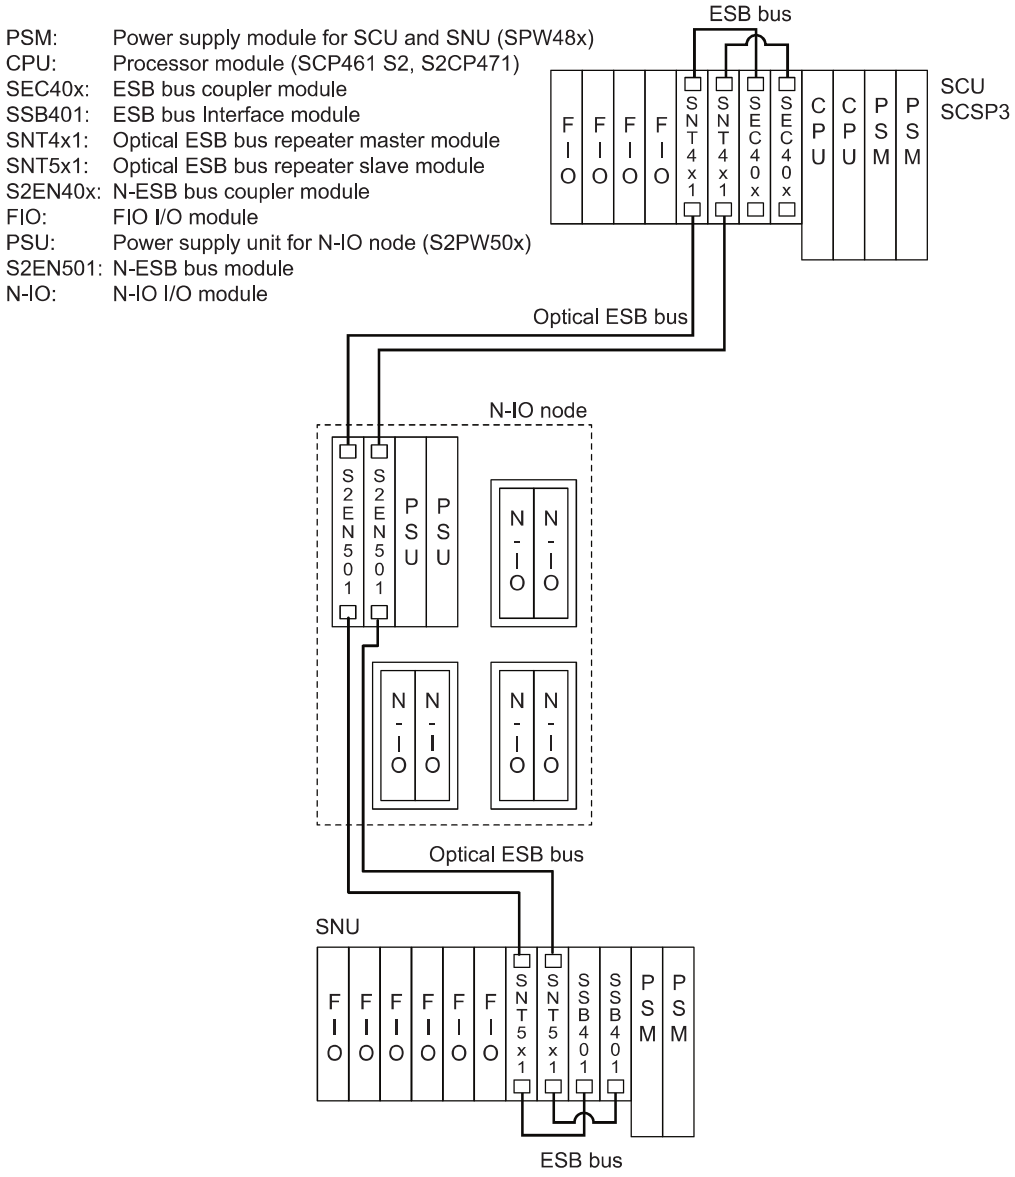

Figure A3.1-3 Configuration example of an N-IO node and safety node unit connection

- Separating N-IO nodes and safety node units, and connecting them together
  When N-IO nodes and safety node units are separated from each other, and they are connected with the safety control unit, the N-IO nodes-only connection and the safety node units-only connection are combined.

  The following figure shows a configuration example when N-IO node and safety node unit are separated and connected together.

PSM: Power supply module for SCU and SNU (SPW48x)
CPU: Processor module (SCP461 S2, S2CP471)
SEC40x: ESB bus coupler module
SSB401: ESB bus Interface module
SNT4x1: Optical ESB bus repeater master module
SNT5x1: Optical ESB bus repeater slave module
S2EN40x: N-ESB bus coupler module
FIO: FIO I/O module
PSU: Power supply unit for N-IO node (S2PW50x)
S2EN501: N-ESB bus module
N-IO: N-IO I/O module

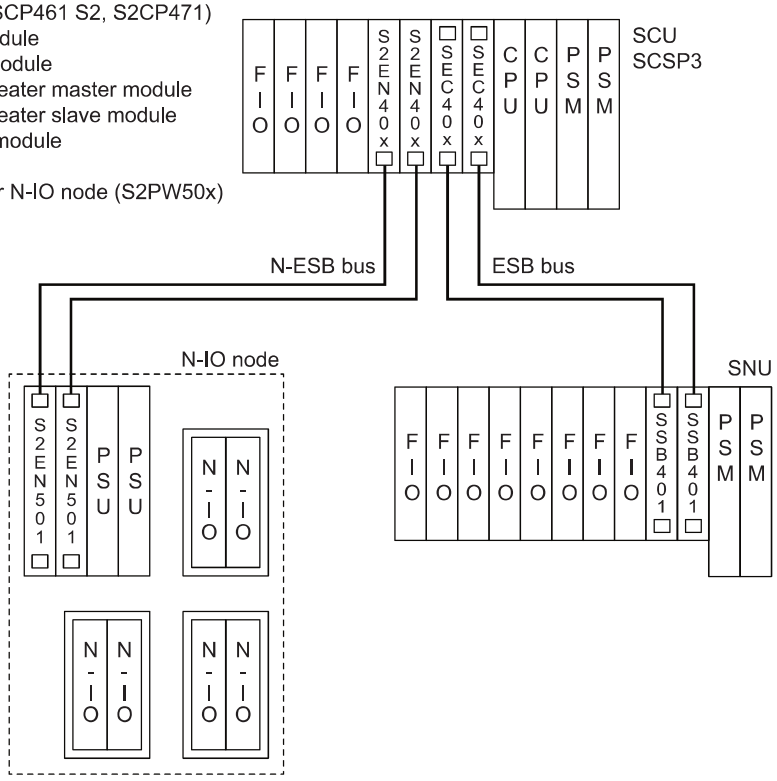

Figure A3.1-4 Configuration example when N-IO node and safety node unit are separated and connected together

SCS hardware configuration that supports SIL 2

If the safety control unit is L1SC70D or L1SC70S (SCSL2), only the safety node unit can be connected.

The following table shows the main hardware names used in SCS that supports SIL 2.

Table A3.1-2 Main hardware names used in SCS that supports SIL 2

Name	Description	Note
SCU	Safety control unit	L1SC70D/L1SC70S
SNU	Safety node unit	L1NB10D
PSM	Power supply module	L1PW481, L1PW482, and L1PW484. Always redundant.
CPU	Processor module (CPU module)	L1CP471
L1EC401/ L1EC402	ESB bus coupler module	Used when SNU is used. Installed in slots 7 and 8 of SCU. Always redundant.
L1SB401	ESB bus interface module	Always redundant
L1NT401/ L1NT411	Optical ESB Bus Repeater Master Module	Always redundant
L1NT501/ L1NT511	Optical ESB Bus Repeater Slave Module	Always redundant
FIO	FIO I/O module	Analog I/O module that supports SIL 2, digital I/O module that supports SIL 2, and communication module
ESB bus	Bus to connect SCU and SNU	-

Continues on the next page

Table A3.1-2 Main hardware names used in SCS that supports SIL 2 (Table continued)

Name	Description	Note
Optical ESB bus	Bus to connect SCU and SNU	-

Safety node unit only connection

The following configuration is used when connecting only the safety node units to the safety control unit.

When connecting the safety control unit and safety node unit by using the ESB bus, the L1EC401/L1EC402 is mounted to the safety control unit, and L1SB401 to the safety node unit. When connecting the safety control unit and safety node unit by using the optical ESB bus, the L1EC401/L1EC402 and L1NT401/L1NT411 are mounted to the safety control unit, and L1NT501/L1NT511 and L1SB401 to the safety node unit.

The connection between the safety node units must be connected with an ESB bus, or an optical ESB bus through L1NT401/L1NT411 and L1NT501/L1NT511.

The following figure shows a configuration example of a safety node units-only connection.

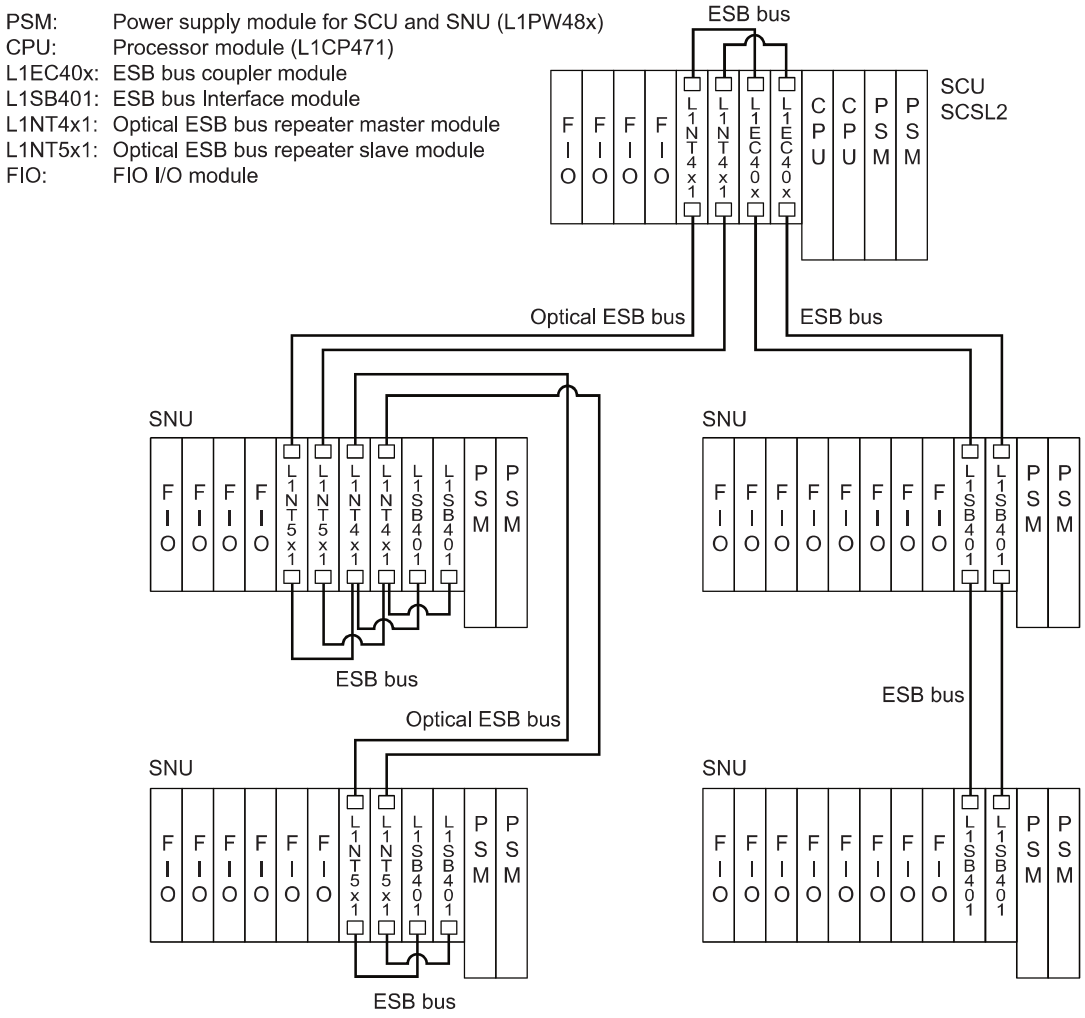

Figure A3.1-5 Configuration example of a safety node units-only connection

A3.2 RAS (Reliability, Availability, Serviceability) functions of SCS

This section explains functions related to reliability, availability and serviceability of the SCS (hereinafter referred to as RAS in this manual). Moreover, it is a function that implements safety. The function includes the ability to shift to a safe state in a fast and reliable manner when an error occurs in the plant or system.

The RAS functions of the SCS are as follows:

- Operating mode
- Security level
- Diagnostic management function, diagnostic information messages
- Operation during start, and operation during error
- Dual redundancy

SEE ALSO For more information about the functions for checking the SCS status, refer to:

H., “Monitoring the SCS status” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about the operations upon SCS error occurrence and recovery procedures, refer to:

G2., “Operations and recovery procedures during the SCS error occurrence” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Positioning of RAS function

RAS stands for Reliability, Availability and Serviceability, and is an important index when evaluating the system performance. Reliability means robustness against error occurrence, availability means shortness of downtime and serviceability means ease of repair at failure.

Functional relation of software

The RAS function diagnoses whether hardware and software are running normally and handles maintenance of them if any errors are detected. Since this function is able to shut the system down and change the SCS status as required, it is one of the most essential SCS functions.

Relationship with other hardware

The RAS function collects hardware error information concerning the I/O modules and other components in the station. The RAS function organizes hardware error information and executes pre-defined safety operations accordingly, such as shutting down. Error information is sent to the SENG and HIS as diagnostic information messages. The SCS saves diagnostic information generated internally. And the information can be referenced from SENG. You can delete saved diagnostic information messages from SENG.

The figure below shows how the RAS function of the SCS is positioned.

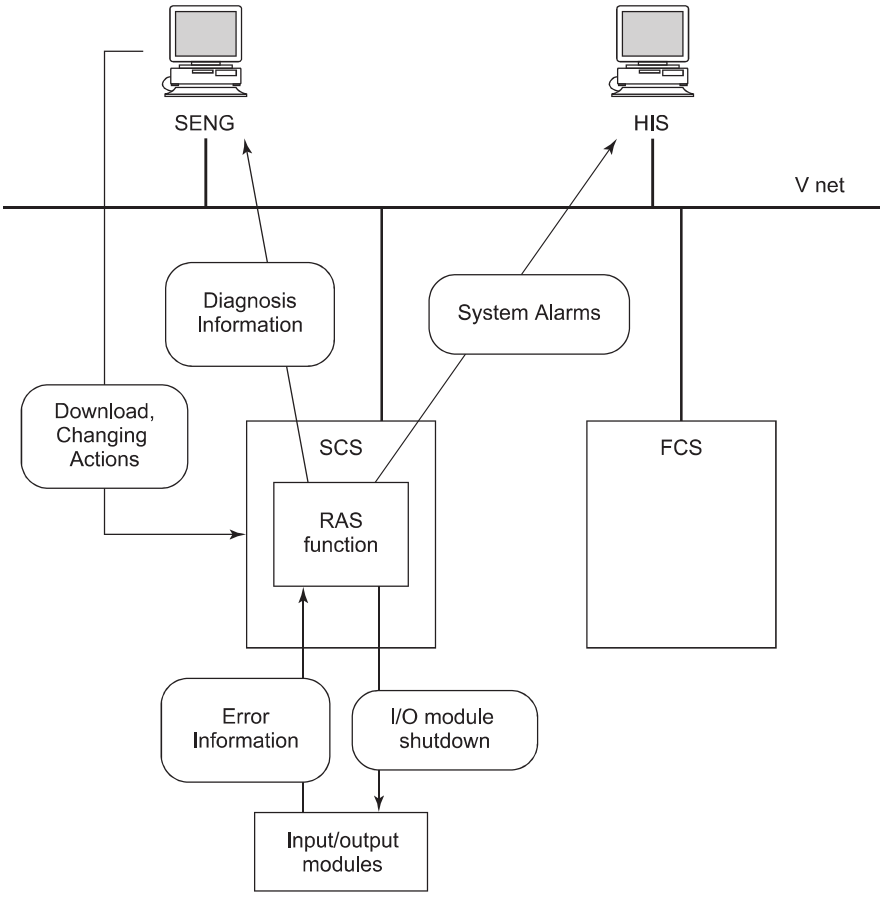

Figure A3.2-1 Positioning of RAS function

A3.2.1 SCS operating mode

The operating mode indicates the operation status of an SCS. Operations of the functions that are implemented by the system program of the SCS are determined by the operating mode. The operating mode is outlined as follows:

- The operating mode indicates the overall operating status of SCS, not the status of individual output modules.
- The operating mode indicates the status of a single SCS, regardless of whether the CPU configuration of the SCS is single or dual-redundant.
- For an SCS with dual-redundant CPU, the operating mode remains the same before and after a control right switchover of the CPU.

There are five SCS operating modes: Stop mode, Loading mode, Initial mode, Waiting mode, and Running mode

The following figure shows the transitions between operating modes. Note that it is possible to shift to the Stop mode from all other modes, but the arrows indicating these shifts are omitted for the sake of clarity.

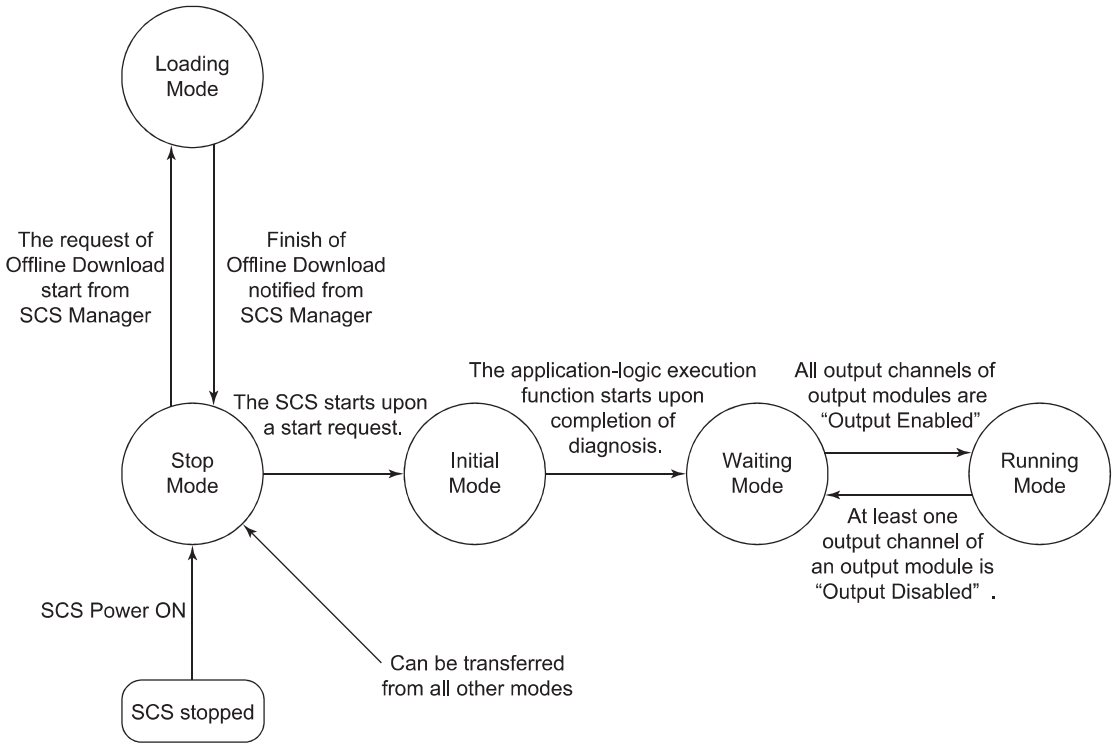

Figure A3.2.1-1 Transitions between operating modes

Stop mode (stopped status)

This is the initial state of the SCS.

Loading mode (during offline download)

In this mode, program and database are being downloaded from the SCS Manager to the SCS.

Initial mode (initializing status)

In this mode, the SCS is initializing databases, processing the diagnostic at startup, and starting the I/O modules as follows:

- Input modules
  If started successfully, input values are set to applicable input variables. If the startup of any module has failed, an error is recognized for the module.
- Output modules
  The outputs of all channels remain disabled after the startup is completed, so that the output values from the application logic will not be sent to the field immediately.
- Subsystem communication modules
  Receives only the input from subsystems while having an output that is invalid.
- Fire and gas communication modules
  If the startup process is successfully completed, fire and gas communication modules receive only the input from subsystems. If the startup process ends in an error, the SCS handles the fire and gas communication modules as erroneous.

Waiting mode (waiting for output enable request)

Application logic is periodically executed on each scan period. However, the output channel will not output the application logic value if the status is set to "Output Disable". The waiting mode status can be checked in the SCS State Management window and the LED display of the CPU module.

When "Output enable operation" is performed, the outputs on the normal channels of output modules are enabled. If you execute the "Output enable operation" just after starting up the SCS, the SCS also enables the output of inter-SCS safety communication, SCS link transmission and subsystem communication.

TIP

- Failure on the output channel should be removed, then perform "Output enable operation".
- Even when the channel is set to "Output Disabled", if the physical data is rewritten using the forcing function, the output value from the output channel changes.

SEE ALSO

For more information about Data value in unlocked / locked status and output disable / enable status, refer to:

A6.2, “I/O variable” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about Output enable operation, refer to:

C8., “Output enable operation” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about SCS State Management Window, refer to:

H1.2, “SCS State Management window” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Running mode (controlling status)

This mode indicates that the SCS is running normally. All output channels of output modules are outputting the output values from the application logic. The Running mode status can be checked with the SCS State Management Window and LED display of the CPU module.

Output status monitoring

All output channels of output modules are monitored. If any of the channels becomes Output Disable status due to a failure in the corresponding module or in the output channel itself, or after adding new channels during online modification, the SCS will change its operating mode to the Waiting mode. The operating mode changes to the Running mode when the cause of the channel failure is removed, the output enable operation is completed and all output channels are placed in the Output Enable status.

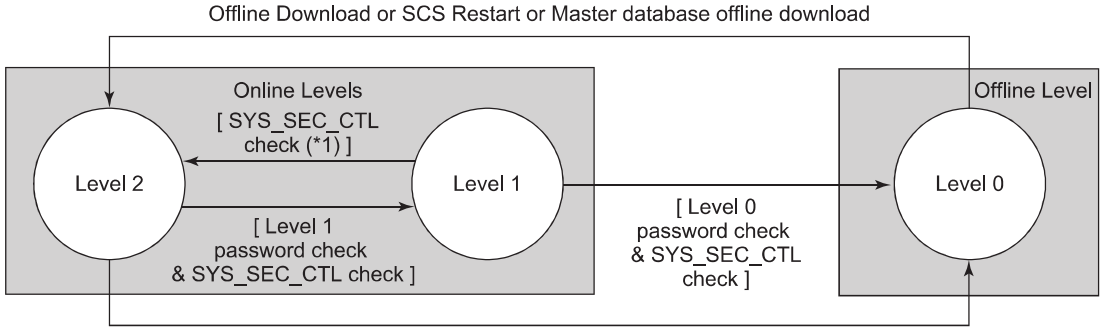
Checking of operation mode

The operating mode of SCS can be checked with the following methods.

- It is possible to check that the operating mode is either the Waiting or Running mode with the SCS State Management window of the SCS Maintenance Support Tool, the SCS Status Display view of HIS and the LED display of a CPU module.
- If the operating mode is either the Waiting or Running mode, the operating mode can be referenced from the application logic as well.

Influence on operating mode

Engineering and occurrence of errors can affect the operating mode as follows.



- The operating mode is not affected even if a subsystem communication error, safety subsystem communication error, or communication module error occurs.
- Occurrence of errors in SCS link transmission has no influence on the operating mode.
- If output modules/channels are added via online change download, the added modules/channels are started from the Output Disable status. If the operation mode was Running mode previously, it changes to Waiting mode. Perform the output enable operation.
- If channels in the Output Disable status or output modules that include such channels are deleted via online changes and there are no longer any channels in the Output Disable status in SCS, the operating mode shifts from Waiting mode to Running mode.
- If a single output module is changed to dual redundant configuration by online change download, IOM download is executed in order to initialize the modules. The outputs of the target modules become disabled after downloading. Since some channels are in the Output Disable status, the operating mode of SCS shifts to the Waiting mode. Perform the output enable operation after the output modules recover to normal.
- It is possible to perform the output enable operation regardless of the status of communication modules.
- It is possible to perform the output enable operation even if the status of communication with sub-systems is BAD. In this case, only outputs that are ready to communicate will start.

A3.2.2 Security level of SCS

The security level of SCS indicates the level of protection against erroneous writing to the memory in SCS from the connected stations or devices. An overview of SCS security level is as follows:

- One SCS has one security level.
- The security level can be confirmed from LED on the CPU module and the SCS State Management window of SCS Maintenance Support Tool or Status Display View of HIS.
- SCS limits changes made from the outside according to security level.
- Security level can be referred to by applicable logic.
- Security level can be changed by an authorized user with the password using the SCS Manager.
- Using the system function block (SYS_SEC_CTL) makes it possible to control whether or not to allow security level change operations from an SENG with an external hardware switch or similar.
- Security level can be changed under the following conditions:
  - The SCS is either in the Waiting or Running mode, AND
  - The SYS_SEC_CTL is set to allow security level changes or is not used.

The following figure illustrates the transition of states of the security level.

*1: It is allowed to reset the security level from Level 1 to Level 2 via the RST input in the SYS_SECURE block, regardless of the security level change enable/disable status of SYS_SEC_CTL.

Figure A3.2.2-1 Transition of security level status

Definition of each security level

There are two classifications of levels; online level and offline level. The Online level is used when SCS is in normal operation. The Offline level is used when SCS is not in normal operation.

Online level

The Online Level is a security level to be used when normal operation is performed in SCS. The SCS itself provides security of the Online Level by controlling access to the memory from the outside.

The Online Level is separated into two levels according to limits of functions which can be used.

Table A3.2.2-1 Online level

Level	Description
Level 2	The highest security level. SCS is usually operated at this security level.
Level 1	A temporary security level used by engineers or authorized users for maintenance of equipment or changing applications online

Offline level

The Offline Level is a security level to be used when a regular operation is not performed in SCS. This is displayed as "Level 0" on the LED of SCS or the SCS State Management window of SENG. In the Offline Level, SCS does not limit access to SCS from the outside. However, information which was used at test may be stored in SCS databases depending on operations performed by those tools.

IMPORTANT

To restore an SCS to Online Level from Offline Level, restart the SCS or do offline download. This ensures that the system returns to the security level for normal operation.

Security level at the start of SCS

The security level is Level 2 when SCS starts normally.

A3.2.3 Diagnosis for hardware

The SCS carries out diagnosis at the following timing to check whether various types of hardware including I/O modules are in the normal state:

- At the start of the hardware
- At specified periodical intervals during operation

This section describes the HKU function in the CPU module, and the cabinet status monitoring function in the N-IO node.

HKU (House Keeping Unit)

The HKU function in the CPU module monitors the operation environment of the CPU module. An error in the CPU operating environment is notified to the user via diagnostic information messages and status display window. The following items are monitored by the HKU function.

- Fan status in the safety control unit
- Surrounding temperature of the safety control unit
- Battery temperature

Cabinet status monitoring

The N-ESB bus module of N-IO node monitors the operating environment of the cabinet. An error in the operating environment of the cabinet is notified to the user via diagnostic information messages and status display window.

Temperature monitoring

The SCS monitors the surrounding temperature of the N-ESB module, as well as the upper limit and lower limit value in the hardware. It monitors whether the temperature exceeds the prescribed value or not.

Power supply diagnosis

The SCS monitors the status of the power supply unit (PSU) connected to the N-ESB module unit. The following are the methods in diagnosing a power supply:

- PSU output stop diagnosis
  The SCS monitors the output voltage in redundant PSUs. It is judged as an error if output in either of the PSUs stops.
- Output over-voltage diagnosis
  The SCS monitors the output voltage of the PSUs, as well as the upper limit and lower limit value in the hardware. It monitors whether the output voltage exceeds the prescribed value or not. It is judged as an error if it exceeds the maximum value.

Input monitoring from external devices

By inputting a single point of discrete signal from an external device, which can detect power supply and fan abnormalities, in an external alarm input of the base plate, errors from the external device can be notified.

The safety control unit outputs the diagnostic information message according to the discrete signal that is inputted from the external device.

Because this function is interference-free, it cannot be used for safety logic.

A3.3 Dual-redundancy in the SCS

ProSafe-RS supports dual-redundant configurations of SCS CPU modules and input/output modules. With the dual-redundant configuration, the continuous controllability and operating efficiency can be improved. Moreover, with dual-redundantly configured hardware, the continuity of plant safety monitoring will be guaranteed by switching the control rights when an error occurs in the SCS hardware.

A3.3.1 Redundant configuration in SCS

In SCS, redundant configuration can be selected for the CPU module and I/O modules. The control bus, power supply module, ESB bus, ESB bus interface module, optical ESB bus repeater module, N-ESB bus, N-ESB bus module, and F-SB bus are always in redundant configurations.

CPU module

- The CPU module on the standby side performs the same control processing as the control side even while it is in the standby status. For this reason, it is possible to take over outputting data immediately after the control right is switched. Moreover, the operating mode of the SCS does not change.
- Only the CPU on the control side accesses the hardware composing the SCS and the CPU on the standby side always sets the equivalent value as the processing result. Therefore, the CPU modules on both sides always perform processing using the same data.
- In redundant configuration, if the CPU module on the standby side is not in the STBY status and the control right cannot be switched, the same operation as single configuration CPU module is performed.
- SOE data related to discrete inputs might be lost when the control right is switched between the CPU modules.
- With the CPU module of SCSL2 and the CPU module of SCSP2, the data loaded with the previous scan may be used instead of updating the data with the value from the input module when performing a scan immediately after a control right switchover of the CPU. Also note that data loaded from 1 or 2 scans earlier may be used with subsystem communication modules.
- With the CPU module of SCSP3, the data loaded with the previous scan may be used instead of updating the data with the value from the input module or fire and gas communication module when performing a scan immediately after a control right switchover of the CPU. Also note that data loaded from 1 or 2 scans earlier may be used with subsystem communication modules.

FIO I/O modules

Redundant configuration is possible in the FIO node(*1) by mounting the same type of FIO I/O module to two adjacent slots. In the case of redundant configuration, one side becomes the control side and the other becomes the standby side. Switching of the control right is performed by input/output modules. The switching has no influence on the application logic.

*1: An odd-numbered slot and the even-numbered slot obtained by adding 1 to the odd slot number

- It is not allowed to have redundant configuration across two nodes.
- SOE data related to discrete inputs might be lost when the control right is switched between the input modules even though the frequency is low.
- A HART communication error may occur when the control right is switched between analog input/output modules that support HART communication.

Table A3.3.1-1 Operation of redundant AIO/DIO modules

AIO/DIO module	Redundant operation
Analog input module Digital input module	The input data of the input module on the control side is stored in the input variable.

Continues on the next page

Table A3.3.1-1 Operation of redundant AIO/DIO modules (Table continued)

AIO/DIO module	Redundant operation
Analog output module Digital output module	The SCS outputs the same value for output modules on both the control and standby sides. Only the output module on the control side outputs signals to the field. If an error occurs on the module on the control side, the control right is switched and outputting is continued

SEE ALSO For more information about implementing dual-redundant subsystem communication, refer to:

D1.2, "Dual-redundant communication" in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

For more information about implementing dual-redundant Modbus slave communication, refer to:

"■ Redundancy of Modbus communication" in F4., "Precautions for engineering" in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

■ NIO I/O modules

Redundant configuration is possible in the N-IO node by mounting the same type of N-IO I/O module to two adjacent slots. In the case of redundant configuration, one side becomes the control side and the other becomes the standby side. Switching of the control right is performed by input/output modules. The switching has no influence on the application logic.

- SOE data related to discrete inputs might be lost when the control right is switched between the input modules even though the frequency is low.
- A HART communication error may occur when the control right is switched between analog input/output modules that support HART communication.

Table A3.3.1-2 Redundant operation in N-IO I/O modules

Signal type	Redundant operation
AI/DI	The input data of the input module on the control side is stored in the input variable.
AO/DO	The SCS outputs the same value for output modules on both the control and standby sides. Only the output module on the control side outputs signals to the field. If an error occurs on the module on the control side, the control right is switched and outputting is continued

■ Optical ESB bus repeater module

The optical ESB bus repeater modules are always used in a redundant configuration.

■ Power supply module

A redundant power supply module is installed on each of CPU nodes, I/O nodes, and N-IO nodes of the SCS. The SCS monitors the status of the power supply at regular intervals and, if an error occurs, it notifies the user about the error via the SCS State Management window of the SENG, the Status Display view of the HIS, and diagnostic information messages. If one of the two power supplies mounted on the CPU node has generated an error, it notifies two diagnostic information messages; one corresponding to the error of the power supply module on the CPU node and the other corresponding to the error of the power supply module on node 1.

■ ESB bus and ESB bus interface module

The ESB bus is redundant. The two ESB buses are connected to their corresponding ESB bus interface modules. The following operations also apply when optical ESB bus repeater devices are present along the communication route.

- Normally, redundant ESB buses are used in an alternating fashion.
- If an error occurs in either ESB bus interface module, the user is notified of the error with a diagnostic information message. If both buses fail, the error is treated as a node failure.
- If an error occurs in one ESB bus or ESB bus interface module, the SCS continues communication by using only the other ESB bus that is normal.
- An erroneous bus is monitored for normal recovery at regular intervals.
- Errors in communication with all I/O nodes, except CPU node, are judged to be ESB bus error.

N-ESB bus and N-ESB bus module

The ESB bus has redundant configuration. Each N-ESB bus module is connected to N-ESB bus, respectively.

- Normally, redundant N-ESB buses are used in an alternating fashion.
- If an error occurs on either N-ESB bus module, the error is notified to the user via a diagnostic information message. If both buses fail, the error is treated as a node failure.
- If an error occurs in either N-ESB bus or N-ESB bus module, the SCS continues communication using only the normal ESB bus on the other side.
- An erroneous N-ESB bus is monitored for normal recovery at regular intervals.

F-SB bus

The F-SB bus has redundant configuration.

- The F-SB bus is normally used at the same time on both sides.
- If an error occurs in either F-SB bus, the SCS continues communication using only the normal ESB bus on the other side.
- An erroneous F-SB bus is monitored for normal recovery at regular intervals.

Vnet/IP communication

Vnet/IP is redundant. Independent subnets using bus 1 and bus 2 comprise redundant buses.

Normally, bus 1 is used for control communication. If a communication error occurs on bus 1, bus 2 is used to perform control communication.

A3.3.2 CPU redundant status

The availability of an SCS can be improved by making CPUs redundant. Each of the redundant CPUs can be in either control or standby states, which are unique to the CPU.

CPU status

In order to show the status of a redundant configuration, it is necessary to indicate the status of each CPU separately. The operating status of the CPU is called the CPU status.

- The CPU status indicates the operating status of the CPU.
- The processing of the SCS references the CPU status as necessary. The user can check the CPU status via the CPU's LED, the SCS State Management window of the SENG, and the Status Display view of HIS.
- If an error occurs in the standby CPU, the FAIL status is notified to the application logic via a system block.

The figure below illustrates the CPU status shift. Note that in order to explain the CPU status, the operating modes it can shift to the Initial mode are called "CTRL" and "STBY." These indicate whether the CPU has the control right and are specific to the redundant status, i.e., not related to the operating mode.

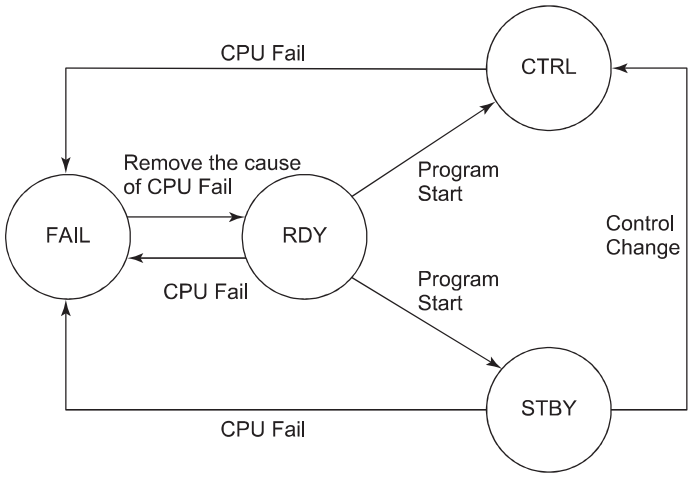


Figure A3.3.2-1 CPU status

FAIL (CPU stopped)

The power is supplied to the CPU, but the software is not running in this status.

RDY (CPU initializing status)

The system program is being set in the main memory in this status.

CTRL (control status)

The system program runs inside the CPU and the CPU has the right to access input/output modules in this status.

STBY (standby status)

The system program runs inside the CPU but the CPU does not have the right to access input/output modules in this status.

CPU status shift in redundant configuration

The figure below illustrates each CPU status and how it may shift in redundant configuration. The thick arrows from (a) to (d) indicate the flow from the startup to normal operation in redundant configuration. Note that the figure below does not represent the status by the mounting positions of the CPUs. Even if the states of the two CPUs are switched, the indication in the figure shows them in the same status.

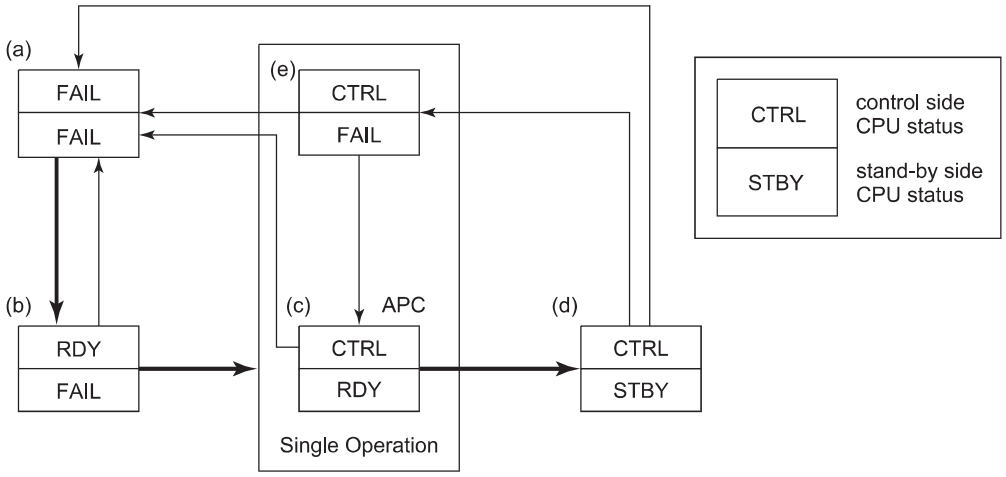

Figure A3.3.2-2 States at redundant configuration

Table A3.3.2-1 CPU status

Status	Description
(a)	CPUs on the both sides stopped.
(b)	The controlling CPU starts up and sets programs and databases in the main memory.
(c) (*1)	The controlling CPU obtains the control right and starts up the standby CPU. Upon launching, the standby CPU copies the image of the main memory of the controlling CPU into its main memory (this status is displayed as "APC" and not the same as status (e)). The controlling CPU executes the user application.
(d)	Both the controlling and standby CPUs operate normally in redundant configuration. This status is called the redundant control status.
(e) (*1)	In this status, the standby CPU is stopped in redundant configuration, or the controlling CPU is stopped and the control right is switched. The same operation as in single configuration is performed.

*1: Single operating status.

The CPU shifts to each status in the following manner.

Table A3.3.2-2 Conditions of CPU status shift

Before	After	Shifting conditions
(a)	(b)	• The power supply to the SCS is started. • SCS offline download is completed. • The system is restarted.
(b)	(c)	The controlling CPU started normally.
(c)	(d)	APC of the standby CPU is completed.
(d)	(e)	The control right is switched due to a failure of the controlling CPU hardware or the standby CPU failed.
(e)	(c)	The standby CPU is replaced or a CPU recovered from transient failure.
(b)	(a)	An error occurred in the self-diagnosis at startup.

Continues on the next page

Table A3.3.2-2 Conditions of CPU status shift (Table continued)

Before	After	Shifting conditions
(c)	(a)	A fatal error occurred while operating in single CPU operation.
(d)	(a)	Power failure occurred in the SCS (including momentary power failure).
(e)	(a)	A fatal error occurred while operating in single CPU operation.

APC status

The APC status refers to the status where the data in the CPU memory is being copied from the control side to the standby side.

The APC status can be checked by the LED on the CPU, the SCS Status Display window of the SENG or the Status Display view on the HIS. The start and end of the APC status are notified via a diagnostic information message.

A4. Outline of the safety system generation function

This section gives an overview of the tools used to configure and maintain a safety system.

It also describes the different types of applications that can be created by using ProSafe-RS.

Recreating an SCS project with R4 and selecting the engineering method

If an SCS project has been recreated, you must select the engineering method based on the presence of a safety I/O list.

Guidelines for selecting an engineering method

The engineering method of the project should be selected based on one of the following guidelines:

If a safety I/O list that is consistent with the SCS project exists, or if you are engineering by using a newly created safety I/O list, the I/O list engineering method is recommended. Select an I/O list engineering when you use iDefine as an engineering tool.

Also, when performing engineering for safety subsystem communication, select I/O list engineering.

If a safety I/O list that is consistent with the SCS project does not exist, or if you are using a SCS project that was created by using an SCS with RS original engineering, choose the RS original engineering method instead.

TIP If you upgrade to version R4, the metered license is applied regardless of the engineering method that you select.

Editor and tools that are used for I/O list engineering

The following table shows the editors and tools used when performing I/O list engineering.

You can start the SCS Manager from the System Structure Navigator in AD Organizer.

Table A4-1 Editor and tools that are used in I/O list engineering

Category	Operation	Means to operate editors and tools SCS Manager/AD Organizer	Editor or tool name	Remarks
Safety application	Safety logic definition	SCS Manager	Multi-Language Editor (*1)	-
	Variables and parameters definition	SCS Manager	Dictionary View (*1)	I/O variables are automatically created from the safety I/O list. Instances of subsystem communication I/O FB, PROFINET communication input FB, and fire and gas communication input FB are automatically generated from the safety communication I/O list. Internal variables and FB instances can be defined by iDefine.
I/O	I/O list definition	AD Organizer	Safety I/O Editor Safety Communication I/O Editor	The following information is generated: • Dictionary View • I/O Wiring View • I/O Parameter Builder • Communication I/O Builder
	Node/IOM detailed definition	AD Organizer	IOM Definition Editor	The information for the following is created: • I/O Wiring View • I/O Parameter Builder

*1: iDefine can be used as well.

Safety application definition

Safety applications are created with tools and builders called from the AD Organizer and the SCS Manager.

When using AD Suite to perform I/O list engineering, you need to use the editors in AD Organizer to set the items instead of using I/O Wiring View, I/O Parameter Builder, and Communication I/O Builder.

If you select I/O list engineering and use iDefine, you can create the application logic by using iDefine based on the ProSafe-RS I/O file that was exported from AD Organizer. The ProSafe-RS I/O file is a file generated for engineering with iDefine based on the safety I/O list, safety communication I/O list, and IOM definition.

*1 : In the case of I/O list engineering, you can reflect the safety I/O list, safety communication I/O list, and IOM definition to the SCS Manager builder by running the reflection process through RS Generation Manager. If you run the reflection process on the engineering data that was created by using iDefine through RS Generation Manager, the application data can be reflected to the Multi-Language Editor and SCS.

*2 : AD Organizer exports the data that was created from the safety I/O list, safety communication I/O list, and IOM definition to iDefine.

*3 : AD Organizer imports the engineering data that was created by using iDefine.

Figure A4-1 Overview of safety application definition

AD Organizer

AD Organizer is installed in the SENG computer. You can perform the ProSafe-RS engineering by using AD Organizer. AD Organizer comes with some built-in engineering tools, and SCS Manager is one of them.

Safety I/O Editor

This is an engineering tool that can be used from AD Organizer.

The tool is used to create safety I/O lists based on plant information data and import them as engineering data.

It is also used to define variables that are related to the safety I/O. You specify the SCS node and IOM applicable to the P&ID tag and the associated connection information based on the information that is displayed in the Safety I/O Editor.

With this editor, you can export a file containing data for engineering with iDefine.

Safety Communication I/O Editor

This is an engineering tool that can be used from AD Organizer.

This tool is used to create safety communication I/O lists based on plant information data and import them as engineering data.

It is also used to define variables that are related to the safety communication I/O. You specify the SCS node and IOM applicable to the P&ID tag and the associated connection information based on the information that is displayed in Safety Communication I/O Editor.

With this editor, you can export a file containing data for engineering with iDefine.

IOM Definition Editor

This is an engineering tool that can be started from AD Organizer.

In the IOM Definition Editor, a list of nodes and I/O modules are displayed with their properties.

You can use the IOM Definition Editor to define the I/O module configuration and set the properties of nodes and I/O modules. If I/O module assignment information is not defined in the safety I/O list or safety communication I/O list, you can define the assignment of I/O modules to nodes by using IOM Definition Editor.

ADMDB

This is the server database that stores all the engineering data that is included in the AD Server. The revision history of the engineering data and the hardware configuration information are also stored in this database.

The AD Server manages the engineering data.

Generation Manager

For SCS projects that are created with I/O list engineering, Generation Manager reflects the information of the safety I/O lists, safety communication I/O lists, and I/O module configuration and builds SCS projects.

Hardware Architecture View

- Set the configuration name.
- Define the IP address of the SCS.

Link Architecture View

- Configuring the security settings of the SCS project.
- Defining the POU.(*1)
- Adding variable groups.
- Starting the Multi-Language Editor to edit the POU that you have defined.

*1: POU: Program Organization Unit It is a generic term for the programs, function blocks (FB), and functions (FU) that are written with the function block diagram (FBD) and ladder diagram (LD)

SCS Project Properties

Defining Project properties including station type, domain number, and station number of SCS.

Designating location of the integrated CENTUM project folder, in the case of CENTUM Integration Configuration.

SCS Constants Builder

Setting SCS common constants and time synchronization method.

Dictionary View

If you select the RS original engineering method, the Dictionary View is used to set the parameters of FUs and FBs and define project variables. If you select the I/O list engineering method, the variables that were defined by using AD Organizer and iDefine are read-only in Dictionary View.

Multi-Language Editor

Edit the POUs for the LBD, LD, and ST.

POUs that were defined by using iDefine are read-only in Multi-Language Editor.

Binding List View

Binding variables from the producer to the consumer of Inter-SCS safety communication.

SCS Link Transmission Builder

Defining SCS link transmission safety communication and SCS global switch communication.

I/O Wiring View

In the SCS project where the RS original engineering method is selected, the I/O Wiring View is used to define the following:

- Analog I/O module, digital I/O module, universal type I/O module (these three types of modules are collectively called "AIO/DIO modules"), and communication module
- Wiring between I/O module channels and I/O variables

If you select I/O list engineering, this builder is read-only.

I/O Parameter Builder

In the SCS project where the RS original engineering method is selected, I/O Parameter Builder is used to configure the node, module, and channel parameters, including the settings for the operation when a fault is detected in an I/O module or channel, and to define SOER collection through DI/DO.

If you select I/O list engineering, this builder is read-only.

Communication I/O Builder

For SCS projects for which I/O list engineering is selected, this builder becomes read-only. Use Safety Communication I/O Editor when you assign communication I/O data for safety subsystem communication and perform wiring of communication I/O variables. The contents of Safety Communication I/O Editor will be reflected in this builder by running a reflection from AD Organizer.

CENTUM integration application definition

The following figure shows the outline of CENTUM integration application definition and the associated builders.

These builders are opened from the engineering launcher of the SCS Manager.

- Tag Name Builder
  This builder defines tag names for FBs and variables which can be used for CENTUM Integration Configuration, and also defines annunciator messages.

  Defining a tag name results in the creation of a mapping block for CENTUM Integration Configuration.

  When engineering by using iDefine, you can also define the tag names for FBs and variables by using iDefine. Use the reflection process from Generation Manager to reflect the definitions in Tag Name Builder. Tag names that were defined by iDefine are read-only in Tag Name Builder.
- Alarm Priority Builder
  This builder defines alarm priority. The condition of alarm activation is set to each alarm priority as in CENTUM.
- Alarm Processing Table Builder
  The Alarm Processing Table Builder is used to import the ‘Alarm Processing Table defined in CENTUM’ to SCS project.

  This table determines the priority of process alarms that are generated from mapping blocks when integrating with CENTUM.

When engineering by using iDefine, you can also configure the tag names in iDefine. The tag names are read-only except for configured tools.

In a CENTUM integration structure, the application of ProSafe-RS needs to be defined with those builders. Furthermore, engineering of CENTUM including SCS definition and tag list generation needs to be executed on CENTUM ENG. This allows HIS to access SCS data with a tag name and to display annunciator messages.

The following figure provides an overview of CENTUM Integration Application Definition.

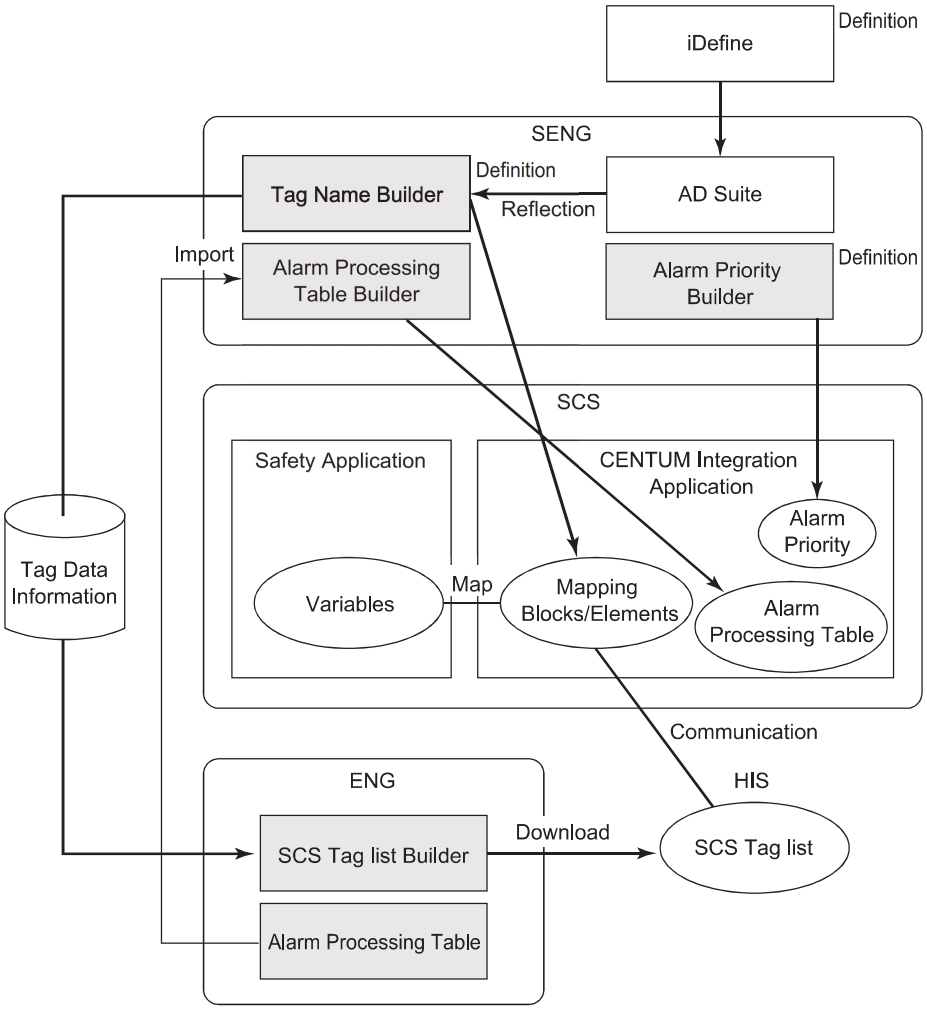

Figure A4-2 Outline of CENTUM Integration Application Definition

Defining applications that use communication modules

In ProSafe-RS, you can create an application that exchanges data with other system through a communication module. Modbus slave communication, Modbus subsystem communication, and safety subsystem communication are supported. Safety subsystem communication can be used with SCSP3 only. In addition, you can create DNP3 communication applications in SCSU1. Modbus slave communication and Modbus subsystem communication are interference-free functions. Safety communication is included in safety subsystem communication.

The following builder is used for Modbus slave communication:

- Modbus Address Builder
  It defines the Modbus device address.

The following figure shows the outline of the definitions of Modbus slave communication application.

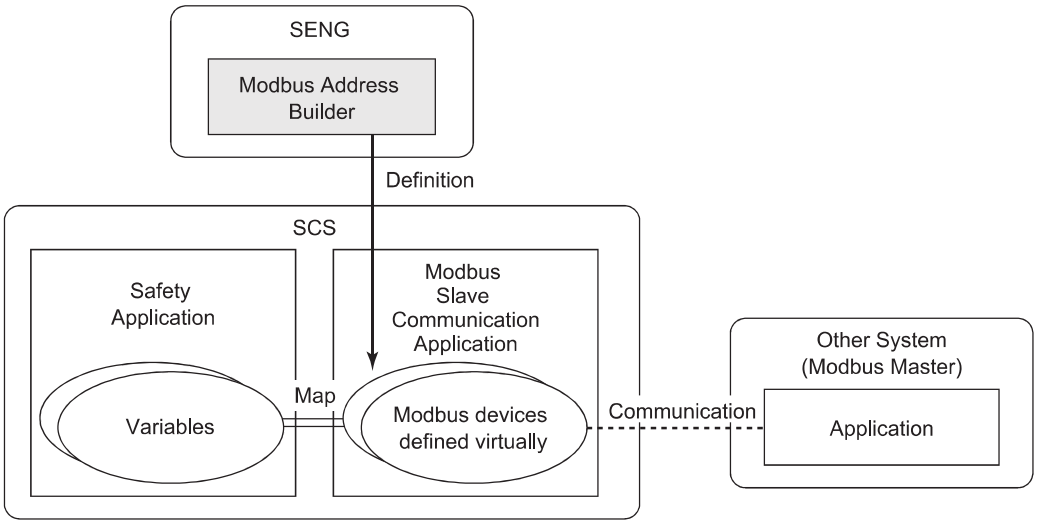

Figure A4-3 Outline of Modbus slave communication application definition

The following builder or editor is used for subsystem communication:

- Communication I/O Builder (for RS original engineering)
- Safety Communication I/O Editor of AD Organizer (for I/O list engineering)
  It defines the communication data, and allocates the communication I/O FB there.

The following two types of subsystem communication are supported:

- Using the serial communication module, you can create an application for subsystem communication between SCS and Modbus PLC. By creating an application for subsystem communication between SCS and ProSafe-SLS, you can acquire events and data of ProSafe-SLS.
- Using Ethernet communication module, you can create an application for the subsystem communication between the SCS and Modbus/TCP PLC.

The following editor is used for fire and gas communication:

- Safety Communication I/O Editor of AD Organizer
  Define communication data and assign the PROFINET communication I/O FB and fire and gas communication FB to the communication data.

  Using fire and gas communication modules, you can create an application for safety subsystem communication between the SCS and fire and gas devices.

The following builder is used to define DNP3 communication applications:

- DNP3 Communication Builder
  This builder enables SCS to act as a DNP3 slave station and associates DNP3 data with application logic variables.

The following figure shows the outline of the DNP3 communication application definitions.

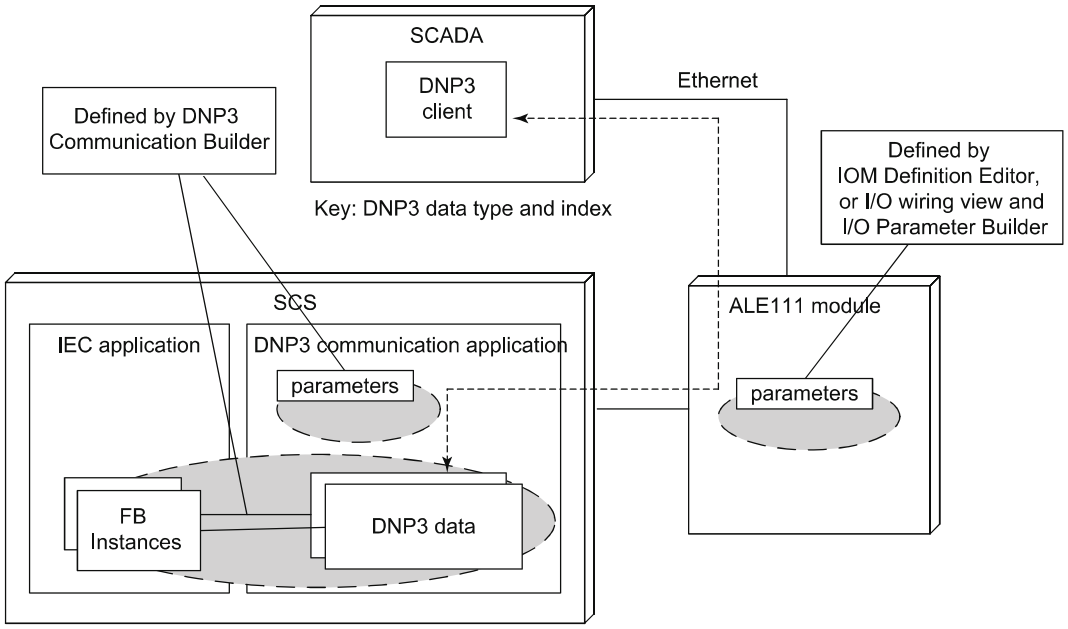

Figure A4-4 Outline of DNP3 communication application definition

CI Server integration application definition

The following describes the builder and outline of the CI Server integration application definitions. CI Server integration is an interference-free function.

In CI Server integration, you can define I/O modules and create function blocks in addition to using the following builders and tools:

- Domain Properties Setting Tool
  It selects the operating mode of Vnet/IP-Upstream.
- Message Cache Tool
  A group is defined when the network configuration of Vnet/IP-Upstream is in the narrow-band mode.
- Tag Name Builder
  You can enter tag name, and other information to the data to be handled in CI Server.

  When engineering by using iDefine, you can also define the tag names for FBs and variables by using iDefine. Use the reflection process from Generation Manager to reflect the definitions in Tag Name Builder. Tag names that were configured by using iDefine are read-only in Tag Name Builder.

Engineering tools

The following describes the tools that are used after you have created a ProSafe-RS application:

Integrity Analyzer

The Integrity Analyzer is used to analyze the safety of existing created application logics. It detects unauthorized FB /FU as the safety function, and outputs results of analyzing on screen or on the analysis report.

Cross Reference Analyzer

It shows, on screen or on the analysis report, the difference between the application previously downloaded (which runs currently on SCS) and the application to be downloaded soon as well as the extent of impact in case of downloading. The Cross Reference Analyzer is for limiting the scope of retesting when application logic is modified.

- ## Self-Documentation function

  This is for printing user applications. The entire definitions of an SCS project or any parts can be selected as a printed item.

- ## Project Attribute Tool

  This tool can be used to display the attribute of an SCS project.

- ## Test Project Creation Tool

  This tool can be used to copy a project that is running at a plant site and create a project for test purpose.

- ## Import/Export function

  Import or export functions can be used to import or export SCS project data. Therefore, these data can be used for test functions or for reusing applications.

- ## Project Comparing Tool

  This tool can be used to detect the difference between two specified SCS projects and to display and print the result.

- ## Version Control Tool

  This is for controlling the version history of an SCS project to support the project updates by users.

  By using Version Control Tool, you can save (check-in) the project data of an SCS project at a certain point upon adding a version number and restore (check-out) project data of a certain version. If you are performing I/O list engineering, start this tool from AD Organizer. If you start it from the Start menu, the data of AD Suite cannot be handled by the tool.

- ## Master Database Restoring Function

  This function is used to restore the contents of the master database as the work database. Use this function to discard changes made to the work database and use the master database as the data subject to engineering (work database). If you are performing I/O list engineering, start this tool from AD Organizer. If you start it from the Start menu, the data of AD Suite cannot be handled by the tool.

- ## Database Validity Check Tool

  The Database Validity Check Tool is used to check the integrity of the database in the work database and master database of SCS project, and SCS database in SCS. The master database can be repaired if the master database has lost validity due to such as an error that has occurred during online change download. This repair function of the tool repairs the master database by replacing it with the work database.

- ## SCS Information

  This function is used to display and print SCS project usage conditions such as POUs used within the SCS and the number of variables. The number of licenses available is displayed separately for SIL 2 and SIL 3. This function can also be used to check the database revisions in the SCS project, number of project I/O licenses and their usage. You need to build an SCS project before using this function.

A4.1 Window components common to builders

Multiple builders are used for engineering applications that will run on the SCS. This section describes the base window layout common to all the builders, taking the SCS Constants Builder window as an example.

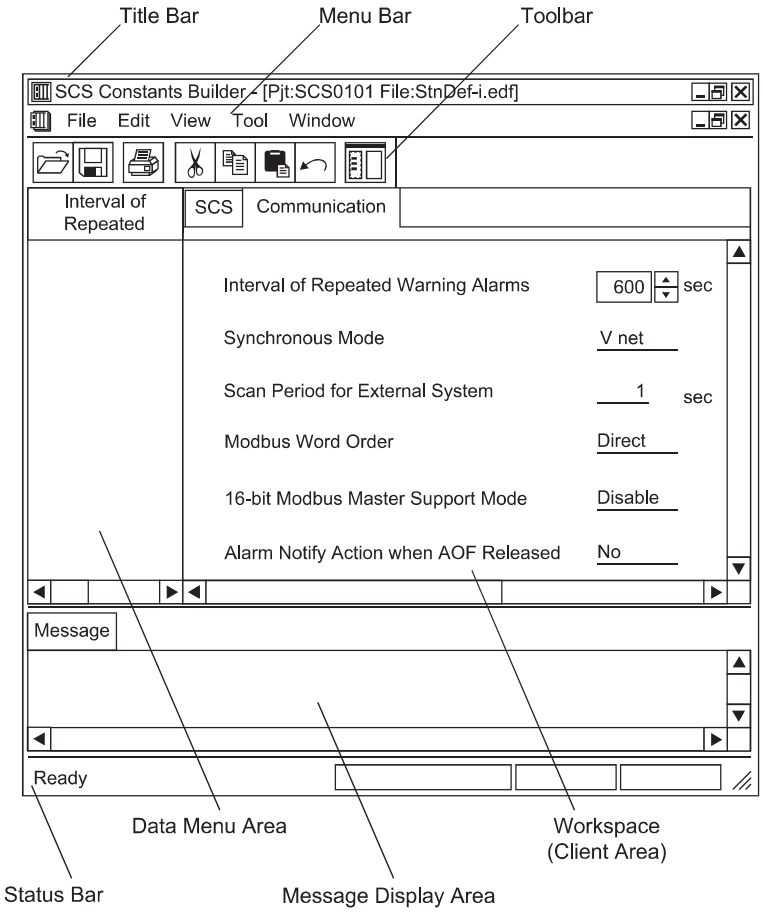

Figure A4.1-1 Window of SCS Constants Builder

Title bar

The title bar displays project name, file name, etc.

Menu bar

The menu bar contains the [Edit], [Tools] and other menus. The menu structure of the menu bar differs depending on the builder; the menu bar used on most builders is as follows.

File menu

Table A4.1-1 File menu

Menu item	Description
Open	Opens a file created by this builder and saved with a specific name (SVA file)
Close	Closes the window
Save	Saves the data displayed in the window in a file
Save As (*1)	Saves the data displayed in the window in a file with a specific name

Continues on the next page

Table A4.1-1 File menu (Table continued)

Menu item		Description
External File ->	Import	Imports the contents saved in a file with a specific format to the currently opened window
	Export	Exports the contents of the currently opened window into a file with the specific format
Properties		Displays a dialog box for displaying and editing information related to the window properties
Print		Launches Document Generator for printing the data displayed in the window
Status Label -> (*2)	Custom Import	Imports the alarm status texts modified on the CENTUM builders.
	Delete	Deletes the alarm status texts imported from the CENTUM builders.
Latest File		Shows a list of files saved with specific names (SVA files) that were opened in the past
Exit SCS Constants Builder (*3)		Closes SCS Constants Builder

*1: On the SCS Constants Builder, you need to save the settings separately on each tab sheet.
*2: Only available on SCS Constants Builder
*3: Builder name is displayed as the affix of the menu name.

TIP If there is no document window, only [Open], [Latest File] and [Exit SCS Constants Builder] are displayed.

Edit menu

Table A4.1-2 Edit menu

Menu item	Description
Undo	Cancels the previously performed edit operation
Cut	Deletes the selected character string and copies it onto the clipboard
Copy	Copies the selected character string onto the clipboard
Paste	Inserts the character string stored in the clipboard
Clear	Clears the character string of the selected field
Find	Displays a dialog box to search for a specified character string set in the builder
Replace	Displays a dialog box to search and replace a specified character string set in the builder

View menu

Table A4.1-3 View menu

Menu item	Description
Toolbar	Determines whether or not to display the toolbar
Status Bar	Determines whether or not to display the status bar
Data Menu Area	Determines whether or not to display the data menu area
Message Display Area	Specifies whether or not to show the message display area

Tools menu

Table A4.1-4 Tools menu

Menu item	Description
Environment Setting...	Starts Builder Environment Tool for setting the operation environment commonly used for builders

Window menu

Table A4.1-5 Window menu

Menu item	Description
Cascade	Arranges document windows so that they overlap
Tile Horizontally	Arranges document windows horizontally
Tile Vertically	Arranges document windows vertically
Arrange Icons	Arranges minimized document windows

Toolbar

The toolbar contains icons representing frequently used functions in the menu bar.

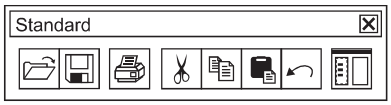

Figure A4.1-2 Toolbar

Table A4.1-6 Functions assigned to the toolbar

Button	Name	Assigned function
	Open	Same as [Open] of the [File] menu
	Save	Same as [Save] of the [File] menu
	Print	Same as [Print] of the [File] menu
	Cut	Same as [Cut] of the [Edit] menu
	Copy	Same as [Copy] of the [Edit] menu
	Paste	Same as [Paste] of the [Edit] menu
	Undo	Same as [Undo] of the [Edit] menu
	Display/Hide Data Menu	Same as [Data Menu Area] of the [View] menu

Data menu area

The data menu area has the following functions.

- Displays input guidelines for the selected data (e.g., meaning of an input item and data input range).
- If data has options, the area displays the option menus and allows selecting an option. In that case, it is also possible to select an option by pressing a key.

- Displays tree view and changes the workspace tabs (excepts for SCS Constants Builder).

Message display area

The message display area displays the execution result of saving files, etc.

A4.2 Types of downloading

The downloading functions transfer SCS execution data which contain application logics to an SCS.

The SCS database is saved as the master database in the SENG and the same data as in the SCS is maintained at all times. There is no function to upload the SCS execution data to the SENG because the SCS execution data is saved in the SENG as the master database.

Overview and types of downloading

Offline download

This function downloads a database generated from application logic created in the SENG. During download, the functions running on the SCS stop and resume operation after the completion of downloading.

Online change download

This function downloads only a portion of database generated from application logic, created in the SENG, that have been updated since the last download. The functions running on the SCS keep operating during the download as well. Note that online change download may not be possible depending on the content of the updates.

Master database offline download

This function downloads the execution data that was active in an SCS again after replacing a CPU module. The SCS database saved in the master database on the SENG is downloaded. This download is performed when replacing hardware. In case of a redundant CPU module, this download is not required if only one module is replaced.

TIP

Close the I/O lock window when performing the following operations.
Otherwise, an error message will be displayed and the downloading will be stopped.

- Online change downloading
- Offline downloading
- Master database offline downloading

IOM download

This function downloads the execution data that was active in an input/output module to a new input/output module after replacing it. The data of the input/output module (part of the SCS database) saved in the master database on the SENG is downloaded.

This download can only be performed when replacing hardware of input/output modules.

Save and download operation marks

The operation marks set on the HIS can be saved in SENG.

The saved operation marks can be downloaded to the SCS.

SEE ALSO

For more information about saving and downloading operation marks, refer to:

B7.1, “Engineering on the SENG side” in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

Relationship between downloading functions and databases

The destination database for saving varies depending on the type of downloading. The relationship between different types of downloading and databases is explained below.

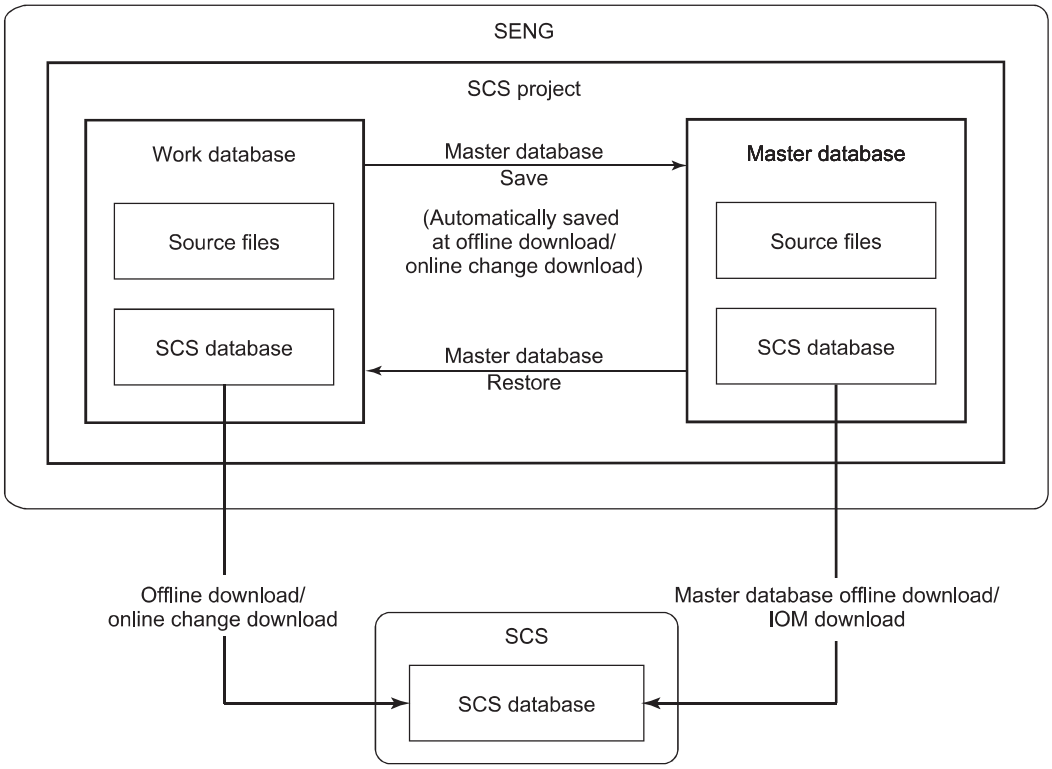

Figure A4.2-1 Relationship between downloading functions and databases

TIP

- Master Database Restoring Function is provided in order to copy the master database to the work database in case a recovery is needed. Do not operate the master database folder/files directly by using Windows explorer, or edit the master database.
- SCS projects are also registered in the ADMDB and managed by the AD Server.

Offline download

The work database generated by building is downloaded to an SCS. The master database is overwritten by the work database.

Online change download

Only differences between the work database generated by building and the master database are downloaded to an SCS. The master database is overwritten by the work database.

Master database offline download

The master database is downloaded to an SCS.

IOM download

Only data in the master database related to input/output modules is downloaded to an SCS.

Relationship between downloading functions and SCS security levels

Since the downloading functions attempt to write data to an SCS, download operations may not be allowed depending on the SCS security level. Before performing the downloading functions, it is necessary to use the SCS security level operation function and change the security level of the SCS.

The table below shows whether or not each type of download is allowed according to the security level.

Table A4.2-1 Relationship between downloading functions and SCS security levels

Security level	Offline download	Online change download	Master database offline download	IOM download	Save and Download Operation Marks
Level 2	-	-	-	Yes (only for failing input/output modules)	Yes
Level 1	-	Yes	-	Yes (only for failing input/output modules)	Yes
Level 0	Yes	Yes	Yes	Yes (only for failing input/output modules)	Yes

A5. Configuration of maintenance function

This section describes the outline of the functions used for maintenance of SCS and field devices.

Outline of functions to use for maintenance

Set SCS security level

This is for changing the SCS security level in the case of downloading the database to the SCS or forcing parameters.

I/O Lock window

This is for locking/unlocking I/O channels during maintenance, and shows the locking status of the I/O channels. When inputs or outputs are locked, it is possible to set their values.

Communication I/O Lock window

This is for locking/unlocking I/O of subsystem communication and safety subsystem communication during maintenance. It shows the locking status of the inputs/outputs. It is possible to set their values when inputs or outputs are locked.

SCS Link Transmission Lock window

During maintenance, locking or unlocking the communication data of link transmission can be performed on this window. The locking and unlocking status can also be monitored. When a communication data is locked, the value of the communication data can be changed.

Inter-SCS Communication Lock window

This is for locking or unlocking inter-SCS safety communication FBs for each SCS during maintenance and shows the locking status of the FBs. When inter-SCS safety communication FBs are locked, it is possible to set their values.

Restart SCS

This is for restarting SCS.

Master database offline download

This is for downloading the master database to SCS and restarting the SCS.

Save operation marks/Download operation marks

Operation marks specified for SCS tags on an HIS in the CENTUM integration structure are initialized and thus lost when offline download to the SCS, master database offline download or SCS restart (including when recovering from power failure) are executed. This function makes it possible to recover initialized operation marks to the status at the last saved operation.

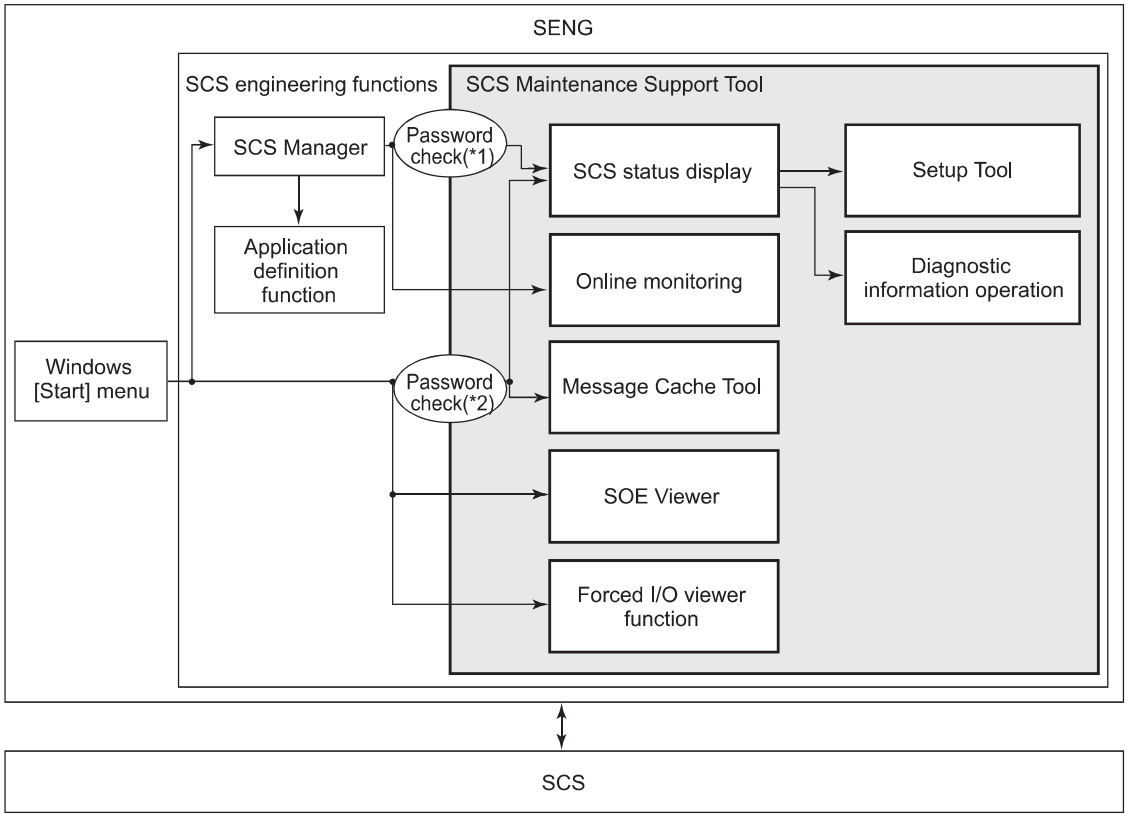
The Save Operation Marks is a function to save operation marks specified for tags on an HIS in the SENG.

The Download Operation Marks is a function to download saved operation marks to the SCS.

SEE ALSO For more information about saving/downloading operation marks, refer to:

B7.2.3, “Other builders” in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

A6. Overview of the SCS Maintenance Support Tool



SCS Maintenance Support Tool provides functions to keep track of the SCS status in ProSafe-RS maintenance. For example, SCS Maintenance Support Tool is used for when maintaining applications, analyzing cases of tripping by demand from the plant and analyzing diagnostic information generated in the SCS. SCS Maintenance Support Tool can always be used as long as the SCS is in operation regardless of its security level.

SCS Maintenance Support Tool has the following functions:

- SCS status display
- Diagnostic information operation
- Online monitoring of application logic
- Message Cache Tool
- SOE Viewer
- Forced I/O viewer function

A6.1 Relationships among functions of SCS Maintenance Support Tool

The figure below shows the relationships among the functions included in SCS Maintenance Support Tool.

*1: When the "Access Control and Operation History Management Package" is used, password checking is not performed because user authentication check is done when SCS Manager is started.
*2: When the "Access Control and Operation History Management Package" is used, password checking is not performed because user authentication check is done when the SCS Maintenance Support Tool is started.

Figure A6.1-1 Relationships among functions included in SCS Maintenance Support Tool

SCS status display

The tools for showing the SCS running status include SCS Status Overview window and SCS State Management window.

The SCS Status Overview window and the SCS State Management window are called up from the Maintenance Launcher menu of SCS Manager. The SCS Status Overview window can be launched from the [Start] menu of Windows. Note that the SCS Status Overview window and the SCS State Management window cannot be displayed at the same time. If you call up and display the SCS Status Overview window or the SCS State Management window again from the Maintenance Launcher menu of SCS Manager, the currently displayed window is closed and the newly called window appears.

If you close the SCS Status Overview window or the SCS State Management window, all windows started from that window are closed. The windows related to the SCS Status Overview window or the SCS State Management window will not be closed even if you close the SCS project in SCS Manager.

Diagnostic information operation

The Diagnostic Information window is provided as a tool for displaying diagnostic information stored in SCS.

The Diagnostic Information window is opened from the SCS Status Overview window or the SCS State Management window. The Diagnostic Information window displays diagnostic information in the range selected by the engineer in the SCS State Management window.

Online monitoring

The online monitoring function displays the operating status of the application logic in SCS. Using this function, the user can keep track of the values of variables as well as the condition statuses on FBD and LD.

Message Cache Tool

Message Cache Tool is used for checking the diagnostic information messages and SOE event acquisition conditions. Moreover, it is used to change various Message Cache Service settings and manage the collected data.

SOE Viewer

SOE Viewer is a tool to display event information held by SCS. It also displays the diagnostic information messages. The SOE Viewer is capable of displaying events and messages in chronological order, which helps you analyze messages output from the SCS.

Forced I/O Viewer function

Forced-I/O information is a collection of information such as variables that are locked in the Lock window of SENG by using the forcing function.

Forced I/O Viewer function is a function to display the forced-I/O information in a list. Forced-I/O information of multiple SCSs can be displayed collectively.

Forced I/O Viewer function consists of Forced I/O Viewer that displays the forced-I/O information and Forced I/O Viewer Setup Tool that makes the setting for collecting the forced-I/O information.

Customizing SCS Maintenance Support Tool

Setup Tool is used to customize the display and operation methods of SCS Maintenance Support Tool. Setup Tool allows you to define the settings related to fonts and operations for the SCS Status Overview window, the SCS State Management window and the Diagnostic Information window.

A6.2 Application examples at maintenance

Maintenance can be classified into two types: regularly performed maintenance and maintenance performed when an unexpected error occurs. This section describes how to use SCS Maintenance Support Tool when an unexpected error occurs, for example, in a case where the SCS diagnostic function detects errors in input/output modules.

Maintenance operations are performed by maintenance personnel in most cases. This section assumes that analysis of causes is performed by engineers and tasks of eliminating abnormality is handled by maintenance personnel, and describes the tasks involved separately.

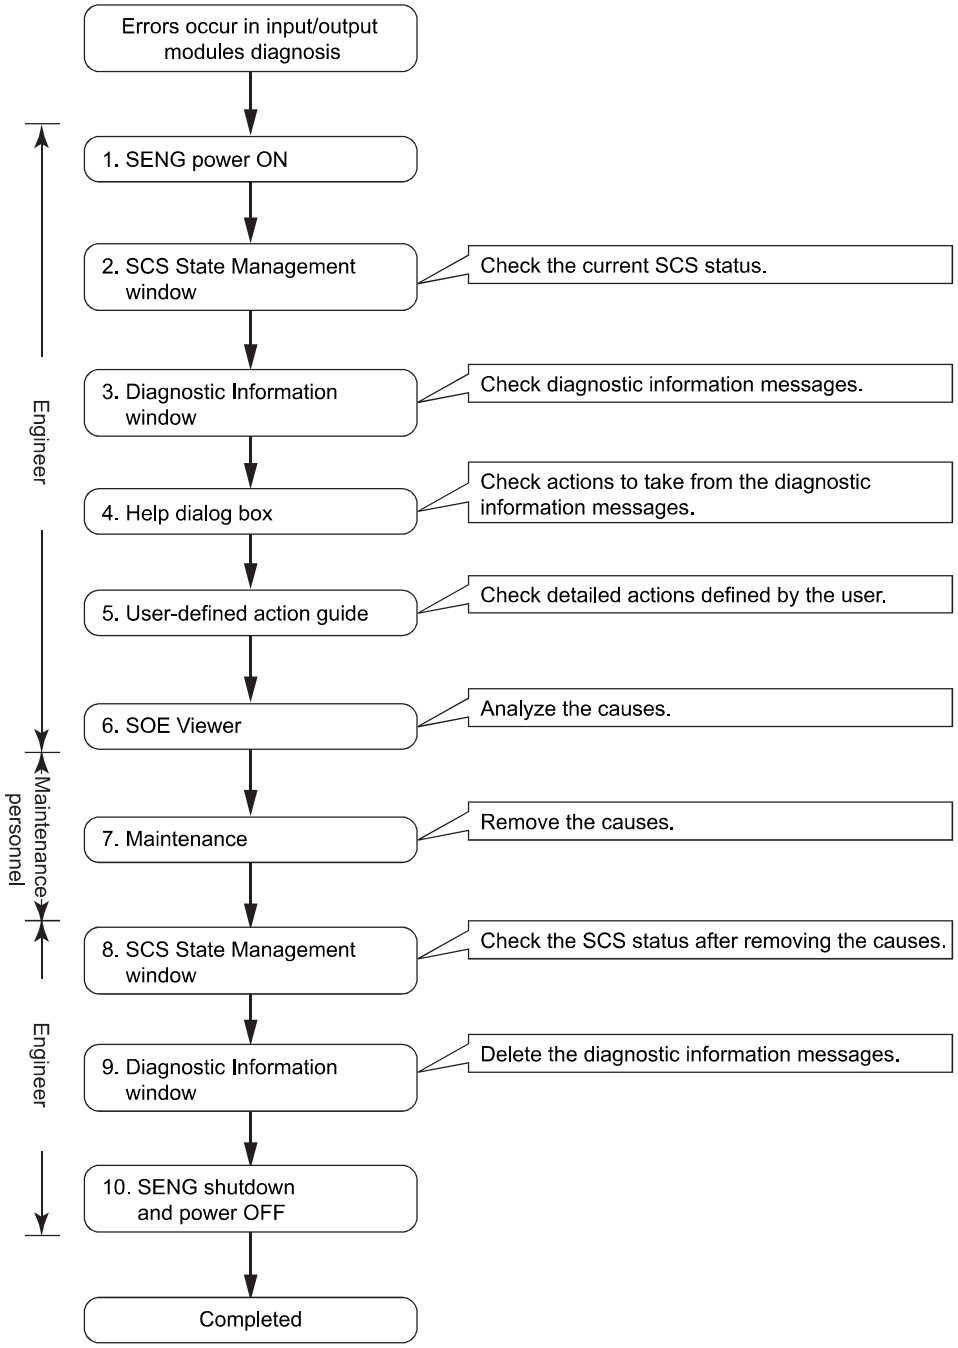


Figure A6.2-1 Workflow for maintenance operation

Step 1: SENG power on

The engineer turns ON the power supply of the SENG in order to analyze the causes of the error diagnosed.

Step 2: SCS State Management window

The engineer launches the SCS State Management window of a station that detected a diagnosed error from SCS Manager. The engineer checks the current status based on the display. The diagnostic information mark is displayed for the input/output modules on which the diagnosed errors occurred. The engineer selects those input/output modules and then displays the Diagnostic Information window in order to check the diagnostic information messages related to those input/output modules.

Step 3: Diagnostic Information window

The engineer checks the messages output by the SCS diagnostic functions. An action to be taken for a diagnostic information message can be checked with a help message displayed by double-clicking the diagnostic information message and displaying the Help dialog box. To acknowledge the diagnostic information message, click the corresponding message in the Diagnostic Information window and then click [Acknowledgement] button on the toolbar. The Acknowledgement dialog box appears. Click the [OK] button in this dialog box; the status of the diagnostic information message is placed in the acknowledged status (operation when acknowledging individually).

Step 4: Help dialog box

The Help dialog box displays help messages corresponding to message numbers. If the counter-actions measures specific to devices are available, the engineer can call the user-defined action guide from the Help dialog box to check actions to take.

Step 5: User-defined action guide

The engineer learns what actions to take against the error from the information of user-defined action guide. Note that the guide must be defined in advance by the engineers.

Step 6: SOE Viewer

The engineer identifies the causes of the error based on the diagnostic information messages and/or SOE event information at the time diagnosed errors occur. The engineer then identifies a procedure to eliminate the causes. It is possible to keep messages as records by saving them in a file.

Step 7: Maintenance

The maintenance personnel removes the causes according to the operation procedure made by the engineer.

Step 8: SCS State Management window

The engineer displays the SCS State Management window and checks that the input/output modules have recovered from the error.

Step 9: Diagnostic Information window

The engineer deletes the messages output by the SCS diagnostic functions. To delete a diagnostic information message, click the corresponding message in the Diagnostic Information window and click [Deletion] button on the toolbar; the Deletion dialog box appears. Click the [OK] button in this dialog box to delete the diagnostic information message (using the operation to delete individual message).

Step 10: SENG shutdown and power off

After analyzing the cause of the diagnosed error and removing the cause, if the SENG is not used normally, the engineer shuts the SENG down and turns the power OFF.

A6.3 Customization of the SCS Maintenance Support Tool window

The operation environment of the SCS Maintenance Support Tool window can be customized.

Items that can be customized

You can use Setup Tool to specify the following operation environment settings:

- Selecting the method of acknowledgment/deletion
  The method to acknowledge/delete diagnostic information messages can be specified.
- Font setting
  The font and font size used in the SCS Maintenance Support Tool window can be specified.
- Color selection
  The background color and text color can be specified.

Setup Tool consists of the following tabs:

- General
  Allows settings for the entire SCS Maintenance Support Tool
- Diagnostic Information
  Allows settings for the Diagnostic Information window

Displaying Setup Tool

Click the [Setup Tool] button on the toolbar of the SCS Status Overview window or the SCS State Management window. SCS Maintenance Setup dialog box appears.

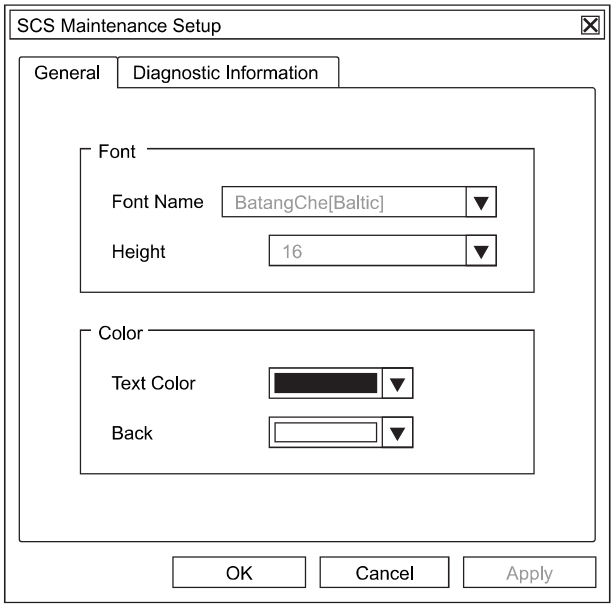

Figure A6.3-1 General Tab of SCS Maintenance Setup Dialog Box

General tab

Make settings related to the overall appearance of the window including font and text color in the "General" tab.

Font

The setting items related to font are as follows.

- Font name
  This item is used to select a font name. The font specified here is used in all windows related to SCS Maintenance Support Tool. The default font installed in SENG becomes the initial font.
- Height
  This item is used to select a font size. The font size specified here is used in all windows related to SCS Maintenance Support Tool.

Color

The setting items related to color are as follows.

- Text color
  This item is used to select a text color. The text color specified here is used in all windows related to SCS Maintenance Support Tool.
- Back
  This item is used to select a text background color. The background color specified here is used in all windows related to SCS Maintenance Support Tool.

Diagnostic Information tab

Make settings for operations specific to the Diagnostic Information window in the "Diagnostic Information" tab.

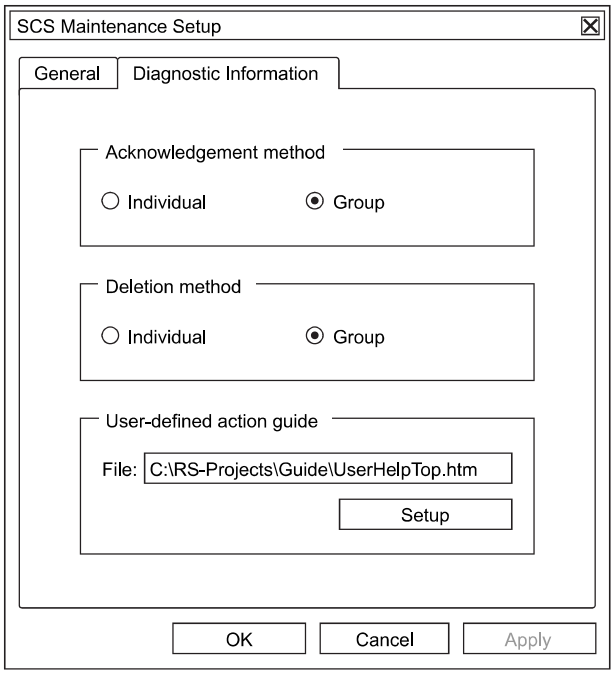

Figure A6.3-2 Diagnostic Information Tab of SCS Maintenance Setup Dialog Box

Method of acknowledgment

The setting items related to the method of acknowledgment are as follows.

- Individual
  Select this option to acknowledge the diagnostic information messages individually. It is recommended to use [Individual] during a normal operation.
- Group

Select this option to acknowledge all diagnostic information messages in a batch.

Method of deletion

The setting items related to the method of deletion are as follows.

- Individual
  Select this option to delete the diagnostic information messages individually. It is recommended to use [Individual] during a normal operation.
- Group
  Select this option to delete all diagnostic information messages in a batch.

IMPORTANT

If you select [Group] as the acknowledgement/deletion method, all diagnostic information messages displayed in the screen become the target of the acknowledging/deleting operation. So, you should not use this function during normal plant operation; use it only temporarily when testing, etc.

User-defined action guide

In the help dialog box for each diagnostic information message, a help text regarding the causes and resolution for the occurred message can be displayed as a guidance. Copying the default User Defined Action Guide and editing the contents can create a new user-defined action guide. The procedure is as follows:

1. Click the [Setup] button. The dialog box is displayed to specify the folder for copying the default action guide.
2. Click the [OK] button after specifying a folder. Then the file will be copied. The file name will be UserHelpTop.htm. The file name should not be changed.
   Edit the copied guide accordingly so as to create a new user-defined action guide.

SEE ALSO For more information about how to create a user-defined action guide, refer to:

"■ User-defined action guide" in H6.3, "Diagnostic information message help function" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

A7. Virtualization platform

ProSafe-RS runs not only on physical computers but also on virtual machines on the virtualization platform. This section describes an outline of the virtualization platform, the system configuration, the software environment, and precautions.

Terminology

This section describes virtualization and related terms.

Virtualization is a technology to make a single unit of physical hardware look like multiple logical units of hardware, or to make multiple units of physical hardware look like a single unit of logical hardware. In this document, we mainly deal with the technique that makes it look like there are multiple computers in the server.

- Virtualization software

  Refers to the software that realizes virtualization.

- Virtualization host computer

  Refers to a server on which virtualization software is installed and that is able to make it look like there are multiple computers in it.

- Virtual machine

  Virtualization can make it look like there are multiple computers on the virtualization host computer, and these pseudo computers are referred to as virtual machines.

- Host OS

  Refers to the OS operating as the foundation on the virtualization host computer.

- Guest OS

  Refers to the OS running the virtual machines.

- Thin client

  Refers to a client computer that contains minimum functions and performance and that is used for user interface.

A7.1 Outline of virtualization platform

In this document, the virtualization platform indicates the platform for integrating multiple computers with Yokogawa system products installed in the server. Hyper-V is used for the virtualization software.

In the virtualization platform, Vnet/IP functions on virtual machines are realized by using generic network card and Vnet/IP Interface Package instead of using Vnet/IP interface card. A virtual machine with this Vnet/IP communication function is referred to as a virtual Vnet/IP station.

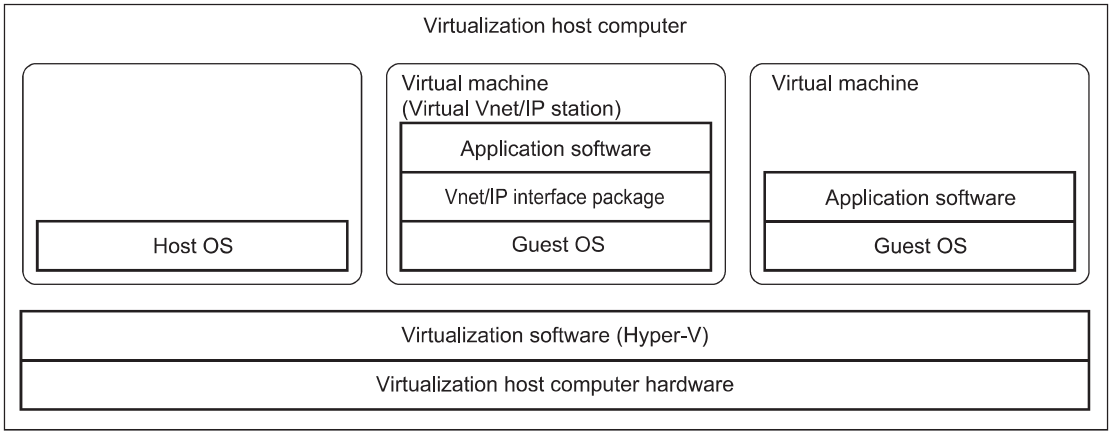

Figure A7.1-1 Hypervisor type virtualization host computer

Operation of the virtual machines on the virtualization host computer is performed on the thin client remotely connected via the network.

SEE ALSO

For more information about detailed functions of virtualization platform, refer to:

A., “Overview” in Virtualization Platform Setup (IM 30A05B20-01EN)

For more information about how to operate the virtualization host computer, refer to:

B., “Operating virtualization host computers” in Virtualization Platform Setup (IM 30A05B20-01EN)

For more information about how to set up a thin client, refer to:

C., “Setting up thin clients” in Virtualization Platform Setup (IM 30A05B20-01EN)

For more information about procedure to set up ProSafe-RS running on virtualization platform, refer to:

A2.2.2, “Setup Procedure for ProSafe-RS Running on a Virtual Machine on the Virtualization Platform” in Installation Guide (IM 32P01C50-01EN)

For more information about virtualization platform IT security setting, refer to:

1., “Overview” in Virtualization Platform Security Guide (IM 30A05B30-01EN)

For more information about IT security setting for ProSafe-RS running on virtualization platform, refer to:

1., “Overview” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

A7.2 System configuration of virtualization platform

The following figure shows an example of the system configuration of the virtualization platform.

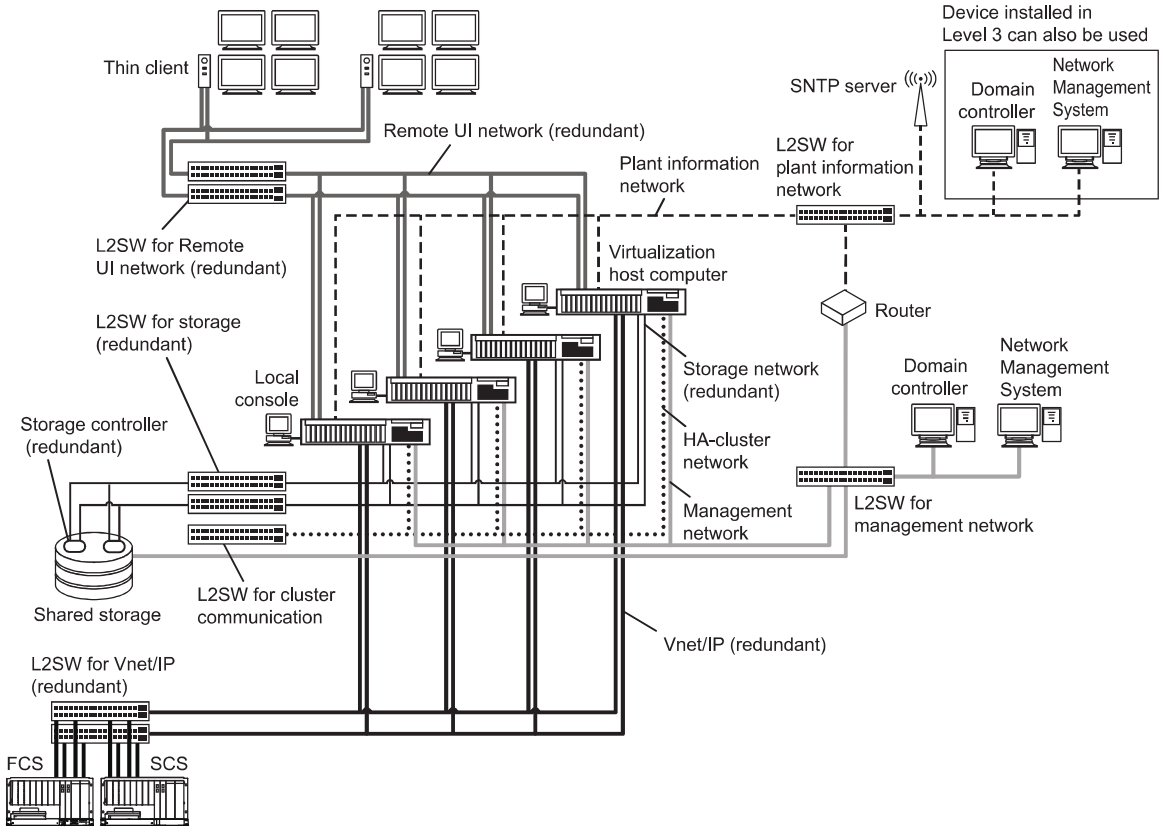

Figure A7.2-1 Example of system configuration of virtualization platform

ProSafe-RS R4.04.00 and later software can run on the virtual machines of the virtualization platform.

SEE ALSO

For more information about hardware on which the virtualization platform runs, and Yokogawa system products running on virtualization platform virtual machines, refer to:

IA system products virtualization platform (GS 30A05B10-01EN)

A7.2.1 Virtualization host computer

Virtualization host computers in the virtualization platform environment have the following structures:

- Single structure
- HA cluster structure (cluster structure with increased availability)

If HA cluster structure is used for increased virtualization server availability, live migration and failover functions can be used.

Live migration

Live migration is a feature that enables you to move active virtual machines to another virtualization host computer without stopping them. With this feature, you can apply security patches to the host OS or replace the hardware of the virtualization host computer without shutting down the virtual machines.

Disabling automatic live migration

In the virtualization platform environment, the default settings are changed to disable automatic live migration.

TIP

Automatic live migration is configured to be disabled in the following scenarios:

- When the resources of virtual machines are over committed in a virtualization host computer that constitute an HA cluster
- When the network that the virtual machines connect is specified in [Protected network] and its communication is interrupted.

However, automatic live migration may not be suppressed sometimes. For example, if you shutdown a host OS while a virtual machine is active in a virtualization host computer that forms a part of an HA cluster, live migration occurs automatically.

Failover

Failover is a function to restart the virtual machines of a virtualization host computer that stops due to an error, on another virtualization host computer in an HA cluster. This function is used to reduce the down time of a system when a virtualization host computer stops due to an error.

Restoration by restarting the virtual machine by using failover runs in the same way as [OS startup after unexpected shutdown].

Apart from the HA cluster failover that is explained in this section, there is another function called replication failover.

Failover conditions

Failover occurs in the following scenarios:

- When an active virtualization host computer stops due to an error.
- When communication is interrupted in both the management network and the HA-cluster network on an HA cluster that consists of three or more virtualization host computers.

Automatic restart of virtual machines

If the guest OS of a virtual machine with failover settings stops responding, the virtual machine restarts automatically. Unlike failover, the virtual machine restarts on the virtualization host computer that the virtual machine is originally allocated.

Restoration by restarting the virtual machine runs in the same way as [OS startup after unexpected shutdown].

Replication

Replication is prohibited for virtual machines where the Engineering Server Function, the Safety System Engineering and Maintenance Function, or iDefine is installed and virtual machines where SCS simulator runs. This is because the replica image created may have a missing or inconsistent database.

So, use the Version Control Tool to make appropriate backups during engineering, and if a storage failure occurs and the project database is corrupted, use the Version Control Tool to restore the projects.

The following table shows the applicability of replication and online backup and the enable/disable of Volume Shadow Copy Service (VSS) for packages other than the above.

Table A7.2.1-1 Applicability of replication for packages

Model	Name	Replication	Online backup	VSS	Remarks
RS4H2100	SOE Viewer Package	Applicable	Applicable	Enable: Applicable Disable: Applicable	
RS4H2200	SOE OPC Interface Package	Follow Exaopc specifications	Follow Exaopc specifications	Follow Exaopc specifications	Exaopc is internally used.
RS4H2300	Forced I/O Viewer Package	Applicable	Applicable	Enable: Applicable Disable: Applicable	

A7.2.2 Thin client

Thin client is a terminal that you use to operate the virtual machines on a virtualization host computer through remote connection. In the virtualization platform environment, Microsoft Remote Desktop Protocol is used as the connection protocol.

Number of virtual machines that you can connect simultaneously from a thin client

You can connect a thin client to multiple virtual machines simultaneously, but this consumes a lot of resources from the thin client. If too much resources are consumed, the remote connection may be disconnected. If that happens, verify the memory usage of the thin client and reduce the number of virtual machines that are simultaneously connected.

TIP

For information on how to check the thin client resource usage, contact YOKOGAWA.

Connecting a virtual machine and the USB devices of a thin client

This section describes whether you can use the USB devices that are connected to a thin client from a virtual machine.

You can use the following thin client USB devices from a virtual machine:

- Speaker
- USB storage devices

You can use these devices by configuring the corresponding settings in the virtual machine and the thin client.

A7.3 Software environment

This section describes the software environment of the components.

A7.3.1 Virtualization host computer

This section describes the software environment of the virtualization host computer.

Host OS

This section describes the software environment of the host OS.

OS

The following operating systems are supported as the host OS:

- Windows Server 2016 Datacenter Edition Desktop Experience
- Windows Server 2019 Datacenter Edition Desktop Experience
- Windows Server 2022 Datacenter Edition Desktop Experience

IT Security Tool

The IT Security Tool, which is used to configure IT security settings of the host OS, is provided in the software medium for the virtualization platform.

Virtual machine

This section describes the software environment of the virtual machine.

OS

The following operating systems are supported for virtual machines:

- Windows Server 2016 Standard Edition Desktop Experience
- Windows Server 2019 Standard Edition Desktop Experience
- Windows Server 2022 Standard Edition Desktop Experience

Available combinations of host OS and virtual machine OS

The following table shows the available host OS and virtual machine OS combinations.

Table A7.3.1-1 Available combinations of host OS and virtual machine OS

Host OS	Virtual machine OS		
	Windows Server 2016 Standard Edition	Windows Server 2019 Standard Edition	Windows Server 2022 Standard Edition
Windows Server 2016 Datacenter Edition	Yes	No	No
Windows Server 2019 Datacenter Edition	Yes	Yes	No
Windows Server 2022 Datacenter Edition	Yes	Yes	Yes

Vnet/IP interface package

In a physical environment, Vnet/IP stations use a dedicated card for Vnet/IP communication. In a virtualization platform environment, Vnet/IP stations use the Vnet/IP interface package and a general network adapter for Vnet/IP communication.

You must install the Vnet/IP interface package on a virtual machine before installing YOKOGAWA system products.

The following sections describe the important notes for Vnet/IP communication in the virtualization platform environment.

SEE ALSO For more information about notes of Vnet/IP communication in virtualization platform environment, refer to:

A7.4.1, “Precautions related to Vnet/IP communication on the virtualization platform” on page A7-13

A7.3.2 Thin client

This section describes the software environment of the thin client.

Operating system

The thin clients that are supported in the virtualization platform environment use the following operating systems:

- Windows 10 IoT Enterprise LTSC 2021
  (hereafter referred to as Windows 10 IoT)
- ThinOS 9.1

Yokogawa RDP Monitoring Software

If you use Windows 10 IoT, YOKOGAWA provides the Yokogawa RDP Monitoring Software in the software medium for virtualization platform. This software detects communication errors between virtualization host computers and thin clients.

The Yokogawa RDP Monitoring Software behaves as follows:

- It considers an interruption in communication for three seconds or more including signing out by user, as a communication error.
- It displays a user notification dialog box when an error is detected.
- It notifies users of errors in all communication channels when multiple virtual machines are connected.

IT Security Tool

The IT Security Tool, which is used to configure IT security settings in Windows 10 IoT, is provided in the software medium for the virtualization platform.

A7.3.3 License

You need a license to use the Vnet/IP interface package. After installing YOKOGAWA system products, assign the license to the virtual machine.

The virtual Vnet/IP stations without licenses are the same as the Vnet/IP stations that are not connected to the Vnet/IP network cable.

SEE ALSO For more information about required OS license for virtualization host computer and thin client, refer to:

IA system products virtualization platform (GS 30A05B10-01EN)

A7.4 Precautions on the virtualization platform

This section describes precautions on Vnet/IP communication on the virtualization platform, and precautions on setting up ProSafe-RS for virtual machines.

A7.4.1 Precautions related to Vnet/IP communication on the virtualization platform

This section describes precautions related to Vnet/IP communication on the virtualization platform

License

You need a license to use the Vnet/IP interface package. After installing YOKOGAWA system products, assign the license to the virtual machine.

The virtual Vnet/IP stations without licenses are the same as the Vnet/IP stations that are not connected to the Vnet/IP network cable.

Security

You must control the administrative privileges of the virtual Vnet/IP station to ensure the security of the Vnet/IP communication.

Functions not supported by the virtualization platform

The virtualization platform does not support the following functions:

Vnet/IP open communication

The virtualization platform uses the plant information network for open communication, and does not use Vnet/IP open communication. Attempting to install the Vnet/IP open communication driver will result in an error and installation will fail.

CI Server integration

The virtualization platform does not support CI Server integration. Also, wide area communication and narrow band communication supported by CI Server integration cannot be used.

Precision of time synchronization

The relative time synchronization precision between virtual Vnet/IP station and other stations are as follows:

- ±50 ms within the domain
- ±75 ms among domains

This precision does not apply to the relative time synchronization between stations other than virtual Vnet/IP stations, and remains the same as earlier.

Limitations related to IP address and network connectivity

The following limitations related to IP address and network connection applies to virtual Vnet/IP stations:

- Do not configure IP addresses 192.168.0.0 to 192.168.255.255 for virtual network adapters that are not used for Vnet/IP communication on the virtual machines.
- The virtual network adapters other than the Vnet/IP virtual network adapter cannot connect to the network in the range from 192.168.0.0 to 192.168.255.255 either directly or through network switches and routers.

L2SW segments within the Vnet/IP domain

The range that is connected to only an L2SW without devices such as layer 3 switches (hereinafter, referred to as L3SW) or V net routers is called the Vnet/IP domain. In the virtualization platform environment, the range connected by including this virtual L2SW is called the Vnet/IP domain.

In a virtualization platform environment, you can install up to seven L2SW segments within the Vnet/IP domain. This does not include virtual L2SW.

Notes when connecting SNTP server to the Vnet/IP network

When you connect the SNTP server to a Vnet/IP network on which virtual Vnet/IP stations are connected, and try to synchronize the network time with the absolute time, adopt any of the following network configurations:

- If a domain with one or more virtual Vnet/IP stations that are installed with Vnet/IP firmware is available, you must connect the SNTP server to that domain.
- If you cannot connect the SNTP server to a domain that satisfies the conditions mentioned earlier, or if the domain to which the Vnet/IP station belongs does not have stations installed with Vnet/IP firmware, configure the network by satisfying all the following conditions:
  - Install the SNTP server in a place where all the Vnet/IP stations that belong to a time group can communicate.
  - In this time group, include a minimum of one station that is installed with Vnet/IP firmware.
  - Specify the IP address of the SNTP server in the time group settings in the properties of the domain that has stations installed with Vnet/IP firmware.

TIP

The following stations are installed with Vnet/IP firmware:

- Stations installed with Vnet/IP interface card
- FCS that can connect to Vnet/IP
- SCS
- Vnet router
- Wide area communication router

A7.4.2 Precautions on using ProSafe-RS on a virtual machine

This section describes precautions on using ProSafe-RS on a virtual machine.

Resources required for a virtual machine

The following table shows an estimation of resources that are required for ProSafe-RS system to run in a virtual machine.

If you install multiple functions on a virtual machine, you must compare resources required for respective functions and assign the maximum value of them to the virtual machine. Ensure to total the required available space for the hard disk space.

If CENTUM VP software is also installed on the same virtual machine, the virtual machine must also meet the requirements for CENTUM VP software.

Table A7.4.2-1 Estimation of resources required for a virtual machine

Function and package	Type of setup	Number of CPU cores	Memory size (GB)	Hard disk space (GB) (*1)	Disk access speed (MB/s)
Engineering Server Function (*2)	Recommended setting	4	8	80	48
Safety System Engineering and Maintenance Function (iDefine not installed in the same virtual machine)	Recommended setting	4	8	80	48
Safety System Engineering and Maintenance Function (iDefine installed in the same virtual machine)	Recommended setting	4	12	80	48
SOE Viewer Package / SOE OPC Interface Package / Forced I/O Viewer Package (*3) (*4)	Recommended setting	2	4	80	16
SCS Simulator	Recommended setting (8 simulators)	3	5	-	16
	Small-scale setting (4 simulators)	2	5	-	16
License Management	Recommended setting	2	4	80	32
	Small-scale setting	1	2	40	8
File Server	Recommended setting	2	4	80	48
iDefine for ProSafe-RS (*5)	Recommended setting	4	8	80	32

*1: If the operation history database of Access Control and Operation History Management Package is placed on the virtual machine, at least 60 GB of additional disk space is required.
*2: Only the license of this package can be distributed alone to a virtual machine and run it as an AD Server.
*3: When installing these packages on the same virtual machine where the Engineering Server Function or the Safety System Engineering and Maintenance Function is installed, observe their operating environment requirements.
*4: The time taken for distribution performed with the Forced I/O Viewer Setup Tool of the Forcing I/O Viewer Package can be improved by increasing the disk access to 32MB/sec.
*5: When installing iDefine for ProSafe-RS in the same virtual machine as the Safety System Engineering and Maintenance Function, refer to the estimation for “Safety System Engineering and Maintenance Function (iDefine installed in the same virtual machine).”

TIP

For resources required when using Standard Whitelisting Software for Endpoint Security on virtual machines, contact YOKOGAWA.

Precautions for running live migration

You must stop SENG programs before you run live migration. If you run live migration while SENG programs are running, problems may occur for example creation of master database fails after online maintenance. To avoid such problems, you must handle a live migration as a maintenance task and prepare a plan to execute it.

Precautions after execution of failover

The virtual machine startup due to failover runs as “OS startup after unexpected shutdown”. After failover runs, perform the following tasks.

Use Project Comparing Tool or Database Validity Check Tool to check the status of database after failover runs. If necessary, roll back SCS project by using the database repair function of Database Validity Check Tool or Version Control Tool and reflect the changes that are made before failover runs to restore the project or the database.

Precautions when connecting remote desktop

Remote desktop connection is required between the virtual machines and the thin clients when using ProSafe-RS on the virtualization platform.

Precautions when connecting the remote desktop on the virtualization platform are as follows:

- Install the remote desktop session host role service on the virtual machines.
- Set the number of remote desktop connection sessions that can be connected to one virtual machine at the same time to 1.
- Disable the limit on the number of connected sessions for each user.
- It is recommended to limit the number of thin clients and users who can remotely connect to virtual machines to the minimum necessary.
- The ProSafe-RS and CENTUM VP remote operation monitoring servers cannot both be installed on the same virtual machine.

IMPORTANT

After setting up the remote desktop connection, follow these steps to apply the registry file:

1. Sign in to the virtual machine as an administrative user.
2. Mount the ProSafe-RS software medium.
3. In Explorer, navigate to the following folder in the ProSafe-RS software medium.
   `<Drive of ProSafe-RS medium>:\ProSafe-RS\RemoteDesktopService`
4. Double-click `Reg_FS_OFF.reg` in the folder.
5. Restart the virtual machine.

SEE ALSO For more information about how to set the number of sessions that can be connected simultaneously on remote desktop, refer to:

B1.6, “Changing session settings in remote connection” in Virtualization Platform Setup (IM 30A05B20-01EN)

For more information about how to grant permission for remote connection with thin clients and how to register users, refer to:

B1.4, “Configuring system products after installing” in Virtualization Platform Setup (IM 30A05B20-01EN)

For more information about setting to limit the number of thin clients and users that can be remotely connected to the minimum, refer to:

B2.5.6, “Limiting connections to virtual machines” in Virtualization Platform Setup (IM 30A05B20-01EN)

Precautions when using shared storage

If the path for shared storage is switched while SCS Test Function Window is being started, the start of SCS Test Function Window may fail.

If the start of SCS Test Function Window failed, restart it.

Precautions when using iDefine in the virtualization platform environment

Dongle Gateway, which is a Windows service, is required to use iDefine in the virtualization platform environment. The license for iDefine is authenticated via Dongle Gateway.

SEE ALSO For more information about Dongle Gateway specifications, refer to:

Dongle Gateway Installation and User Guide (PR03076-MAN-983_01)

Installing Dongle Gateway and inserting a USB dongle

Install Dongle Gateway on thin clients where IT security settings are applied, physical SENGs, or virtual machines with SENG software installed.

Insert a USB dongle into computers where Dongle Gateway is installed. If you install Dongle Gateway on a virtualized SENG, insert a USB dongle in the USB device server and have it recognized via the network.

With one USB dongle, you can use iDefine for the number of licenses granted to the dongle.

The following table shows the combinations of computers that can install Dongle Gateway and where to insert the USB dongle.

Table A7.4.2-2 Computers on which Dongle Gateway can be installed and where to insert the USB dongle

Computers on which Dongle Gateway can be installed	Where to insert the USB dongle	Remarks
Thin client	Thin client	Windows version
Physical SENG	Physical SENG	-
Virtualized SENG	USB Device Server (*1)	-

*1: Please contact YOKOGAWA for recommended products for USB Device Server.

SEE ALSO For more information about Dongle Gateway IT security setting, refer to:

"■ The users for using iDefine in a virtualization environment" in 2.2.3, "User/Group Management" in ProSafe-RS Security Guide (IM 32P01C70-01EN)

For more information about how to install Dongle Gateway, refer to:

Dongle Gateway Installation and User Guide (PR03076-MAN-983_01)

License authentication

To use iDefine in a virtualization platform environment, authenticate the license via Dongle Gateway.

IMPORTANT

- If the iDefine for the number of Dongle Gateway licenses granted to the USB dongle is already connected to the Dongle Gateway at the same time, trying to connect another iDefine will cause license authentication to fail.
- If communications between iDefine and Dongle Gateway are disconnected, such as if there is a communication error or if the USB dongle is pulled out, update of the license information will fail and the iDefine license will be invalidated. If communication between iDefine and Dongle Gateway is restored within 5 minutes and license information can be acquired, the iDefine license is re-activated and iDefine can be used. If the license information cannot be acquired, Dongle Gateway releases the license and becomes available from other iDefine.

SEE ALSO For more information about how to authenticate iDefine license via Dongle Gateway, refer to:

Dongle Gateway Installation and User Guide (PR03076-MAN-983_01)

Transfer of data files

The method to transfer files, such as the safety I/O list and data files to be exchanged with iDefine, to and from the guest OS of virtual machines differs from the method used for physical computers.

SEE ALSO For more information about how to extract and capture data files, refer to:

B2.8, "Copying files" in Virtualization Platform Setup (IM 30A05B20-01EN)

B. ProSafe-RS security

ProSafe-RS has the following security functions to prevent access to the system by unauthorized users and devices, and unintended changes caused by operation mistakes made by users.

- Security for the project database
  You can configure the SENG function so that the user is required to enter a password when changing the project data with SCS Manager. (Recommended)
- Security for access to SCS
  You can limit access to SCS from the outside based on the SCS security level. The user is required to enter a password when changing the SCS security level. (Mandatory)
- Security for the SCS Maintenance Support Tool
  On SENG, you can limit writing to SCS with the SCS Maintenance Support Tool by setting a password. (Recommended)
- Access control and operation history management
  Access control and operation history management can be performed on projects that are saved in the AD Server. You can also use the Access control and operation history management package.
- Countermeasures against threats to IT security
  ProSafe-RS security threats include attacks via the network, direct attacks by executing actions on an SENG, and analysis of important data carried out by stealing an SENG. The security features are designed to take measures against these types of security breaches.

This section provides an overview of the ProSafe-RS security function, and the main procedures for setting passwords and implementing security relating to unauthorized access and protection against unintended operations.

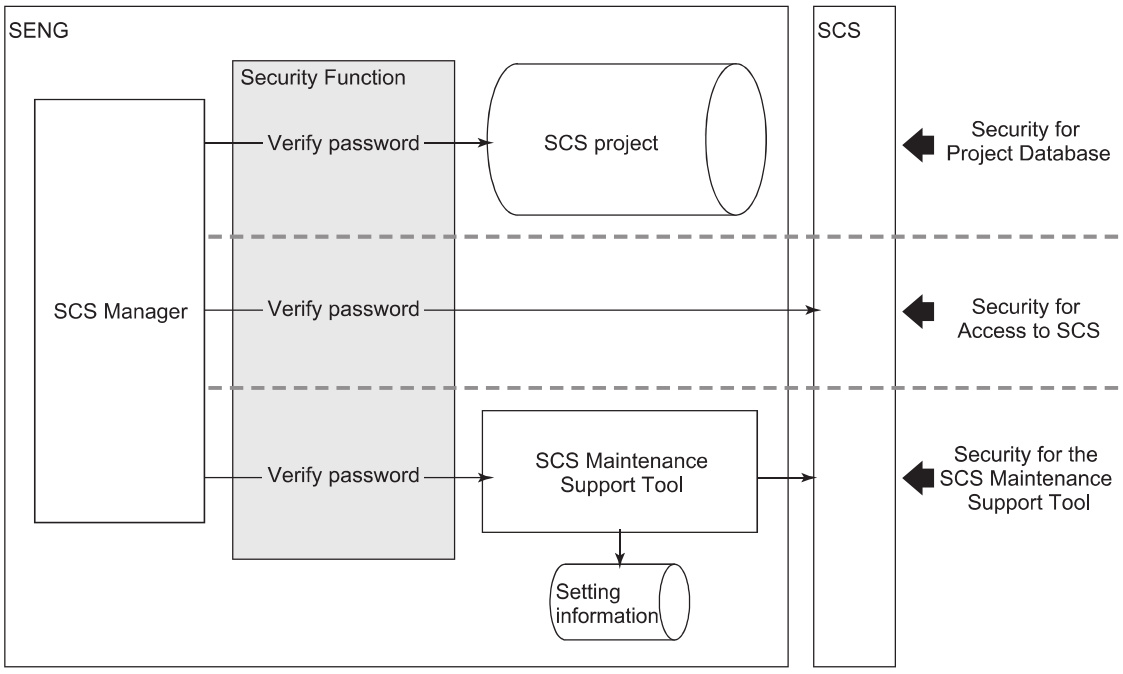

Figure B-1 Password-based security functions

B1. Overview of ProSafe-RS security

The figure below illustrates the security management of SCS and SENG in ProSafe-RS.

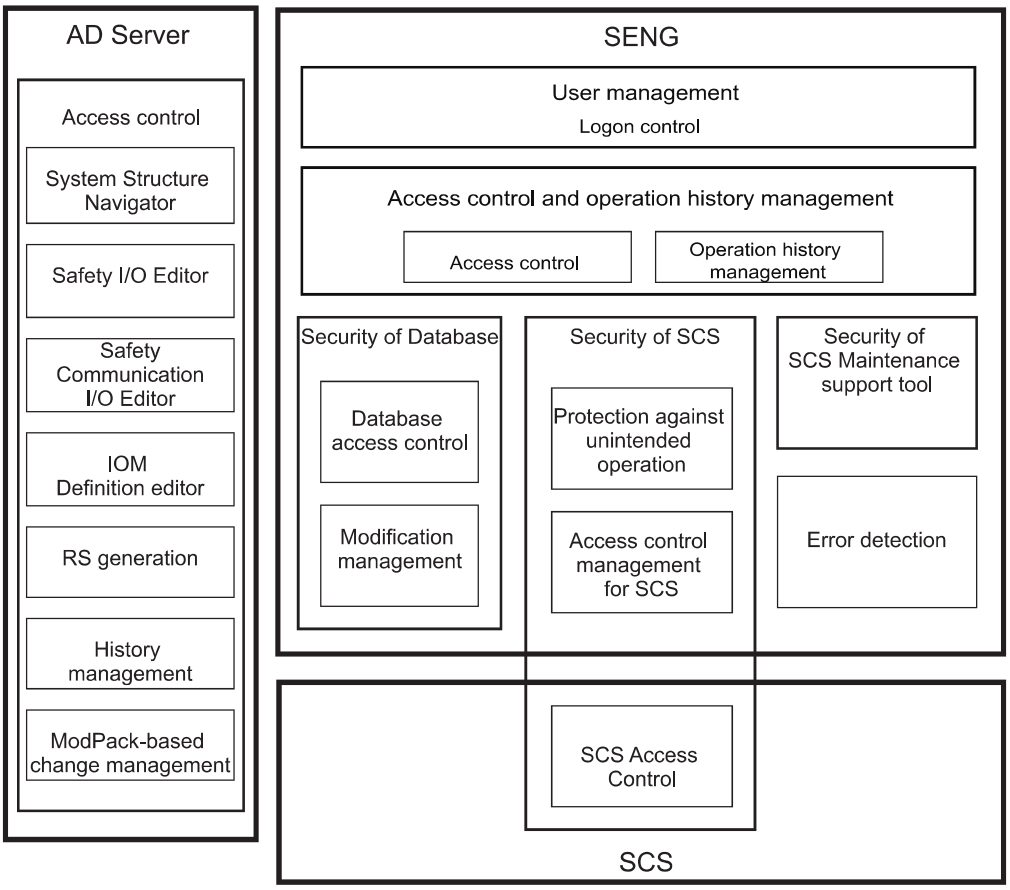

Figure B1-1 Overview of security management

IT security

This section describes the requirements for IT security.

For SENG, Windows OS is used as a platform. Therefore, it is necessary to prevent, detect, and recover from computer viruses and attacks from the external through the network. For example, there are countermeasure such as network access control using firewall and system backup.

In the CENTUM Integration Structure, it is necessary to consider comprehensive IT security including ProSafe-RS system and CENTUM system.

You can harden the security of the PC designated as a SENG terminal to enhance the ProSafe-RS IT security (PC hardening). This section describes the details regarding PC hardening and the setting guidelines.

TIP

When integrating ProSafe-RS with CENTUM VP, configure the security settings during installation of ProSafe-RS and installation of CENTUM VP, respectively.

When integrating ProSafe-RS with CS 3000, select Legacy model in IT security tool.

Configure the IT security of the computer that has iDefine installed by referring to iDefine Security Manual (PR03076-MAN-981_01).

If your security model is a legacy model, anyone will be able to start iDefine Test Manager.

If your security model is a standard or strengthened model, any user that belongs to the PSF_ENGINEER or PSF_ENGINEER_LCL group will be able to start iDefine Test Manager.

An example of registering a user to the user account

IT security enhancement for a PC can protect the ProSafe-RS system from the illegal access by any user other than the user of ProSafe-RS user groups. For protecting the ProSafe-RS system from the accidental mistaken accesses by the users of ProSafe-RS groups, the ProSafe-RS Security features should be used. By combining IT security enhancement for a PC and ProSafe-RS Security, you can fortify security of ProSafe-RS.

The typical examples of registering a ProSafe-RS user to the user groups are shown as follows:

(A) ProSafe-RS Engineer (Integrated with CENTUM VP)

ProSafe-RS Engineer user should be assigned to both PSF_ENGINEER group of ProSafe-RS and CTM_ENGINEER group of CENTUM VP.

(B) ProSafe-RS Engineer (Not Integrated with CENTUM VP)

ProSafe-RS Engineer user should be assigned only to the PSF_ENGINEER group.

(C) Maintenance and service persons

The user who requires the role for upgrading SENG software to newer versions, maintaining or changing the hardware components such as I/O modules should be assigned only to the PSF_MAINTENANCE group.

(D) Network and System Administrator (User who is responsible for network maintenance)

This user is considered as the administrative user of Windows environment in SENG. This user needs to be assigned only to the PSF_MAINTENANCE group.

(E) User account for emergency attention (For domain or parallel management in standard model)

When ProSafe-RS system is running in an Windows domain environment, if the domain controller encounters an abnormality, no one can logon to the SENG with the domain account. You need to prepare the user accounts who are assigned to the PSF_MAINTENANCE_LCL group for an emergency attention. If the domain controller encounters an abnormality, user can logon to the SENG with this user account, then maintain and operate ProSafe-RS.

Though the users in the above groups are all granted with the Write permission to all the Project folders, in the cases of (C) and (D), the Write permission is not required. An engineer should define a password by using the security feature of the project database and keep the password as secret to the users whom you do not grant the Write permission so as to protect the project database. Moreover, ProSafe-RS provides security features for accessing the SCS and for Maintenance Support Tool. These security features can be utilized in accordance with the role of the users so as to protect the database and SCS from the accidental operation mistakes.

SEE ALSO For more information about user groups of ProSafe-RS, refer to:

2.2, “User/Group Management” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

For more information about user groups of CENTUM VP, refer to:

CENTUM VP Installation (IM 33J01C10-01EN)

Database security management

The database has the following security functions.

Access control of the SCS project database

It is possible to set a password for the database used in an SCS project; so that only users who know the password are allowed to make changes to the database. It is also possible to set whether or not to allow users who do not know the password to refer to the database.

Security for AD projects

The following security functions are available for AD projects:

- Management of users who are permitted to access AD projects
- Access control of AD project data

Modification management

This function manages the changes made to SCS projects. It has the following functions:

- Backup
  SCS projects are registered and managed in AD Server.
- Version management
  This function manages the history of changes made to SCS projects.
- Master database management
  SENG always maintains the backup SCS project that keeps the same SCS database with the one running on the SCS.
- Saving modification files
  When you use the Access Control and Operation History Management Package, the changes made to the project database downloaded to the SCS are saved.

Security management of SCS

The SCS has the following security functions.

SEE ALSO For more information about details on the security of SCS, refer to:

B3., “Security of SCS” on page B3-1

Prevention of SCS operation mistakes made by users

When a user attempts to perform the following operations on the SCS, the user is prompted to confirm the execution of the operation in order to prevent operational mistakes.

- Offline download
- Online change download
- Master database offline download
- IOM download

- I/O lock
- SCS security level change

Access control to SCS

- Access control based on the security level
  Access from outside to SCS is controlled by SCS security levels. Password must be set for changing the SCS security levels (to Level 1 or Level 0). The SCS security level can only be operated using the SCS security level operation function, by users who know the password.
- Access control for each user
  When the Access Control and Operation History Management Package is applied, you can control operations on SCS for each user.

Security management of SCS Maintenance Support Tool

In SCS Maintenance Support Tool, write access to SCS is controlled by setting a password. If the Access Control and Operation History Management Package is used, operations of the SCS Maintenance Support Tool can be controlled for each user.

SCS Status Overview window, Diagnostic Information window, Setup Tool

The SCS Status Overview window, Diagnostic Information window and Setup Tool are protected by passwords. Each of these functions is launched as read-only unless the correct password is specified.

In the case of the SCS Status Overview window, the password is checked when calling this window from SCS Manager. The Diagnostic Information window and Setup Tool inherit the password of the SCS Status Overview window when they are launched.

When the Access Control and Operation History Management Package is applied, enter the name and password of the engineer.

Message Cache Tool

Message Cache Tool is protected by a password. It is launched as read-only unless the correct password is specified.

SOE Viewer

No password is set up for SOE Viewer because no writing operations to an SCS are performed on SOE Viewer.

Forced I/O Viewer and Forced I/O Viewer Setup Tool

Forced I/O Viewer and Forced I/O Viewer Setup Tool do not perform password authentication at startup.

Access control of AD server

You can control access to individual files and functions of an AD project for each user. You can also set access rights to the files and folders in AD Server according to the role of the user.

System Structure Navigator

You can set the rights to register, unregister, back up, and restore RS projects, edit RS project comments, and delete SCS.

- **Safety I/O Editor**

  You can set the rights to create and delete safety I/O lists and assign safety I/O.

- **Safety Communication I/O Editor**

  You can set the rights to create and delete safety communication I/O lists and assign safety communication I/O.

- **IOM Definition Editor**

  You can set the rights to create and delete nodes and I/O modules.

- **RS generation**

  You can set the rights to run RS generation.

- **History management**

  You can set the rights to set and delete labels.

- **ModPack change management**

  You can set the rights to perform operations for each ModPack operation category.

B2. Security for project database

This section describes security for project databases.

Setting a password for project databases

You can assign a password to a database to prevent unauthorized users from making changes to the database in SCS projects. Users without entering the password can be given permission for read only operation.

Passwords can be specified for the following.

- For each SCS Project
- For each POU

The reading and writing right for the whole project and the access right for each POU can be controlled using the security function of the SCS project and the security function of each POU.

Set a different password for each SCS Project.

If higher level of security is required, set a password for each important POUs.

You need to set different passwords for each SCS project. These passwords should be different from the one for the SCS security level.

Database files in RS projects should not be changed from tools other than the ProSafe-RS software.

Setting a password for the SCS project

It is possible to set a password for the SCS project so that only authorized users can make changes to the SCS project.

The following settings can be made.

- Password for the SCS Project
  If you set a password for the SCS project, users are asked to enter the password when they open the SCS project.
- Accessing without a password
  If you do not know the password, the SCS project can be opened in read-only mode without entering the password after checking [Read Only].

  In this status, the users are not allowed to edit the application logic or generate databases.

  Operations on the SCS, such as using the forcing function and downloading data, are possible in the read-only status.

TIP

Security for operations on SCSs and security for SCS project databases are not related.

The security against operations on SCSs is changed using the SCS security level operation function. By changing the SCS security level, using the forcing function and downloading data can be allowed.

How to set passwords

1. Select [Project Properties] from the [File] menu of SCS Manager;
   The following dialog box appears.

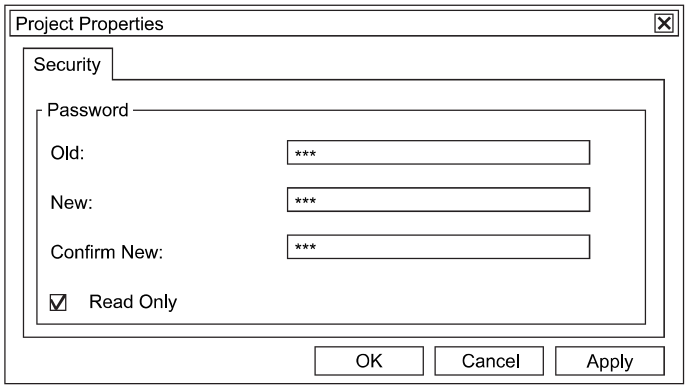

Figure B2-1 Project Properties dialog box

2. Enter the current password in the [Old:] field.
3. Enter a new password in the [New:] field, and once again in the [Confirm New:] field. The password consists of up to eight case-sensitive, alphanumeric characters.
4. If you want to access the project but do not know the password, check [Read Only] option.
5. Click the [OK] button.

Setting password for each POU

It is possible to set a password for each POU so that only the authorized users can reference and change important POUs.

When users attempt to edit a POU for which a password is set, they are required to enter the password. If you do not know the password, you are not allowed to reference or print the POU.

Even when a project is opened in read-only mode, the POU is readable after entering the password of the POU.

How to set passwords

1. Select a POU for which you want to set a password.
2. Select [Properties] from the menu displayed by clicking the right mouse button. The following dialog box appears.

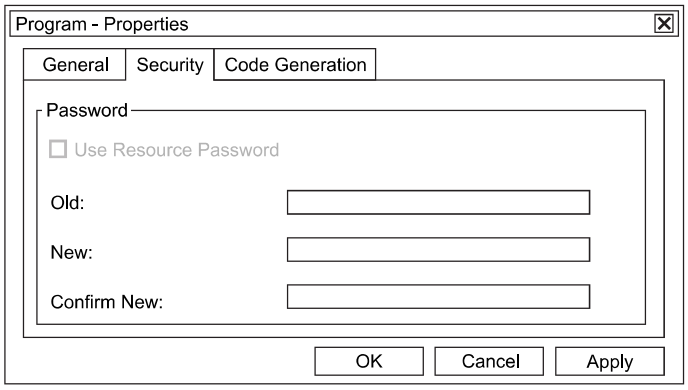

Figure B2-2 Dialog box for setting a password for a POU

3. Enter the current password in the [Old:] field.
4. Enter a new password in the [New:] field, and once again in the [Confirm New:] field. The password consists of up to eight case-sensitive, alphanumeric characters.

5. Click the [OK] button.

B3. Security of SCS

SCS security levels provide adequate security through specifying the passwords. Passwords for different security levels can be set for each SCS.

- Setting and changing passwords
- Changing SCS security levels

Note that it is necessary to return the SCS security level to Level 2 before closing an SCS project.

This section describes how to set passwords for changing SCS security levels and how to change the levels.

IMPORTANT

No password has been set after executing offline download and master database offline download. Make sure to set passwords again.

TIP

The access to SCS is controlled by SCS itself according to its security level. Operations on the SENG is not be prohibited according to the SCS security level, however.

SEE ALSO

For more information about security level of SCS, refer to:

A3.2.2, “Security level of SCS” on page A3-15

How to set and change passwords

The password that is used to change the SCS security level is stored within the SCS. This password can be set or changed from the Set SCS Security Level dialog box.

IMPORTANT

No password has been set after executing offline download and master database offline download. Make sure to set a password at this stage.

1. Select [Maintenance] from the [Tools] menu of SCS Manager.
   The Maintenance Launcher menu appears.
2. Select [Set SCS Security Level] from the Maintenance Launcher menu.
   The Set SCS Security Level dialog box appears.

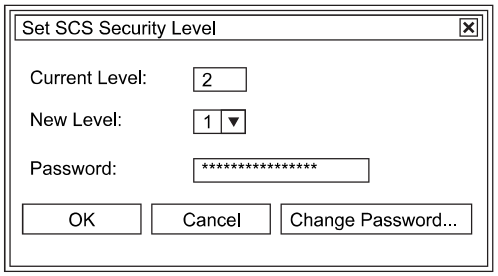

Figure B3-1 Set SCS Security Level dialog box

3. Click the [Change Password] button.

The Change SCS Security Level Password dialog box appears.

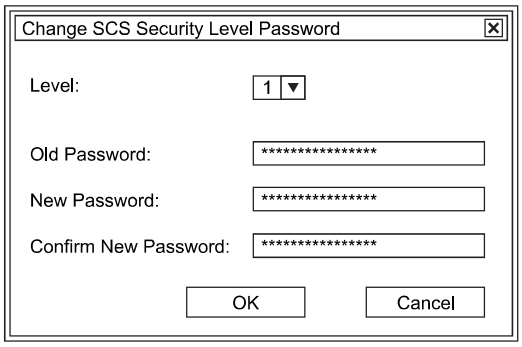

Figure B3-2 Change SCS Security Level Password dialog box

4. Select the security level for which you set a password in [Level:].
   It is necessary to set one password for changing to Level 1 and one for Level 0, respectively.
5. Enter the current password in the [Old Password:] field.
6. Enter a new password in the [New Password:] field, and once again in the [Confirm New Password:] field.
   The passwords you have entered appear as a series of asterisks (*).

   A password is a maximum 16 of single-byte alphanumeric characters and following symbols including a space character. The password is case-sensitive.

   ! " # $ % & ' ( ) * + , - . / : ; < = > ? @ [¥] ^ _ ` { | } ~

   You do not need to enter [Old Password:] if you have not set any password before, or if you have just executed an offline download or a master database offline download.
7. Click the [OK] button.
   The confirmation dialog box appears.

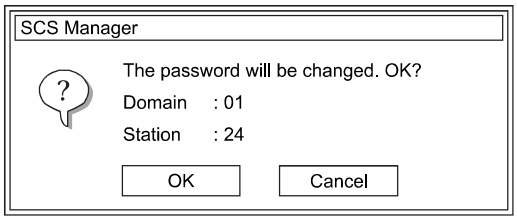

Figure B3-3 Confirmation dialog box

8. Click the [OK] button.
   Both new and old passwords will be sent to SCS. If the password is successfully changed, the dialog box notifying the success appears. The new password becomes valid. If the password change fails, a dialog box will be displayed to notify the failure.

How to change SCS security levels

The SCS security level can be changed in the Set SCS Security Level dialog box of SCS Manager.
The table below shows the combinations of levels for which security level changes are allowed via operations on the Set SCS Security Level dialog box.

Table B3-1 Security levels that can be changed through operations in the Set SCS Security Level dialog box

Current SCS security level	New SCS security level (*1)		
	Level 2	Level 1	Level 0
Level 2	-	Yes (*2)	Yes (*2)
Level 1	Yes (*2)	-	Yes (*2)
Level 0	Yes(*3)	No	-

*1: Yes: The security level can be changed.
No: The security level cannot be changed.
*2: The security level can be changed to the target SCS security level.
*3: Security level changes can be made only in SCS simulator.

To change the security level, you need to enter the password. However, you don't need to enter a password when changing the security level from Level 1 to Level 2.

You cannot raise the security level from Level 0 to Level 2 from the Set SCS Security Level dialog box. In SCS Simulator of SCS Test Functions, however, you can raise from Level 0 to Level 2 on the Set SCS Security Level dialog box. This operation does not require a password.

CAUTION

To set the SCS security level back to Level 2 after changing to Level 0, you must restart the SCS, execute offline download, or execute master database offline download. In particular, be sure to execute offline download if you used break points in debugging of the application logic.

These operations require stopping of the system. When you change the security level to Level 0, do so very carefully considering the consequences of the system stop.

The SCS security level can be changed in the following procedure.

1. In SCS Manager, open an SCS project whose security level you want to change.
2. Select [Maintenance] from the [Tools] menu of SCS Manager.
   The Maintenance Launcher menu appears.
3. Select [Set SCS Security Level] from the Maintenance Launcher menu.
   The Set SCS Security Level dialog box appears. The current security level is displayed in [Current Level:]; this item is display only and cannot be changed.

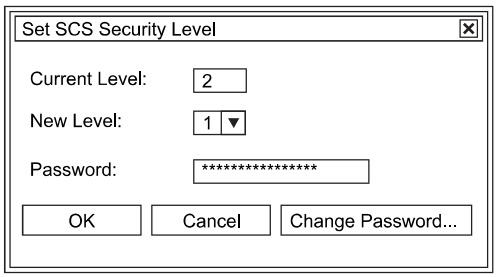

Figure B3-4 Set SCS Security Level dialog box

4. Select the security level you want in [New Level:] and enter the password for the level you want in [Password:] text box.
   All characters you enter are displayed as asterisks (*).
5. Click the [OK] button.
   The confirmation dialog box appears.

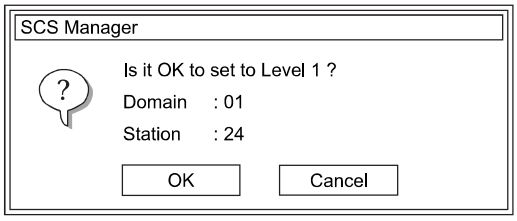

Figure B3-5 Confirmation dialog box (when changing to Level 1 or Level 2)

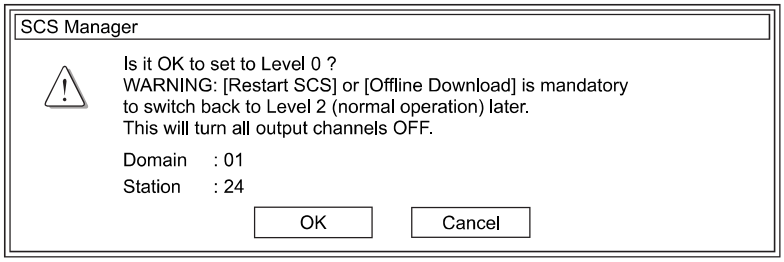

Figure B3-6 Confirmation dialog box (when changing to Level 0)

6. Click the [OK] button.
   When changing the security level to Level 0, the following dialog box appears to confirm the change again. When you set the level back to Level 2 from Level 0, the system stops. Confirm that this does not cause any problems. To proceed with the change, click [OK].

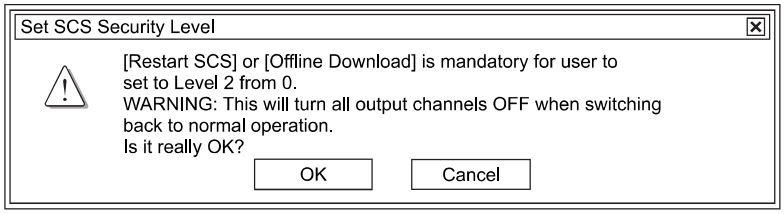

Figure B3-7 Dialog box confirming change to Level 0

If the security level of SCS is changed, the message showing the result of change is displayed.

The error message is displayed if the security level could not be changed.

Confirming the SCS security level reset by SCS Manager

If the security level of SCS project currently opened in SCS Manager is not Level 2, the confirmation dialog box prompting to reset the security level to Level 2 appears when closing it.

IMPORTANT

This dialog box is for confirmation only. Open the corresponding SCS project again and change the security level using the Set SCS Security Level dialog box.

The confirmation dialog box appears in the following timings.

- When closing an SCS project by exiting SCS Manager

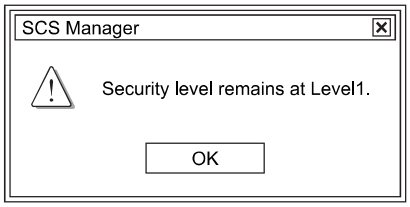

Figure B3-8 Example of Confirmation dialog box (when closing by exiting SCS Manager)

Clicking the [OK] button to exit SCS Manager leaves the security level unchanged.

- When closing an SCS project by opening another SCS project

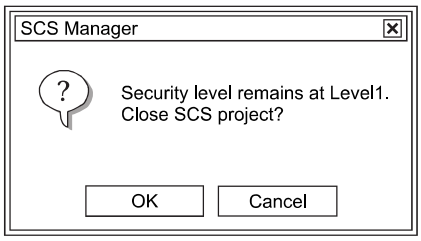

Figure B3-9 Example of Confirmation dialog box (when closing by opening another SCS project)

Click the [OK] button to close the currently opened SCS project without changing its security level, and then open another SCS project.

Click the [Cancel] button to keep the currently opened SCS project opened, and another SCS project will not open.

B4. NIU status and security

The N-ESB bus module (S2EN501) that is installed in the node interface unit (NIU) is equipped with a maintenance port.

For the security reason, you should disable the maintenance port when operating the system.

The status of the NIU is determined by the status of the NIU maintenance port and operating mode of the NIU. This section describes the status of the NIU maintenance port, NIU operating mode, and shifting of the NIU status.

Overview of the NIU status and tools

The status of the NIU is determined by the status of the NIU maintenance port and operating mode.

- Status of the NIU Maintenance Port
  The status of the NIU maintenance port can be either enabled or disabled. The status of the maintenance port can be switched between enabled and disabled by using the NIU maintenance port settings tool that is called from the SCS State Management window in the SCS Maintenance Support Tool.
- Operation mode of the NIU
  The NIU operation mode can be either online mode or maintenance mode. The operation mode can be switched between online mode and maintenance mode by using the N-IO maintenance tool in the computer that is connected to the maintenance port.

  The N-IO maintenance tool can be used if the NIU maintenance port is enabled.

IMPORTANT

The Node number setting tool and FieldMate Validator are included in the N-IO maintenance tool.

B4.1 Status of the NIU maintenance port

You can run the NIU maintenance port settings tool and enable or disable access from an external device such as a computer connected to the maintenance port of the N-ESB bus module.

Disabled status

The disabled status of the maintenance port prohibits access from the maintenance port.

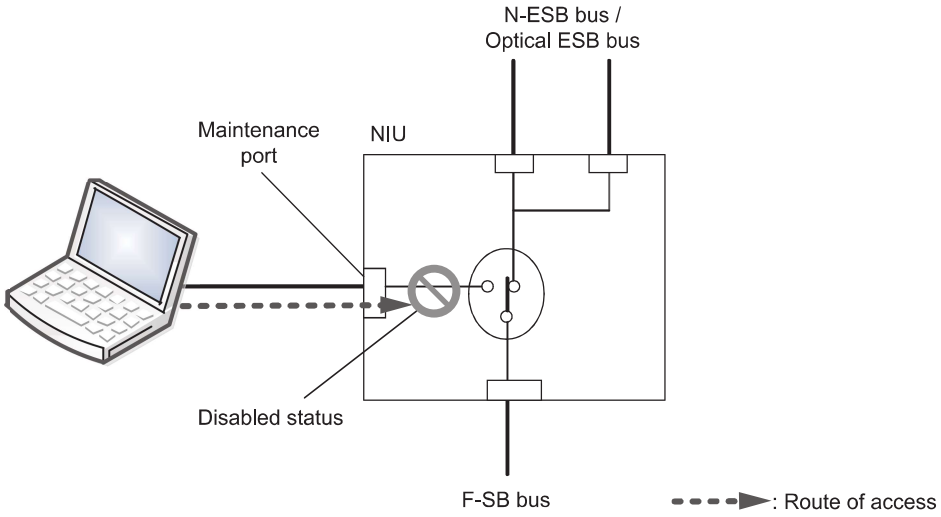

Figure B4.1-1 Disabled status of the maintenance port

Enabled status

The enabled status of the maintenance port allows access from the maintenance port.

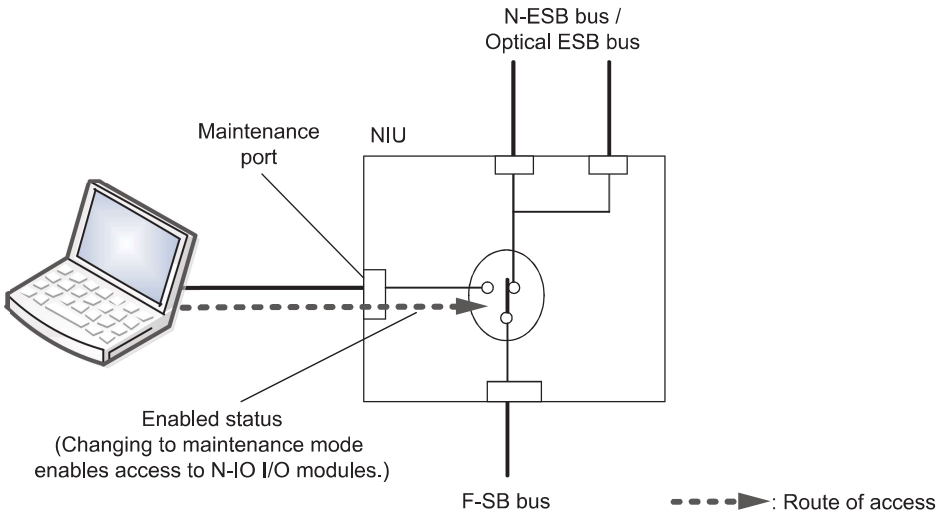

Figure B4.1-2 Enabled status of the maintenance port

SEE ALSO For more information about how to enable/disable the maintenance port, refer to:

I4.5, “NIU maintenance port setting tool” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

B4.2 Operation mode of the NIU

The NIU operation mode can be either online mode or maintenance mode.

Online mode

In online mode, you can access the N-IO I/O modules from the N-ESB bus or the optical ESB bus.

You cannot access the N-IO I/O modules from the maintenance port.

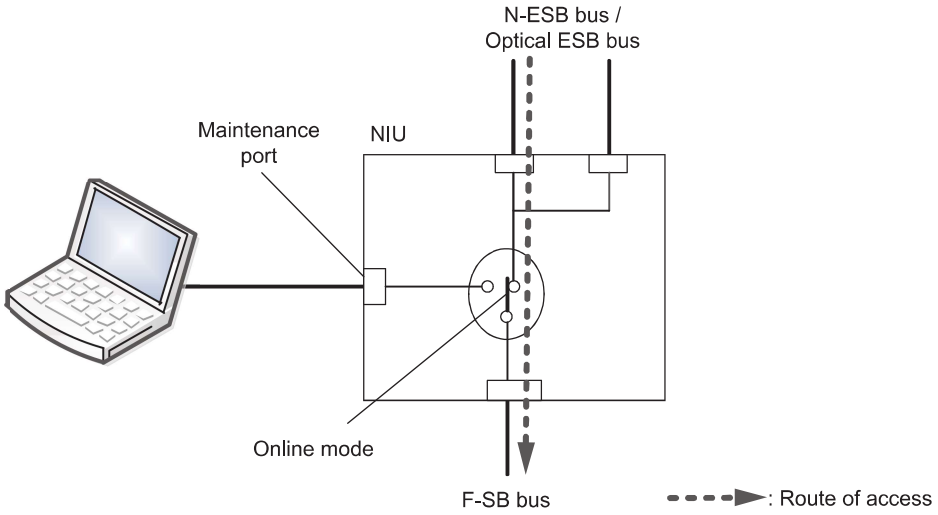

Figure B4.2-1 Online mode

Maintenance mode

In maintenance mode, you can access the N-IO I/O modules from the maintenance port.

You cannot access the N-IO I/O modules from the N-ESB bus or the optical ESB bus.

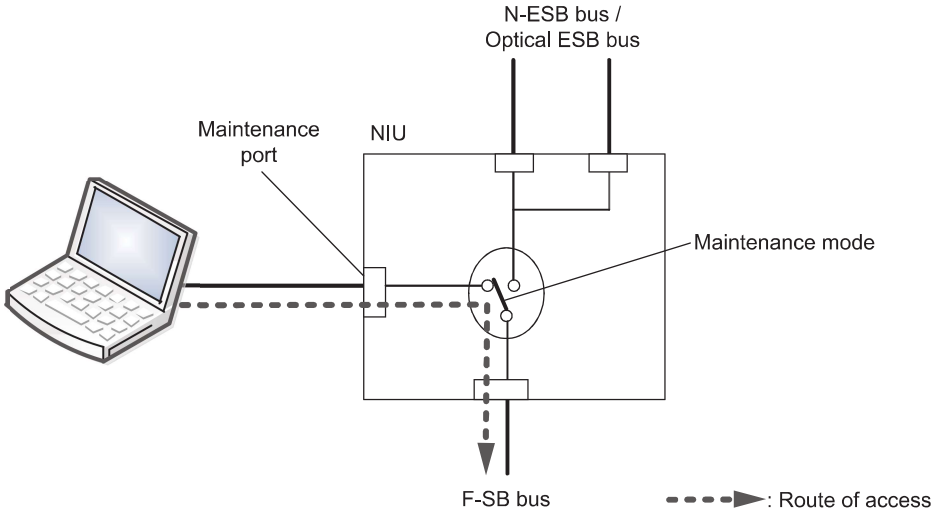

Figure B4.2-2 Maintenance mode

Switching between operation modes

This section describes how to switch between the NIU operation modes.

- Switching from the online mode to the maintenance mode

When the maintenance port is enabled, perform the "maintenance instructions" operation from the N-IO maintenance tool connected to the maintenance port to switch from the online mode to the maintenance mode.

- Switching from the maintenance mode to the online mode.
  Perform on of the following to switching from the maintenance mode to the online mode.
  - Perform the "release maintenance instructions" operation from the N-IO maintenance tool connected to the maintenance port.
  - Disconnect the USB cable that is connected to the maintenance port
  - Turn off the power of the NIU, then turn it on

IMPORTANT

When the node number setting tool is used as a N-IO maintenance tool, the unit will switch to the maintenance mode when a node address is configured. After the node address is configured, the unit will switch to the online mode.

TIP

- Switching the maintenance mode of the dual-redundant N-ESB bus modules
  Because the N-ESB bus modules are dual-redundant, when you change the operation mode on one side, the operation mode of the other side will switch accordingly.

SEE ALSO

For more information about Node number Setting tool, refer to:

F2.1.1, “Using the Node Number Setting Tool” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about FieldMate Validator, refer to:

manual of FieldMate Validator

B4.3 Shifting the Status of the NIU

The following figure shows the status and the operation mode of the NIU maintenance port, and the status shift with regards to external access.

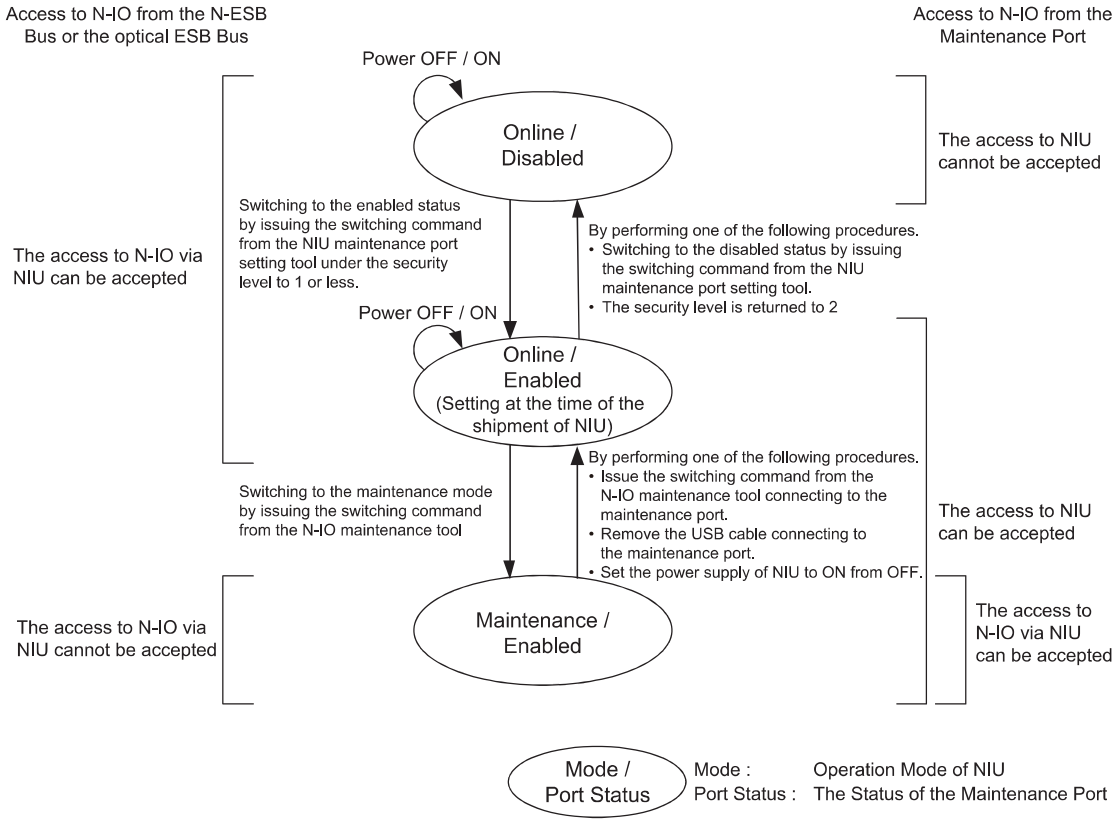

Figure B4.3-1 NIU status shift

The following table shows the factory settings of the N-ESB bus modules (S2EN501) that are installed in the NIU.

Table B4.3-1 NIU factory settings

Target	Setting	Status
Operation mode	Online mode	The CPU module accesses the N-IO modules from the N-ESB bus and optical ESB bus through the NIU.
Status of the maintenance port	Enable	You can access the NIU from the N-IO maintenance tool.
Node number	Not set	The NIU is not operating correctly. You need to set the node number before connecting to the SCU.

B4.4 Checking the status of the maintenance port of the NIU

The status of the NIU maintenance port can be checked through the following tools and functions.

Status display

The status of the NIU maintenance ports can be checked by using the following tools:

- SCS Status Overview window of SENG
- SCS Status Display view of HIS
- SCS Node Status Display dialog box of HIS

Message

The SCS generates the following messages for the status and status change of the NIU maintenance port, and the status change of the NIU operation mode:

- A diagnostic information message that notices the status of the NIU maintenance port
- A safety control station status change message that notices the status change of the NIU maintenance port
- A safety control station status change message that notices the status change of the NIU operation mode

IOM report

The status of the NIU and NIU maintenance port is displayed in the IOM report.

B5. Security of SCS Maintenance Support tool

SCS Maintenance Support Tool has a security by setting a password to be entered when starting related windows. A password is set for each SENG.

This section describes how to set passwords for the SCS Maintenance Support Tool.

The password described in this section is not applicable if the Access Control and Operation History Management Package is used. Instead, the user enters the password that is set for each user in the Access Control and Operation History Management Package when starting the SCS Maintenance Support Tool.

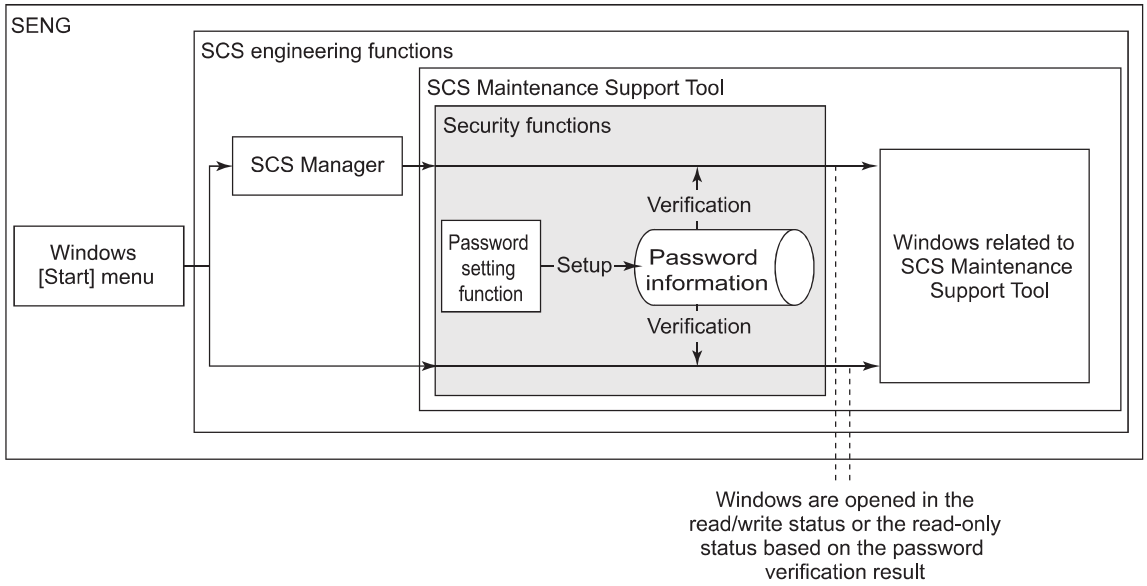

Figure B5-1 Security functions of Maintenance Support tool

TIP

No security is set in order to use SOE Viewer as it only displays information.

Setting a password for the SCS Maintenance Support Tool

The SCS Maintenance Support Tool requires a password entry every time you start a window to ensure the security of the SCS access. Password needs to be set for each SENG.

Each tool in the SCS Maintenance Support Tool can be operated for security by entering a password at the start of each tool. When the password entry is cancelled, the tools' operations are disabled for security and the window is in the read-only mode.

The following table shows whether tools can be operated or not when the password is entered and when password entry is cancelled.

Table B5-1 Operation of SCS Maintenance Support tool

Tool	Operations provided security	Inputting a password	Without inputting a password
SCS State Management Window	IOM Download	Enabling operation	Read Only
	Output Enable Operation	Enabling operation	Read Only
	Output Module Start Operation	Enabling operation	Read Only
	Setting Time	Enabling operation	Read Only
Diagnostic Information Window	Confirmation and Deletion of Diagnostic information	Enabling operation	Read Only
Setup Tool	Setting and change of display font, color and operating methods for confirming or deleting messages	Enabling operation	Read Only
SOE Viewer	Display of events of SCS and generation of report	Enabling operation	Enabling operation
Message Cache Tool	Setting of message collection, initialization of TRIP information in SCS and storage and deletion of cache data.	Enabling operation	Read Only

How to set and change a password for SCS Maintenance Support tool

The Change Maintenance Support Password dialog box is used to specify or change the password that the user must enter when starting the SCS Maintenance Support Tool.
To use SCS Maintenance Support Tool, make sure to set the password first.

TIP

No password is set automatically after installing SENG. Make sure to set a password at this stage.

1. Open the window related to SCS Maintenance Support Tool from SCS Manager or [Start] menu of Windows.
   When the window requiring a password is opened, the Input Maintenance Support Password dialog box appears.

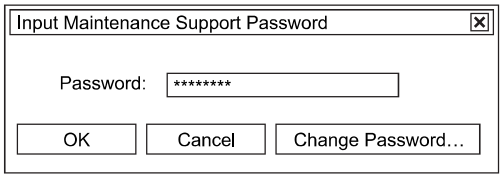

Figure B5-2 Input Maintenance Support Password dialog box

2. Click the [Change Password] button.
   The Change Maintenance Support Password dialog box appears.

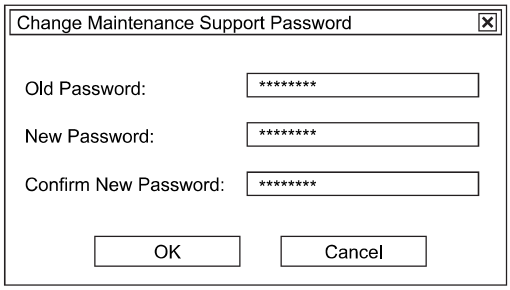

Figure B5-3 Change Maintenance Support Password dialog box

3. Enter the current password in the [Old Password:] field. Enter a new password in the [New Password:] field, and once again in the [Confirm New Password:] field.
   The passwords you have entered appear as a series of asterisks (*).
4. Click [OK].
   The password is set.

Specification for passwords

- A password is a maximum 16 of single-byte alphanumeric characters and following symbols including a space character. The password is case-sensitive.
  ! " # $ % & ' ( ) * + , - . / : ; < = > ? @ [¥] ^ _ ` { | } ~
- Set a password for each SENG-installed PC.
- There is no password when SENG is installed for the first time.
- Set a password when starting the SCS Maintenance Support Tool for the first time.

How to enter SCS Maintenance Support tool password

To start SCS Maintenance Support Tool, the correct password must be entered.
Once you enter the correct password, you are allowed to perform writing and customization operations using SCS Maintenance Support Tool.

IMPORTANT

If you fail to enter the correct password, SCS Maintenance Support Tool is started in the read-only status.

1. Open the window related to SCS Maintenance Support Tool from SCS Manager or [Start] menu of Windows.
   When the window requiring a password is opened, the Input Maintenance Support Password dialog box appears.

   If the current window is called from another window of SCS Maintenance Support Tool, the Input Maintenance Support Password dialog box does not appear, because the security is inherited.

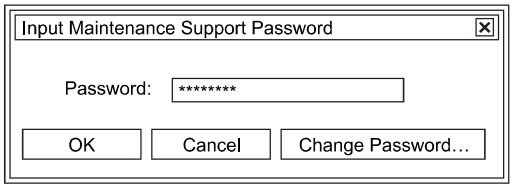

Figure B5-4 Input Maintenance Support Password dialog box

2. Enter a password in [Password:] text box.

All characters you enter are displayed as asterisks (*).

3. Click the [OK] button.
   If you enter the correct password, the window is opened in the read/write status.

   Click the [Cancel] button to start the window related to SCS Maintenance Support Tool in the read-only status.

   Click the [Change Password] button to display the Change Maintenance Support Password dialog box.

B6. Access control and history management

When using the Access Control and Operation History Management Package, the functions that can be used by a user are restricted based on the access rights for that user.

SEE ALSO For more information about Access control and operation history management package, refer to:

E., “Access Control/Operation History Management functions” in Engineer's Reference Manual (IM 32P04B10-01EN)

User management

The package has a function that enables management of the users who work with SCS Manager and the SCS Maintenance Support Tool. In AD Suite, you can set access rights to the targets of operation for each user role. The user management function is used to register and delete engineers and manage the passwords of engineers. It also keeps records of the operations that were performed by each user.

Access control

The access control function enables you to check engineers who operate the SENG, restrict login or operations on the SENG, and control authorization of engineering operations.

In AD Suite, you can define access rights to files and folders on the AD Server and various functions for all users who perform engineering and maintenance of ProSafe-RS.

Operation history management

This function enables to keep a log of the operations performed by an engineer on the SENG and save the changed project information when a download to an SCS is performed.

In AD Suite, operation history management is available for the following editors and features:

- Safety I/O Editor, Safety Communication I/O Editor, and IOM Definition Editor of AD Organizer
- SCS Manager, builders, and tools including the SCS Maintenance Support Tool
- RS Generation Manager

The change history on all builders and editors is saved on the AD Server and can be viewed in the history window of AD Organizer.

Appendix 1. Glossary

The following terminologies are used in the User's Manual of this product.

Table Appendix 1-1 Terminologies used in User's Manual

Terminology	Meaning
Access control	A functionality to restrict user operations in each SENG. A SENG terminal where access control is applied requires an engineer name and password entry to perform particular operations. When an engineer tries to make an engineering operation, the engineer can not execute the desired action unless the engineer has the permission to perform the operation. Access Control and Operation History Management Package is required.
ADL	Inter-station data link block of CENTUM FCS
AIO module	Generic term for analog input/output modules. Universal type I/O modules with defined AI and AO are included.
AIO/DIO module	Generic term for analog input/output modules and discrete input/output modules. Universal type I/O modules with defined AI, AO, DI, and DO are included. Communication modules are not included.
Alarm class	Alarm information added to diagnostic information messages. On SENG, diagnostic information messages are displayed in different colors with different alarm marks according to the alarm class. • Class 1 (serious alarm) • Class 2 (moderate alarm) • Class 3 (minor alarm) • Class 4 (notification alarm)
Alarm priority	Process alarm information that is needed when ProSafe-RS is integrated with CENTUM. Alarm priorities are in five levels: high-priority alarm, medium-priority alarm, low-priority alarm, logging alarm, and reference alarm.
Alarm Priority Builder	The builder used to define process alarm priority levels when ProSafe-RS is integrated with CENTUM. For each alarm priority level, you can define the output style and alarm action on occurrence/recovery of process alarms generated in SCS.
Alarm processing table	The table that defines the process alarms' display color and alarm priority corresponding to the alarm status on CENTUM HIS. On ProSafe-RS, you can import the alarm processing table defined on CENTUM to use it for reference.
Alarm Processing Table Builder	The builder used to import the Alarm Processing Table defined on CENTUM into SCS project.
All output shutdown	To shut down all the output modules when the CPU stops due to a fatal error. During all output shutdown, the fail-safe values are output.
All Program Copy (APC)	In dual-redundant CPU modules, to copy the memory contents of the control-side module to the stand-by-side module.
Analog Input/Output modules with HART function	An analog input/output module that supports HART communication

Continues on the next page

Table Appendix 1-1 Terminologies used in User's Manual (Table continued)

Terminology	Meaning
Application logic execution function	The function that monitors the safety condition of the plant and performs pre-determined safety operations on detecting any hazards. Specifically, it denotes the following features and is used as the generic term for these features: • Input processing of the process data from the field • Execution of user-defined application logic • Outputting process data to the field • Communication data I/O (Subsystem communication, Safety Subsytem communication) • Inter-SCS safety Communication • SCS Link Transmission • Self-diagnosis
Application run time	The proportion of the time in a scan period of the SCS during which the CPU is working for the application execution functions. (Represented in percentage.)
Automatic IOM download	For dual-redundant AIO/DIO modules of a running SCS, if only the standby-side AIO/DIO module is replaced for maintenance, the configuration information is automatically downloaded from the control-side module to the standby-side module after replacement. This function is called automatic IOM download.
Behavior at abnormal calculation	The setting item of an SCS that specifies whether the SCS is stopped when an abnormal calculation, such as an overflow in floating-point data calculation, has occurred due to a defect in the application logic. It also refers to the behavior of the SCS specified with this setting.
Binding List View	The view on SCS Manager that is used to associate the variables for inter-SCS safety communication between producer SCS and consumer SCS. See Workbench User's Guide for more information.
Binding variable	Variables that link variables of producer SCS and variables of consumer SCS performing inter-SCS safety communication. The producer variables of a producer SCS need to be grouped for each consumer SCS that receives them. The consumer variables of a consumer SCS also need to be grouped for each producer SCS that sends them. These groups are called "binding groups."
Build	The operation that is run on SCS Manager to generate the database to be downloaded to a target SCS.
Burnout	One of input module action specifications when Thermocouple or Resistance Temperature Detector input has an open circuit. Selectable options at open circuit are to clamp the input to an upper or a lower limit or to disable burnout actions. Clamping to an upper limit is called burnout upscale and clamping to a lower limit is called burnout downscale.
CENTUM	In the user's manuals of ProSafe-RS, the generic term that refers to CENTUM VP and CENTUM CS 3000.
CENTUM project folder	The folder storing the data of the CENTUM project to be connected to SCS projects. When the system is integrated with CENTUM, you need to specify this folder in the SCS Project Properties dialog box.

Continues on the next page

Table Appendix 1-1 Terminologies used in User's Manual (Table continued)

Terminology	Meaning
CI Server	Integrated operation and monitoring system developed by YOKOGAWA
Clean Project	The command on SCS Manager that deletes the files created in the previous run of the build command. After Clean Project is run, only offline downloading is possible.
Communication I/O Lock Window	This SENG window is used to lock/unlock I/O data for subsystem communication and safety subsystem communication. You can set values to the I/O data locked through this window. This window is used on SENG for maintenance and testing purposes.
Communication module	A module used to implement communications with systems (such as PLCs) from other companies. It is treated as one of the input/output modules.
Consumer SCS	SCS which receives data in inter-SCS safety communication.
Control bus driver	A driver software on a PC necessary to perform control bus communications via V net or Vnet/IP network.
Control bus interface card	An interface card installed to a PC to allow it connecting to V net.
CPU module	The main module that works to implement the control performed by SCS.
Cross Reference Analyzer	One of the Safety Analyzers. A Safety Analyzer which shows the following information in the screen or in an analysis report. • Differences between the previously downloaded application (which is currently running on the SCS) and the application that is to be downloaded • The scope that will be affected by downloading the new application This tool enables you to narrow the scope of re-testing when the application logic has been modified.
Cycle Time	Another name for the scan period of application logic execution functions. It is defined by setting the [Cycle Timing] in the Resource Properties dialog box of SCS Manager.
Database Validity Check Tool	The tool that checks the mutual validity of the work database, the master database and the SCS database within an SCS. In addition, database can be repaired.
Debug mode	A mode of SCS Manager that is used in target tests. See Workbench User's Guide for more information.
Defined word	Definition of a constant expression, TRUE/FALSE Boolean expression, or keyword. Defined words are replaced by their corresponding expressions during compiling.
Diagnostic information message	SCS sends diagnostic information messages for detected faults and for the operation on the safety functions to notify user of events. In a system integrated with CENTUM, diagnostic information messages of ProSafe-RS are sent to HIS and treated as system alarms.
Dictionary View	The view on SCS Manager used to set parameters and define variables of POUs. See Workbench User's Guide for more information.

Continues on the next page

Table Appendix 1-1 Terminologies used in User's Manual (Table continued)

Terminology	Meaning
Digital input/output module	The name of the modules that handle discrete inputs/outputs.
DIO module	General term for discrete input/output (digital input/output) modules. Universal type I/O modules with defined DI and DO are included.
Discrete input	Input of a discrete (ON/OFF) signal
Discrete output	Output of a discrete (ON/OFF) signal
DO shutoff switch	A switch that shuts off the output of all DO channels when a critical failure that can prevent normal output with the DO channel of the universal type I/O module has occurred. This switch can be activated automatically by setting the parameter for the DO channel.
ENG	A computer installed with engineering function packages for system generation and maintenance of CENTUM.
Engineers' account builder	The builder used to register engineers that are managed by the access control/operation history management function. It is also used to define access rights of engineers. All the settings made on this builder are saved in the Engineers' account file.
Error level	The level of errors occurred in SCS. Errors are classified in three levels: fatal error, major error, and minor error. With a fatal error, the SCS cannot continue operation. With a major error, the SCS can continue operation but some of the safety functions are disabled. Minor errors do not affect safety functions of the SCS. The users are notified of the error level by diagnostic information message.
ESB bus (Extended serial backboard bus)	The bus for connecting the CPU node and I/O nodes of SCS. ESB bus coupler modules are installed in the CPU node while ESB bus interface modules are installed in I/O nodes. These modules are connected using ESB bus cables.
Ethernet communication module	The name of a module that supports Modbus TCP communication protocol. SCS uses this module to perform Modbus slave communication.
Event log file	The file containing SOE (Sequence Of Event) events which is stored in SCS. You can save this file to SENG.
Expanded test function	The function to perform SCS simulation tests using SCS simulators on multiple computers and running them in coordination. This function is available with the use of the Expanded Test package of CENTUM.
Extend scan period automatically	The function that automatically extends the scan period of application logic execution functions when the load of SCS becomes heavy.
External communication function	The function of SCS for exchanging data with external systems. It is designed so as not to affect the application logic execution functions and comprises the following features: • CENTUM Integration Function • SOER Function • Modbus Slave Communication Function • Diagnostic information collection • PRM-supported HART on-demand communication

Continues on the next page

Table Appendix 1-1 Terminologies used in User's Manual (Table continued)

Terminology	Meaning
External communication function block	Function blocks used as the interface for data setting to SCS from Modbus master in Modbus slave connection or data setting to SCS from a CENTUM station when ProSafe-RS is integrated with CENTUM. External communication function blocks are interference-free.
FAST/TOOLS:	SCADA system developed by Yokogawa
FCS simulator	A simulator program offered for CENTUM systems. It simulates the behavior of FCS on a computer.
Field Control Station (FCS)	A component of CENTUM system which performs process control in plants.
Field network	It denotes the network between ProSafe-RS and YFGW410.
Field wireless backbone network	A backbone network stipulated in ISA100.11a. It denotes the network between YFGW410 and YFGW510.
Field wireless network	A field wireless network for industries based on ISA100.11a. It denotes the network between YFGW510 and GS01.
Field wireless system	It denotes the wireless system consisting of YFGW410, YFGW510, GS01, field network, field wireless backbone network and field wireless network.
Fire and gas communication	This function is used for safe communication with GS01 wireless gas detector through management stations for YFGW410 field wireless network and access points for YFGW510 field wireless network, after implementing S2LP131 fire and gas communication module in SCS.
Forcing	The function to lock and change the values of inputs/outputs or variables of SCS. It is used on SENG for maintenance of SCS or debugging of application logic. This function is available while the security level of the target SCS is set to 1 or 0.
Forced I/O Viewer function	The function that displays a list of information such as variables locked in the SENG lock window.
Function Block Diagram (FBD)	A language defined in IEC 61131-3.
Function Block (FB)	POU defined in IEC 61131-3. Constituents incorporated in FBD/LD/ST.
Function (FU)	POU defined in IEC 61131-3. Constituents incorporated in FBD/LD/ST.
Generation time	The time at which build was run for an SCS project to generate SCS database. In the SCS State Management window or a system report, a generation date is shown for each type of database: POU DB, Variable DB, System DB, and Integration DB.
Global switch	An element of CENTUM FCS which can be set to the same logical value in all the FCSs within a domain. By using the SCS global switch communication feature of SCS link transmission, values of some global switches can be sent or received between CENTUM stations (FCS, APCS, or GSGW) and SCS.
Global variable	A variable which can be accessed by any POU.

Continues on the next page

Table Appendix 1-1 Terminologies used in User's Manual (Table continued)

Terminology	Meaning
Grouping override function block	A special type of override function block. Grouping override function blocks belonging to the same group can be controlled so that no more than one function block within the group is overriding at the same time.
Hardware Architecture View	A view on SCS Manager that graphically displays the SCS and the network. See Workbench User's Guide for more information.
High current output function	A functionality that can use several DO channels together to put high current in analog digital I/O module
Human Interface Station (HIS)	A component of CENTUM system. It is a computer installed with a set of operator interface package software that enable operation and monitoring. Monitoring of SCS is also possible from HIS.
iDefine-config file	An XML format file that is created by exporting the ProSafe-RS engineering data edited with iDefine. It contains information on POUs, internal variables, FB instances, parameters, and tag names. The information in this file can be reflected in the SCS project after imported to AD Organizer.
iDefine for ProSafe-RS	A functional safety lifecycle management tool for ProSafe-RS developed by Trinity It has functions such as Cause & Effect and State Analysis. In the ProSafe-RS User's Manual, iDefine for ProSafe-RS is described as iDefine.
iDefine Test Manager	A feature for using the test functions of ProSafe-RS from iDefine. By running iDefine Test Manager, you can test the application logic created with iDefine using the test functions of ProSafe-RS from iDefine. You can perform the logic simulation test, SCS simulation test, and target test of ProSafe-RS.
I/O Lock Window	The window used to lock/unlock the input/output channels of the AIO/DIO modules in SCS. You can set values to the input/output variables connected to the channels that have been locked through this window. This window is used on SENG for maintenance and testing purposes.
I/O Parameter Builder	The builder used to make settings of the parameters (I/O parameters) for nodes, input/output modules, and channels of SCS that specify the behavior of them.
I/O shutoff switch	A switch that shuts off the I/O of AI (2-wire), AO, and DI when a critical failure that can prevent normal output with the AO channel of the universal type I/O module has occurred. When the I/O shutoff switch is activated, the DO shutoff switch is activated at the same time. This switch can be activated automatically by setting the parameter for the AO channel.
I/O Wiring View	The view on SCS Manager used to create or delete input/output modules in SCS, set node addresses, define wiring between channels and variables. See Workbench User's Guide for more information.
Input module	General term for the analog input module, the digital input module, and the universal type I/O module to which input channels are defined.
Input valuable	Variables connected to the channels of an input module, which are used in POUs.

Continues on the next page

Table Appendix 1-1 Terminologies used in User's Manual (Table continued)

Terminology	Meaning
Input value at error occurrence	A predefined value that is output when a value from an input module becomes abnormal.
Input/Output module	Generic term for AIO/DIO modules and communication modules.
Integration with CENTUM	ProSafe-RS can be used by integrating with CENTUM VP or CENTUM CS 3000. In the User's Manuals of ProSafe-RS, the integration with CENTUM VP or CENTUM CS 3000 is referred to as "Integration with CENTUM."
Integrity Analyzer	One of the Safety Analyzers. The tool used to analyze the safety of the created application logic. The users are required to use this tool to detect the use of FB/FU that are unacceptable as safety functions. The results of analysis can be shown on the screen or output in the analysis report.
Interference-free	Does not interfere safety application.
Internal variable	Variables not connected to an input/output module, which are available for use in POUs.
Inter-SCS Communication Lock Window	The window used to lock/unlock the input/output data for inter-SCS safety communication on an SCS by SCS basis. You can set values in the inter-SCS safety communication FB of the SCS locked through this window. This window is used on SENG for maintenance and testing purposes.
Inter-SCS safety communication	Safety communication used to implement safety loops among multiple SCS. Safety communication by SCS link transmission is not included in this communication. Safety loops are implemented by defining the function blocks dedicated for inter-SCS safety communication (producer FB and consumer FB) and binding variables.
IOM Control Right Switching Tool	The tool used for switching the control right of AIO/DIO modules placed in redundant configuration. Redundantly configured communication modules cannot be switched with this tool.
IOM download	Processing which downloads the input/output configuration information such as I/O parameters to input/output modules. This processing may occur during online change download after changing I/O parameters of input/output modules using I/O Parameter Builder.
IOM download tool	A tool that is needed when input/output modules have been replaced due to a malfunction, etc. It is run from the SCS State Management window and downloads the input/output configuration information stored in the master database of the SCS project to the input/output modules.
IOM Report	A dialog box which shows the status and error-related diagnostic information about an individual input/output module. IOM Report is called up from the SCS Maintenance Support Tool.
IOM Reset Function	A function that allows you to restore an I/O module from SENG. Only in the cases when an I/O module stops because of failures on the field side, you can restore the module by manually executing IOM download from SENG.
Ladder Diagram (LD)	A language defined in IEC 61131-3.

Continues on the next page

Table Appendix 1-1 Terminologies used in User's Manual (Table continued)

Terminology	Meaning
Legacy model	A model of information security settings set on SENG. This model should be used when the standard model of security settings is too tight or when compatibility with other system is required.
Library project	A project database that can be used as a library independent of specific SCS. The functions and function blocks that are used in multiple SCSs can be created as library projects and be copied to each SCS project.
Link Architecture View	A view on SCS Manager which graphically shows the resources of SCS project and data links among the resources. On this view, you can define POUs, add variable groups, etc. See Workbench User's Guide for more information.
Local variable	Variables that can be used in only one POU.
Logic simulation test	Tests performed by running a logic simulator from SCS Manager. The logic simulator is a program that simulates the behavior of POUs on a computer.
Logical data	For input variables, the data passed from an input variable to the application logic. For output variables, the data passed from the application logic to an output variable. For internal variables, the data to be output from that internal variable. Normally, the values of physical data and logical data match. However, while a variable is under forcing, the connection between its physical data and logical data is disconnected, and therefore they may not match.
Manual operation function block	Function blocks used to output values to the application logic by manual operation from CENTUM HIS when the system is integrated with CENTUM. These function blocks output either BOOL-type data or analog-type data and can be used for valve operation.
Mapping element/Mapping block	In a system integrated with CENTUM, a mapping element or mapping block is created if you assign a tag name to an internal variable, input/output variable, or a specific type of function block of the application logic using the Tag Name Builder. This scheme enables access to the data in SCS from CENTUM by specifying a tag name.
Master database	The database stored in SENG and is running on a target SCS. It consists of source files containing definitions for the SCS and the SCS database generated by running a build of the source files.
Master database offline download	The function to download, to the CPU modules of an SCS, the SCS database saved on SENG as the master database, which was previously downloaded to the SCS for actual run. You need to run this download when you replace both CPU modules in the SCS. You do not need to run this download when you replace one of the dual-redundant CPU modules.
Master Database Restoring function	This tool restores the SCS project being edited to the state it was last downloaded to the target SCS. It is used to discard the changes made to the work database so far and revert it to the master database as the new work database for engineering. This tool is helpful when you have accidentally changed any settings that require offline download.

Table Appendix 1-1 Terminologies used in User's Manual (Table continued)

Terminology	Meaning
Modbus Address Builder	The builder that is used to define Modbus device addresses for Modbus slave connection.
Modbus slave connection	Connection for communications where SCS acts as a Modbus slave and the data in the SCS are read or set by the Modbus master (external device) via Modbus protocol. This communication is called Modbus slave communication.
Modification files viewer	A viewer to view modification files saved in an operation history database.
Multi-Language Editor	The editor used to create and edit application logic for SCS. With the Multi-Language Editor, application logic can be created using the following three languages, which are defined in IEC 61131-3. • Function block diagram (FBD) • Ladder diagram (LD) • Structured Text (ST) See Workbench User's Guide for more information.
Narrowband system	CI Server integrated environment and FAST/TOOLS integrated environment that set the network mode of Vnet/IP-Upstream as narrowband mode.
Network mode	The operating mode of Vnet/IP-Upstream. A mode that supports the network characteristic can be selected from the following modes by using the Domain Property Setting Tool. • Standard mode • Wide-area mode • Narrowband mode
N-IO node	It is an SCSP3 component that consists of the N-IO I/O unit for inserting N-IO and the node interface unit.
Offline download	The function to download the system program of SCS and the database generated using the engineering functions of SENG to a target SCS while the CPU of the SCS is stopped. The SCS is restarted after the offline download is completed.
Online change download	The function to download only the changes made to the application to a target SCS while the CPU of the SCS is running. Online change download is not possible depending on which items of the application have been changed.
Online monitoring function	The function to monitor the application logic running on SCS. You can monitor the values of variables and function blocks of a running program and the status of whether conditions are met or not. The online monitoring function is available through the following windows: FBD window, LD window, and ST window of Multi-Language Editor, Dictionary View, and SPY List Window.
Operating mode	Operating mode of SCS. There are five operating modes: Stop mode, Loading mode, Initial mode, Waiting mode, and Running mode. SCS normally runs in the Running mode.
Operation history database viewer	A viewer to view operation log saved in an operation history database.

Continues on the next page

Table Appendix 1-1 Terminologies used in User's Manual (Table continued)

Terminology	Meaning
Operation history management	Functionality to record operations performed by each SENG user into the operation log. When downloading to SCS, the information of the modified project data (modification file) is saved. These operation log or change information are saved into the operation history database. CHS5170 Access Control and Operation History Management Package is required.
Operation history management setup tool	A tool to setup access control and operation history management functionality.
Operation mark	A frame-shaped mark attached to a faceplate displayed on CENTUM HIS.It is used to make certain elements or function blocks easy to be distinguished. You can save in SENG the operation marks set for elements or function blocks of SCS and download the saved operation marks to SCS.
Optical bus repeater	The device used to extend the distance of V net by using fiber-optic cable.
Optical ESB bus repeater module	Generic term for the modules mounted in nodes in SCS when nodes in the SCS are connected with fiber-optic cables for the purpose of extending the distance of ESB bus. Optical ESB bus repeater master modules can be mounted in CPU nodes or I/O nodes, while Optical ESB bus repeater slave modules can be mounted only in I/O nodes. A master module and a slave module are connected on a one-to-one basis using a fiber-optic cable.
Output disable status	The status of output modules in SCS in which the output values of the application logic are not output from the modules. Channels of all the output modules are in this status immediately after the SCS is started up. To enable outputs from the output modules in this status, it is necessary to perform the output enable operation. The output disable/enable status is controlled for each output channel.
Output enable operation	The operation to connect outputs from the application logic to the channels of output modules. You can perform this operation from the I/O Channels Status dialog box of SCS Maintenance Support Tool on SENG. This operation places all the channels of all the output modules on the SCS in the Output Enable status, and output values of the application logic are output from output channels. However, channels generating errors remain in the Output Disable status. Performing the output enable operation immediately after an SCS is started also initiates inter-SCS safety communication, SCS Link Transmission, and subsystem communication.
Output module	General term for the analog output module, the digital output module, and the universal type I/O module to which output channels are defined.
Output Shutoff Switch	A switch that shuts off the output of a module when a critical failure that can prevent normal output of signals has occurred with the analog output module and the digital output module. This switch can be activated automatically by setting the parameter for the output module.
Output value at fault	The value that is output as the fail-safe value when an output module detects an error.

Continues on the next page

Table Appendix 1-1 Terminologies used in User's Manual (Table continued)

Terminology	Meaning
Output variable	Variables connected to the channels of an output module, which are used in POUs.
Override	The operation to forcibly fix the value of a variable of SCS to a predefined value while the SCS is running normally. In order to enable override operations from CENTUM HIS, create application logic for performing override operation by using override function blocks.
%WB	An element of subsystem communication I/O
%WW	Communication I/O data area of subsystem communication
%XB	An element of safety subsystem communication I/O
%XW	Communication I/O data area of safety subsystem communication
Partial Stroke Test (PST)	Inspection of emergency shutdown valves, which do not need to work in normal conditions. PST is performed by slightly moving the valve to check if the valve is not stuck at one position and that it can work properly when required.
Physical data	For input variables, the data read from an input module. For output variables, the data to be set into an output module. For internal variables, the data input to the variable. Normally, the values of physical data and logical data match. However, while a variable is under forcing, the connection between its physical data and logical data is disconnected, and therefore they may not match.
Plant Resource Manager (PRM)	A software product of Yokogawa that is used to manage field devices and other equipment used in a plant online.
Primary channel	A channel that can set high current output function for several DO together in analog digital I/O module. A channel with the smallest number among several DO used together
Process data	In ProSafe-RS, process data means analog input/output data and discrete input/output data.
Producer SCS	SCS which sends data in inter-SCS safety communication.
Program Organization Unit (POU)	Generic term for program, function block, and function that are defined in IEC 61131-3.
Project Attribute Tool	The tool that shows the attributes of SCS projects. It is mainly used when using test functions.
Project comparing tool	A tool to detect differences between two SCS projects, display and print them. This tool is able to compare work database and the master database of any SCS project.
ProSafe authentication mode	A user authentication mode to provide separate user management for ProSafe-RS users apart from Windows users when using access control and operation history management functionality.
ProSafe-RS	Safety Instrumented System that meets SIL 3 of the Safety Integrity Level (SIL) defined by IEC 61508. Product components of ProSafe-RS Lite are also included.

Continues on the next page

Table Appendix 1-1 Terminologies used in User's Manual (Table continued)

Terminology	Meaning
ProSafe-RS I/O file	An xslx format file that contains the safety I/O list, safety communication I/O list and I/O module information, which is stored in the ADMDB. You can create this file for each SCS project. You import it to iDefine.
ProSafe-RS Lite	Safety Instrumented System that meets SIL 2 of the Safety Integrity Level (SIL) defined by IEC 61508.
ProSafe-SLS	Safety Instrumented System that meets SIL 4 of the Safety Integrity Level (SIL) defined by IEC 61508.
RAS function	RAS means Reliability, Availability, and Serviceability. This is an important standard when evaluating the system performance. Reliability indicates robustness against error occurrence, availability indicates shortness of downtime and serviceability indicates ease of repair at failure. The RAS function diagnoses whether hardware and software of SCS are running normally and handles maintenance of them if any errors are detected. It is one of the most essential SCS functions which shuts down the system, changes the status of SCS, and takes other actions according to the situation.
Resource	A set of application logic that is defined for a single SCS.
RS Project	A group of SCS projects that is defined in order to manage engineering data of multiple SCS projects together. The status of SCSs belonging to the same RS project can be monitored collectively by using the SCS Maintenance Support Tools.
Safety application	Application which monitors the safety status of the plant and, if any abnormality is detected, performs the safety action that is programmed for the abnormality.
Safety Control Station (SCS)	A station which performs safety control in ProSafe-RS systems. SCS consists of a CPU node and I/O nodes.
Safety Control Unit	The name of the hardware of a component of SCS on which CPU modules are mounted. Abbreviated as SCU. Also referred to as the CPU node.
Safety Engineering Station (SENG)	A computer installed with the SCS engineering functions, test functions, and maintenance functions. On SENG, you can perform engineering works, such as creation, downloading, and testing of the application logic, and maintenance of SCS.
Safety Node Unit	The name of the hardware of a component of SCS on which modules for the FIO other than the CPU modules are mounted. Abbreviated as SNU. Also referred to as the I/O node.
Safety subsystem communication	This function is used for safe communication between SCS of ProSafe-RS and its subsystems, with the SCS acting as the master.
Scan period of the application logic execution function	Of the two types of scan periods of SCS, the scan period at which the application logic execution functions are executed. It is defined by setting the [Cycle Timing] in the Resource Properties dialog box of SCS Manager.

Continues on the next page

Table Appendix 1-1 Terminologies used in User's Manual (Table continued)

Terminology	Meaning
Scan period of the external communication function	Of the two types of scan periods of SCS, the scan period at which the external communication functions are executed. This scan period is defined by setting [Scan Period for External System] on the SCS Constants Builder.
SCS Constants Builder	The builder used to set the constants and the mode of time synchronization of an SCS.
SCS database	Database in a format executable on SCS, which stores the results of engineering works done on SENG. SCS database consists of POU DB, Variable DB, System DB, and Integration DB.
SCS global switch communication	An interference-free type of SCS link transmission that is used to communicate with CENTUM FCS.
SCS Information dialog	The dialog box which shows the numbers of the POUs and variables used in the SCS project or the size of the area for storing them. It is a dialog box of the SCS Maintenance Support Tool.
SCS link transmission	The function of SCS that a local SCS broadcasts its data periodically to other stations within the domain. By using this function, a local SCS can also receive the data broadcasted by other stations and the received data can be referenced by the application logic. SCS link transmission is available in two modes: SCS link transmission safety communication and SCS global switch communication.
SCS Link Transmission Builder	The builder used to define SCS link transmission safety communication and SCS global switch communication.
SCS Link Transmission Lock Window	The window used to lock/unlock the data for SCS link transmission on an SCS by SCS basis. You can set values to the SCS link transmission communication data of the SCS locked through this window. This window is used on SENG for maintenance and testing purposes.
SCS link transmission safety communication	A type of SCS link transmission that can implement safety loops.
SCS Maintenance Support Tool	A set of tools to facilitate maintenance of SCS. These tools are for supporting maintenance tasks and analysis to find out the cause of errors, not provided for the monitoring of SCS by the operator.
SCS Manager	The main window used to define SCS projects. It is also called "Workbench."
SCS Project	A project database corresponding to a single SCS. In ProSafe-RS, engineering data are managed for each SCS project. Within an SCS project, the database consists of master database and work database, which are managed separately.
SCS project attribute	Attributes given to SCS projects for the testing of SCS. You can specify one of three attributes: default project, current project, and user-defined project. The project attribute determines whether the project can be downloaded to a target SCS, whether the project can be tested by SCS simulation, etc.

Continues on the next page

Table Appendix 1-1 Terminologies used in User's Manual (Table continued)

Terminology	Meaning
SCS Project Properties	This is the title of the dialog box on SCS Manager that is used to define SCS properties such as the model name, domain number, and station number. When the system is integrated with CENTUM, the location of CENTUM project folder is also defined in this dialog box. See Workbench User's Guide for more information.
SCS security level	The numeric value which shows the degree of how the data in the SCS is protected against data setting access from external devices or by personnel. The security levels are 0, 1, or 2, and SCS usually runs at level 2, which is the highest level. Level 0 is called the offline level, and levels 1 and 2 are called the online level.
SCS simulation test	Testing with SCS Simulators. SCS simulator is a program to simulate SCS actions on a computer.
SCS taglist generation	The function to generate an SCS taglist, which is required for monitoring SCS from CENTUM HIS. SCS taglist generation is run by selecting the [SCS Taglist Import] command on System View of CENTUM. SCS taglist is a database that is defined based on the tag names assigned to function blocks and other elements of SCS.
SCS Test Function Window	A window which manages starting and quitting of SCS simulator. You can start this window from SCS Manager or System View of CENTUM.
SCSL2-S (SCSL2)	SCS which uses L1SC70S/L1SC70D as the CPU node.
SCSP1-S (SCSP1)	SCS which uses SSC50S/SSC50D as the CPU node.
SCSP2-S (SCSP2)	SCS which uses SSC60S/SSC60D as the CPU node.
SCSP3-S (SCSP3)	SCS that uses S2SC70S/S2SC70D as the CPU node.
SCSV1-S (SCSV1)	SCS which uses SSC10S/SSC10D as the CPU node.
SCSU1-S (SCSU1)	SCS which uses SSC57S/SSC57D as the CPU node.
Self document	A function of SENG which prints out the definitions of SCS projects in certain formats.
Self-diagnosis	The schema of SCS for detecting abnormality in hardware and software by itself. It is run periodically and if any abnormality is detected, a diagnostic information message and status information are generated. The diagnostic information messages are sent to SENG and CENTUM HIS. The status information can be referenced by the application logic.
Sequence of Event Recorder (SOER)	A function that records events detected by SCS so that the user can analyze them. The collected and saved event information can be shown on the SOE viewer of SENG or CENTUM HIS.
Serial communication module	The name of a module that supports Modbus communication protocol (RTU mode). SCS uses this module to perform subsystem communication or Modbus slave communication.

Continues on the next page

Table Appendix 1-1 Terminologies used in User's Manual (Table continued)

Terminology	Meaning
Stand-alone ProSafe-RS system	The ProSafe-RS system that is not integrated with the CENTUM system ,CI Server system, nor FAST/TOOLS system. The following cases apply to this system: • Stand-alone SCS configuration • When temporarily separated from the CENTUM system , CI Server system, or FAST/TOOLS system during engineering (including when the CENTUM system , CI Server system, or FAST/TOOLS system is finally integrated) • Including when connected to PRM or STARDOM
Stand-alone SCS configuration	A system configuration where an SCS which is connectable to Vnet/IP network runs alone without being connected on Vnet/IP network.
Standard model	A model of IT security settings set on SENG. The standard model is categorized into two types according to the management of computers on the Windows network: Windows domain type and stand-alone type.
Start output module operation	The operation to recover the outputs of a module that were shut off by the activation of the output shut-off switch. This operation is performed using the SCS maintenance support tool. After recovery, all the channels of the output module are in the output disable status, so the output enable operation is required to deliver outputs.
Signal category	Classification of AI/AO/DI/DO
Structured Text (ST)	A language defined in IEC 61131-3.
Subsystem communication	Communications performed between SCS and a subsystem. In this communication, SCS acts as the communication master and reads/writes data from/to the subsystem. Modbus protocol is supported in subsystem communication.
Subsystem communication module	Another name of serial communication module. This name is used when the serial communication module is used for subsystem communication.
System function block	Function blocks which indicate the status of SCS. System function blocks have a name beginning with "SYS_."
System View	The main window of the system generating functions of CENTUM. System View plays a central part in CENTUM engineering works.
Tag Name Builder	The builder used to define tag names for function blocks and variables for use in a system integrated with CENTUM. Annunciator messages are also defined on this builder. By defining tag names using this builder, their mapping blocks or elements are created.
Target test	Testing of created application on an actual SCS by using the test functions.
Test Project Creating Tool	The tool used to create projects for SCS simulation test.

Continues on the next page

Table Appendix 1-1 Terminologies used in User's Manual (Table continued)

Terminology	Meaning
Time synchronization method	Method of system time synchronization. For SCSV, V net time synchronization or IRIG-B time synchronization can be selected. For SCSP, only Vnet/IP time synchronization is used. • V net time synchronization: The V net time is set to the CPU modules and input modules of the SCS. • IRIG-B time synchronization: Time information is acquired via IRIG-B from the standard clock installed outside the system and set to the CPU modules and input modules of the SCS. • Vnet/IP time synchronization: The network time on Vnet/IP is set to the CPU modules and input modules of the SCS.
Trip signal file	A file on SCS that stores the SOE data of the event specified as the trip signal and the data of the events before and after that event. This file can be saved into SENG. The signals that can be specified as trip events are the signals of DI/DO modules and the signals of function blocks dedicated to SOE.
Universal type I/O module	General term for the modules that can switch signal category of I/O module channels by software setting
Unit for optical ESB bus repeater module	A unit which is connected to SCS and exclusively used for mounting ESB bus optical repeater modules.
User-defined function	Functions defined by the user. You can create user-defined functions by using Multi Language Editor.
User-defined function block	Function blocks defined by the user. You can create user-defined function blocks by using Multi Language Editor.
User-defined project	A project created using Test Project Creating Tool. This project is for SCS simulation tests and cannot be downloaded to actual SCS.
Vnet/IP device	The device that is connected with Vnet/IP. Vnet/IP interface card (model: VI702) and processor module (model: SCP451, SCP461, S2CP471, and L1CP471) are included.
V net bus repeater	The device used to extend the distance of V net bus coaxial cable.
V net router	The device used to connect a V net domain and a Vnet/IP domain. Engineering of V net router is done on the CENTUM system.
Version Control Tool	A function that manages the change history of SCS projects and assists the user with system updating tasks. By using the Version control tool, you can save the SCS project data at a certain point with a version number and restore the project data of a certain version.
Virtual domain link transmission	Virtual domain link transmission provides virtual domain capability to V net domain and Vnet/IP domain connected with V net router style S3 or above. SCS global switch communications are allowed between SCS and FCS in the virtual domain and these communications are called virtual domain link transmission.
Vnet/IP interface card	An interface card installed to a PC to allow it connecting to Vnet/IP network.

Continues on the next page

Table Appendix 1-1 Terminologies used in User's Manual (Table continued)

Terminology	Meaning
Vnet/IP open communication driver	A driver software on a PC necessary to perform open communications (Ethernet communications) on Vnet/IP network.
Watch Dog Timer (WDT)	A mechanism which allows a system to self-diagnose to check if it is running normally at a constant period. SCS also has a WDT.
Windows authentication mode	A user authentication mode to manage a ProSafe-RS user as a Windows user when using access control and operation history management functionality.
Wiring check adapter	An element used to detect faults in the wiring between discrete input modules and field devices. Two types of wiring check adapters are available: SCB100 for detecting disconnections and SCB110 for detecting short-circuits.
Work database	The results of engineering are first saved in a work database. A work database consists of source files containing definitions for the SCS and the SCS database generated by running a build of the source files.
Workbench	Another name of SCS Manager. Workbench User's Guide is the help file that explains the development environment of SCS application. You can read Workbench User's Guide while you perform engineering works in the development environment called up from SCS Manager. (However, Workbench User's Guide does not include explanations about the tools started from the launchers selected in the [Tools] menu of SCS Manager.)

Appendix 2. List of links

This section provides information and links to the operation that are required in using the ProSafe-RS software and hardware in each typical scene.

- To know the type of the SCS hardware
- To know the function of the SCS software
- To know what type of software can be used in SENG
- To know the functions and precautions when using SENG on the virtualization platform
- To know the function of the tool that are included in the SCS Maintenance Support Tool
- When wanting to know the operation in an emergency.
- To know the procedures and precautions of online change download
- To replace the ProSafe-RS equipment
- When wanting to know about connections with other systems.

Information on the types of SCS hardware

Information on the types of SCS hardware is as follows.

SEE ALSO

For more information about types of the safety control unit, refer to:

■ Information on procedures and precautions of online change download

Information on procedures and precautions of online change download is as follows.

SEE ALSO For more information about how to run an online change download, refer to:

E1.1, “Online change download” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about procedures for online change of an application, refer to:

E1.2, “Entire procedure of online change of application” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about online change downloadable items, refer to:

E1.3, “List of applicable items for online change” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about precautions when performing an online change of an application, refer to:

E1.5, “Precautions for online change” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about precautions when performing an online change download with the N-IO node, refer to:

E1.6, “Precautions for online change download of N-IO” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about online changes with subsystem communication, refer to:

E1.7, “Online change of subsystem communication modules” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Information on tasks for replacing ProSafe-RS equipment

Information on tasks for replacing ProSafe-RS equipment is as follows.

SEE ALSO For more information about precautions when replacing ProSafe-RS equipment, refer to:

I1.2, “Maintenance for ProSafe-RS equipment” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about precautions and procedures for performing hardware maintenance, refer to:

E., “Maintaining the SCS” in Hardware User's Guide (IM 32P06C10-01EN)

Information on connections with other systems

Information on connections with other systems is as follows.

SEE ALSO For more information about integration with CENTUM, refer to:

B., “CENTUM integration” in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

For more information about integration with CI Server, refer to:

A., “Integration with CI Server function” in Integration with CI Server (IM 32P04D20-01EN)

For more information about connecting with ProSafe-SLS, refer to:

D4., “ProSafe-SLS communication (for ALR121)” in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

For more information about connecting with other YOKOGAWA software, refer to:

D., “Connection with Other Products” in Installation Guide (IM 32P01C50-01EN)

Revision information

Title : ProSafe-RS User's Guide

Manual No. : IM 32P01B10-01EN

Dec. 2023/11th Edition/R4.10 or later

A1.1, A1.2, A7.3.1	Added descriptions of Windows Server 2022.
A1.1, A1.2	Deleted descriptions of Windows Server 2012 R2.
A1.2	Changed the version of .NET Framework.
A1.2	Updated software version descriptions in "● Software that can coexist with ProSafe-RS," "■ CENTUM integration system," "■ CI Server integration system," "■ FAST/TOOLS integration system," "■ Use of iDefine," "■ Use of PRM," "■ Use of Exaopc," and "■ Use of Exaquantum."

Jun. 2023/10th Edition/R4.09

A1.2	Updated software version descriptions in "● Software that can coexist with ProSafe-RS," "■ CENTUM integration system," "■ CI Server integration system," "■ FAST/TOOLS integration system," "■ Use of iDefine," "■ Use of PRM," "■ Use of Exaopc," and "■ Use of Exaquantum."

Nov. 2022/9th Edition/R4.08

A1.2	Added descriptions of Windows Server IoT 2019 Standard.
A1.2	Updated software version descriptions in "● Software that can coexist with ProSafe-RS," "■ CENTUM integration system," "■ CI Server integration system," "■ FAST/TOOLS integration system," "■ Use of iDefine," "■ Use of PRM," "■ Use of Exaopc," and "■ Use of Exaquantum."

Jan. 2022/8th Edition/R4.07

A1.1, A1.2, A7.3.1	Added descriptions of Windows Server 2019.
A1.2	Updated software version descriptions in "● Software that can coexist with ProSafe-RS," "■ CENTUM integration system," "■ CI Server integration system," "■ FAST/TOOLS integration system," "■ Use of iDefine," "■ Use of PRM," "■ Use of Exaopc," and "■ Use of Exaquantum."
A7.2.1	Added descriptions of replication.
A7.4.2	Updated descriptions of resources required for a virtual machine and precautions when connecting remote desktop.

Feb. 2021/7th Edition/R4.06

Introduction, A7.4.1, Appendix1, 2	Updated FAST/TOOLS to CI Server.
A	Added descriptions about ProSafe-RS Lite.
A1.1, A1.2	Deleted descriptions about unsupported OS and added descriptions about supported OS.
A1.2	Updated software version descriptions in "● Software that can coexist with ProSafe-RS," "■ CENTUM integration system," "■ FAST/TOOLS integration system," "■ Use of iDefine," "■ Use of PRM," "■ Use of Exaopc," and "■ Use of Exaquantum", added CI Server integration system.
A2	Added a system configuration of ProSafe-RS.

Appendix 1	Added CI Server, iDefine for ProSafe-RS, ProSafe-RS, ProSafe-RS Lite, ProSafe-SLS, and SCSL2-S (SCSL2) in the glossary.

Dec. 2019/6th Edition/R4.05

Introduction	Updated description of registered trademarks and trademarks
A1.1, A5, A5.1, A6.4.2, B1	Added description of Forced I/O Viewer function
A1.2	Updated software version descriptions in "● Software that can coexist with ProSafe-RS," "■ CENTUM integration system," "■ FAST/TOOLS integration system," "■ Use of iDefine," "■ Use of PRM," "■ Use of Exaopc," and "■ Use of Exaquantum."
Appendix 1	Added Forced I/O Viewer function, and stand-alone ProSafe-RS system in the glossary.

Aug. 2018/5th Edition/R4.04

Introduction	Updated description of registered trademarks of YOKOGAWA.
A1.1, A1.2	Added descriptions of Windows Server 2016.
A1.2	Updated descriptions of .NET Framework.
A1.2	Updated software version descriptions in "● Software that can coexist with ProSafe-RS," "■ CENTUM integration system," "■ FAST/TOOLS integration system," "■ Use of iDefine," "■ Use of PRM," "■ Use of Exaopc," and "■ Use of Exaquantum."
A6	Added new section on virtualization platform.

Oct. 2017/4th Edition/R4.03.10

A1.2	Changed version number and added version description in CENTUM integration system, FAST/TOOLS integration system, use of iDefine, use of PRM, use of Exaopc and use of Exaquantum.
A2, A2.3.1	Added Safety Subsystem communication related descriptions.
A2.3.1, A2.4.1	Added description about Fire and Gas communication module.
A3, A4, B1	Added Safety subsystem communication engineering related descriptions.
Appendix 1	Added Field network, Field wireless backbone network, Field wireless network, Field wireless system, Fire and gas communication, %WB, %WW, %XB, %XW and safety subsystem communication in the glossary.

May 2017/3rd Edition/R4.03

Introduction	Deleted Windows Vista from "■ Trademark Acknowledgments."
A1.1, A1.2	Added descriptions of Windows 10 and deleted descriptions of Windows Vista and Windows Server 2008.
A1.2	Changed software versions, descriptions of ProSafe-RS functions and CENTUM release number, descriptions of coexistence of ProSafe-RS and CENTUM on the same computer, descriptions of whether or not ProSafe and iDefine can coexist on the same computer, and descriptions of versions.

Oct. 2016/2nd Edition/R4.02

Entire manual	Changed the symbols that indicate warning and caution.
Introduction	Updated descriptions in "■ Safety, Protection, and Modification of the Product," "■ Symbols," and "■ Trademark Acknowledgments." Added a new term in "■ Full Names and Simplified Terms."
A1.2	Updated software version numbers in "● Supported OS," "● Software that can coexist with ProSafe-RS," "■ CENTUM integration system," "■ FAST/TOOLS integration system," "■ Use of PRM," and "■ Use of Exaopc."

A1.2, A3, B1	Added iDefine related descriptions.
Appendix 1	Added iDefine-config file, iDefine Test Manager, and ProSafe-RS I/O file to the glossary.

Dec. 2015/1st Edition/R4.01

Engineering Guide Vol. 1

IM 32P01C10-01EN

YOKOGAWA
Yokogawa Electric Corporation

IM 32P01C10-01EN
11th Edition

Introduction

This manual is the engineering guide of ProSafe-RS.

This document explains an overview of ProSafe-RS functions and the cautionary notes which needs to be considered for engineering, based on the basic flow of engineering such as design, manufacturing, operation and maintenance of a safety equipment system by using ProSafe-RS.

Please refer to the Engineering Guide Vol.2 for the steps and precautions to take for creating application logic using ProSafe-RS engineering.

See the Appendix in the ProSafe-RS User Guide for the terminology in the descriptions of ProSafe-RS.

Notes and precautions regarding SCSP1 described in this document also apply to SCSU1.

CI Server Integration also contains FAST/TOOLS Integration function. If FAST/TOOLS Integration is used, replace the term “CI Server” with “FAST/TOOLS” in the user’s manual.

If you are using the Field Commissioning Support Package, replace “FieldMate Validator” in the User's Manual with “Field Commissioning Support Package.”

If you are using YFGW520, replace the term “YFGW510” with “YFGW520” in the User’s Manual.

This document is composed of the following parts.

- Part A Specifications and functions that are needed to design applications
  This part describes the specifications and functions that are needed to design a ProSafe-RS application. It describes the control bus, system time synchronization, and the engineering specifications and functions with a focus on ProSafe-RS and Control Station.
- Part B Designing applications
  This part describes the main points of the design specifications of ProSafe-RS systems.
- Part C Basics of creating applications
  This part describes the common work flow, precautions and common procedures to create a ProSafe-RS application.
- Part D Procedures to create applications using the I/O list engineering method
  This part gives an overview of the procedures of the automated design organizer when using I/O list engineering and the procedures when using iDefine.
- Part E Changing applications
  This part describes the steps to change applications online, the function that can export the application data to external folder and import the exported external file.
- Part F Installation and start-up
  This part explains the installation of ProSafe-RS system, the connection to field devices, a procedure of start-up including tests, commissioning and precautions for the start-up.
- Part G Emergency procedures
  This part describes the actions to be taken in an emergency situation during plant operation, behavior of SCS at error occurrence, and recovery procedures.
- Part H Monitoring the status of SCS
  This part describes the management of the SCS status. It explains the method to view the SCS status registered in RS projects, the detailed status of the specified SCS, and the detailed status of I/O module by using the IOM Report. It also mentions how to verify the diagnostic information message that is generated in the SCS.
- Part I Maintenance
  This part explains cautionary points and steps to maintain ProSafe-RS devices (such as I/O modules) and field devices.
- Appendix

11th Edition : Dec. 2023 (YK)
All Rights Reserved. Copyright © 2015, Yokogawa Electric Corporation

This part describes the setting items of nodes, modules and channels, RS original engineering, cautionary points and maintenance of ProSafe-RS prior to R4, and maintenance of sales discontinued products.

Safety Precautions for Use

Safety, Protection, and Modification of the Product

- To protect the system controlled by the Product and the Product itself and to ensure safe operation, please observe the safety precautions described in this Manual. Yokogawa Electric Corporation ("YOKOGAWA") assumes no liability for safety if users fail to observe the safety precautions and instructions when operating the Product.
- If the Product is used in a manner not specified in the User's Manuals, the protection provided by the Product may be impaired.
- If any protection or safety circuit is required for the system controlled by the Product or for the Product itself, please install it externally.
- Be sure to confirm the specifications and required settings of the devices that are used in combination with the Product by referring to the instruction manual or other documents of the devices.
- Use only spare parts that are approved by YOKOGAWA when replacing parts or consumables of the Product.
- Do not use the Product and its accessories such as power cords on devices that are not approved by YOKOGAWA. Do not use the Product and its accessories for any purpose other than those intended by YOKOGAWA.
- Modification of the Product is strictly prohibited.
- The following symbols are used in the Product and User's Manuals to indicate the accompanying safety precautions:

Indicates that caution is required. This symbol for the Product indicates the possibility of dangers such as electric shock on personnel and equipment, and also indicates that the user must refer to the User’s Manuals for necessary actions. In the User’s Manuals, this symbol is used together with a word “CAUTION” or “WARNING” at the locations where precautions for avoiding dangers are described.

<French> Signale qu’il faut faire preuve de prudence. Ce symbole pour le produit signale la possibilité d’un danger pour le personnel et l’équipement comme un choc électrique, et signale également que l’utilisateur doit se référer au Manuel de l’utilisateur afin de prendre les mesures nécessaires. Dans le Manuel de l’utilisateur, ce symbole est utilisé conjointement avec la mention «CAUTION» ou «WARNING» aux endroits où sont décrites les précautions pour éviter les dangers.

Indicates that caution is required for hot surface. Note that the devices with this symbol become hot. The risk of burn injury or some damages exists if the devices are touched or contacted.

<French> Signale qu'il faut faire preuve de prudence avec la surface brûlante. Les appareils sur lesquels est apposé ce symbole risquent de devenir brûlants. Tout contact physique ou matériel avec ces appareils risque de provoquer des brûlures ou des dommages.

Identifies a protective conductor terminal. Before using the Product, you must ground the protective conductor terminal to avoid electric shock.

Identifies a functional grounding terminal. A terminal marked "FG" also has the same function. This terminal is used for grounding other than protective grounding. Before using the Product, you must ground this terminal.

~ Indicates an AC supply.

⎓ Indicates a DC supply.

| Indicates that a component such as a power supply switch is turned ON.

○ Indicates that a component such as a power supply switch is turned OFF.

Notes on Handling User's Manuals

- Hand over the User's Manuals to your end users so that they can keep the User's Manuals on hand for convenient reference.
- Thoroughly read and understand the information in the User's Manuals before using the Product.
- For the avoidance of doubt, the purpose of the User's Manuals is not to warrant that the Product is suitable for any particular purpose but to describe the functional details of the Product.
- Contents of the User's Manuals are subject to change without notice.
- Every effort has been made to ensure the accuracy of contents in the User's Manuals. However, should you have any questions or find any errors, contact us or your local distributor. The User's Manuals with unordered or missing pages will be replaced.

Warning and Disclaimer

- Except as specified in the warranty terms, YOKOGAWA shall not provide any warranty for the Product.
- YOKOGAWA shall not be liable for any indirect or consequential loss incurred by either using or not being able to use the Product.

Notes on Software

- YOKOGAWA makes no warranties, either expressed or implied, with respect to the Software Product's merchantability or suitability for any particular purpose, except as specified in the warranty terms.
- Purchase the appropriate number of licenses of the Software Product according to the number of computers to be used.
- No copy of the Software Product may be made for any purpose other than backup; otherwise, it is deemed as an infringement of YOKOGAWA's Intellectual Property rights.
- Keep the software medium of the Software Product in a safe place.
- No reverse engineering, reverse compiling, reverse assembling, or converting the Software Product to human-readable format may be performed for the Software Product.
- No part of the Software Product may be transferred, converted, or sublet for use by any third-party, without prior written consent from YOKOGAWA.

Documentation Conventions

Symbols

The following symbols are used in the User's Manuals.

 WARNING	Indicates precautions to avoid a danger that may lead to death or severe injury.
 CAUTION	Indicates precautions to avoid a danger that may lead to minor or moderate injury or property damage.
IMPORTANT	Indicates important information required to understand operations or functions.
TIP	Indicates additional information.
	Indicates referenced content. In online manuals, you can view the referenced content by clicking the links that are in green text. However, this action does not apply to the links that are in black text.

Typographical Conventions

The following typographical conventions are used throughout the User's Manuals.

Commonly Used Conventions throughout the User's Manuals

- Δ Mark
  Indicates that a space must be entered between character strings.
  Example:

  ```
  .ALΔPIC010Δ-SC
  ```

- Character string enclosed by braces { }
  Indicates character strings that may be omitted.

  Example:

  ```
  .PRΔTAG{Δ.sheet name}
  ```

Conventions Used to Show Key or Button Operations

- Characters enclosed by brackets [ ]
  When characters are enclosed by brackets in the description of a key or button operation, it indicates a key on the keyboard, a button name in a window, or an item in a list box displayed in a window.

  Example:

  To alter the function, press the [ESC] key.

Conventions of a User-defined Folder

- User-defined folder name enclosed by parenthesis ( )
  User definable path is written in a pair of parentheses.

  Example:

  ```
  (RS Project Folder)\SCS0101
  ```

If the RS Project Folder is `C:\MYRSPJT`, the above path becomes `C:\MYRSPJTSCS0101`.

Drawing Conventions

Drawings used in the User's Manuals may be partially emphasized, simplified, or omitted for the convenience of description.

Drawings of windows may be slightly different from the actual screenshots with different settings or fonts. The difference does not hamper the understanding of basic functionalities and operation and monitoring tasks.

Explanation of Hardware and Software Behaviors in the User's Manuals

In the User's Manuals, system behaviors are explained assuming that the latest versions of YOKOGAWA software and hardware at the time of publication of the User's Manuals are installed.
If additional precise information about the safety of legacy versions of software or hardware is required, a link to the corresponding explanation is provided. Please refer to the information according to your system.

Definitions of Node and Module Terms

In the User's Manuals, nodes and modules are referred to by using collective terms, another terms, or abbreviations based on the following definitions:

- Definitions of nodes
  - Node: A node is a collective term for an FIO node and an N-IO node.
  - FIO node: This is a collective term for a safety control unit, a safety node unit, and a unit for optical ESB bus repeater module.
  - CPU node: This is another term for a safety control unit. The abbreviation of safety control unit is SCU.
  - I/O node: This is another term for a safety node unit. The abbreviation of safety node unit is SNU.
  - N-IO node: This is a collective term for a node interface unit and an N-IO I/O unit. The abbreviation of node interface unit is NIU.
- Definitions of modules
  - I/O module: This is a collective term for an FIO I/O module and an N-IO I/O module.
  - FIO I/O module: This is a collective term for an analog I/O module and a digital I/O module for FIO, and a communication module.
  - N-IO I/O module: This is a collective term for the modules that can be mounted on an N-IO I/O unit.
  - AIO/DIO module: This is a collective term for an analog I/O module, a digital I/O module, and a universal type I/O module.
  - Analog I/O module: This is a collective term for an analog input module and an analog output module.
  - Digital I/O module: This is a collective term for a digital input module and a digital output module.
  - Universal type I/O module: This is a collective term for the I/O modules for which the channel signal category can be changed by software.

- Input module: This is a collective term for an analog input module, digital input module, and a universal type I/O module with defined input channels.
- Output module: This is a collective term for an analog output module, digital output module, and a universal type I/O module with defined output channels.
- Communication module: This is a collective term for a serial communication module, an Ethernet communication module, and a fire and gas communication module.

Full Names and Simplified Terms

In the User's Manuals, simplified terms listed in the following table are used.

Table Info-1 Full Names and Simplified Terms

Full Name	Simplified Term
Automation Design Suite	AD Suite
Automation Design Organizer	AD Organizer
Automation Design Server	AD Server
Automation Design project	AD project
Automation Design Master Database	ADMDB
Automation Design Suite Administration Tool	ADS Administration Tool
iDefine for ProSafe-RS	iDefine
Modification Package	ModPack
SCSV1-S (SCS supporting the SSC10S/SSC10D safety control units)	SCSV1
SCSP1-S (SCS supporting the SSC50S/SSC50D safety control units)	SCSP1
SCSP2-S (SCS supporting the SSC60S/SSC60D safety control units)	SCSP2
SCSP3-S (SCS supporting the S2SC70S/S2SC70D safety control units)	SCSP3
SCSL2-S (SCS supporting the L1SC70S/L1SC70D safety control units)	SCSL2
SCSU1-S (SCS supporting the SSC57S/SSC57D safety control units)	SCSU1

Copyright and Trademark Notices

All Rights Reserved

The copyright of the programs and online manuals contained in the software medium of the Software Product shall remain with YOKOGAWA.

You are allowed to print the required pages of the online manuals for the purposes of using or operating the Product; however, reprinting or reproducing the entire document is strictly prohibited by the Copyright Law.

Except as stated above, no part of the online manuals may be reproduced, transferred, sold, or distributed to a third party in any manner (either in electronic or written form including, without limitation, in the forms of paper documents, electronic media, and transmission via the network). Nor it may be registered or recorded in the media such as films without permission.

A. Specifications and functions that are needed to design applications

This part describes the following specifications and functions that are needed to design a ProSafe-RS application:

- Vnet/IP network
- Security of ProSafe-RS
- Time synchronization
- SCS software configuration, hardware, I/O, performance and scan period, RAS, and application capacity
- Safety system generation function

Read this to understand the specifications and functions when engineering or doing the feasibility study prior to designing.

SEE ALSO

For more information about the engineering method differs for each engineering tool used guidelines for selecting an engineering method, refer to:

"■ Guidelines for selecting an engineering method" on page A10-2

A1. Overview of Vnet/IP network

Vnet/IP is a control communication network that is used in ProSafe-RS systems that conform to the IEEE802.3 standards. It is a highly reliable network built in dual-redundant configurations.

Vnet/IP supports 1 Gbps or 100 Mbps transmission speed.

A Vnet/IP network is built by using network devices such as Layer 2 switches and Layer 3 switches, and transmission media such as UTP (Unshield Twist Pair) cables and optical fiber cables.

Communication paths of control communication

A Vet/IP network is a redundant network for control communication. In Vnet/IP, redundant buses are configured with independent subnets of bus 1 and bus 2.

Control communication is the communication for transferring control data.

Normally, bus 1 is used for control communication. When bus 1 fails due to a communication error, control communication is continued on bus 2.

An Ethernet network apart from the Vnet/IP is used for file transfer and data communication except for control communication.

Connecting Ethernet devices

Ethernet devices that do not use control communication are connected to an Ethernet network that was installed separately from the Vnet/IP.

SEE ALSO For more information about the Vnet/IP- Upstream network used in CI Server integration, refer to:

A., “Integration with CI Server function” in Integration with CI Server (IM 32P04D20-01EN)

A1.1 Vnet/IP network system configuration

This section describes the system configuration and components of the Vnet/IP network.

Vnet/IP network system configuration

The following figure shows an example of the Vnet/IP network system configuration.

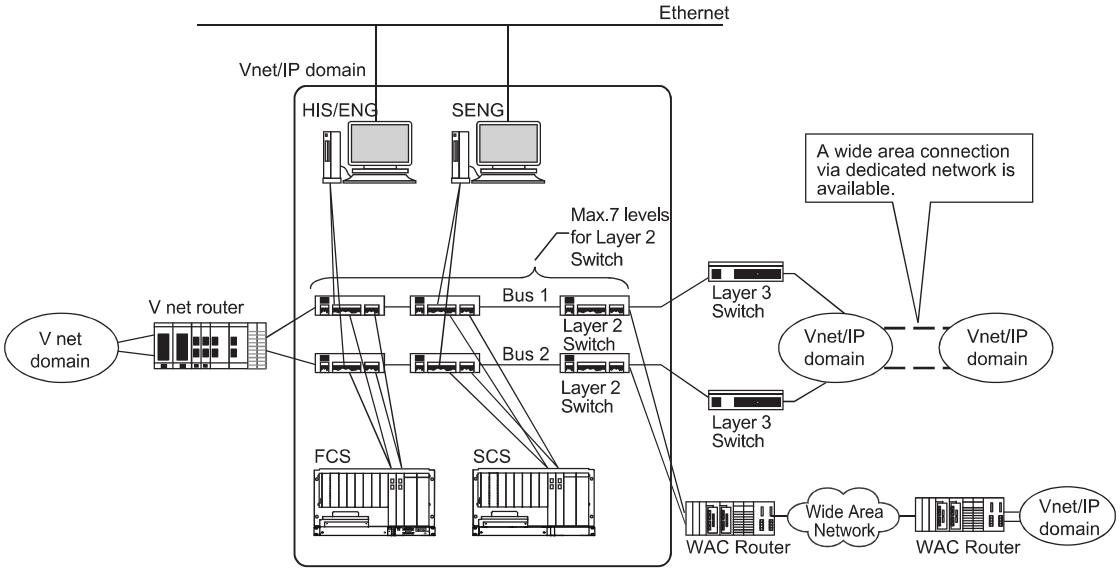

Figure A1.1-1 System components of a Vnet/IP network

SENG and HIS set up in the virtual machine on the virtualization platform are also connected to the Vnet/IP network.

SEE ALSO

For more information about system structure example on virtualization platform, refer to:

A7.2, “System configuration of virtualization platform” in ProSafe-RS User’s Guide (IM 32P01B10-01EN)

For more information about precautions related to Vnet/IP communication on the virtualization platform, refer to:

A7.4.1, “Precautions related to Vnet/IP communication on the virtualization platform” in ProSafe-RS User’s Guide (IM 32P01B10-01EN)

Components of Vnet/IP network

The components of the Vnet/IP network are as follows:

Vnet/IP station

A Vnet/IP device equipped station that is connected to a Vnet/IP network is referred to as a Vnet/IP station. A Vnet/IP station in a domain is connected to Layer 2 switches provided one for each bus. Vnet/IP stations are described below.

- Safety Engineering Station (SENG)
  SENG is a computer for ProSafe-RS engineering and maintenance. It is connected to a Vnet/IP network through a Vnet/IP interface card installed in the computer. The Vnet/IP interface card has two ports and each port is connected to a transmission cable for Vnet/IP to support redundant Vnet/IP buses.
- Safety Control Station (SCS)
  SCS is a station for ProSafe-RS safety control. The transmission speed of an SCS that is connected to Vnet/IP is 100 Mbps.

- V net router
  A V net router is a device dedicated for connecting a Vnet/IP domain with a V net domain. It performs the frame conversion and filtering between Vnet/IP and V net. The V net router is a station of CENTUM system.
- Wide Area Communication Router (WAC router)
  The wide area communication router is a hardware device dedicated for the communications between Vnet/IP domains distributed in remote areas through a wide area network. The wide area communication router is a device of CENTUM systems.
- HIS
  HIS (Human Interface Station) is an operation and monitoring station of CENTUM. The HIS is used for operation and monitoring of SCS. The CENTUM system builders are required for engineering and maintenance for the HIS and V net routers. The system builders can be installed on the HIS.

TIP

SENG and HIS set up in the virtual machine on the virtualization platform are referred to as a virtual Vnet/IP station. In order to connect the virtual Vnet/IP station to the Vnet/IP network, a software license for the Vnet/IP interface package is required.

SEE ALSO

For more information about the procedures and precautions when adding a Vnet/IP station, refer to:

"■ Procedures and precautions for adding a Vnet/IP station" on page I5-1

● Vnet/IP domain

A Vnet/IP domain consists of two independent subnets of bus 1 and bus 2. Each domain can have a maximum of 64 Vnet/IP stations (SENG, SCS, etc.).

If a safety system is integrated with a CENTUM system, the integrated system can have a maximum of 16 Vnet/IP and V net domains.

SEE ALSO

For more information about the procedures and precautions when adding a Vnet/IP domain, refer to:

"■ Procedures and precautions for adding a Vnet/IP domain" on page I5-2

● Layer 2 switch

Vnet/IP stations and general-purpose Ethernet communication devices in a domain are connected to Vnet/IP buses through the Layer 2 switches (L2SW). At least one L2SW is required for bus 1 and bus 2 respectively.

● Layer 3 switch

A layer 3 switch (L3SW) is used to connect between Vnet/IP domains on each bus.

A1.2 Device Connections in a Vnet/IP Domain

The devices in the Vnet/IP domain are connected in a star topology by using a 1-Gbps layer 2 switch as the hub. The connections among the layer 2 switches should be in a star topology or ring topology. A ring topology can be used with a CENTUM integration configuration only. It cannot be used with a configuration consisting of a ProSafe-RS system only, or a CI Server integration configuration.

Because the redundant Vnet/IP buses are separated as independent subnets of each bus, each bus should have its own layer 2 switch as the hub.

IMPORTANT

Multiple stations are connected to Layer 2 switches. It is strongly recommended to provide an uninterruptible power supply (UPS) for Layer 2 switches so that they will not stop due to power failure.

The following describes the impact when the Layer 2 switch power supply becomes faulty:

- A communication error will occur if Layer 2 switches for the buses stop due to power failure.
- For dual-redundant SCS, if the Layer 2 switches for both buses stop, the control will be switched to the standby CPU in rare cases, causing the dual-redundant SCS to operate in non-redundant mode.
- If a Layer 2 switch is restarted after momentary power failure, it takes several tens of seconds for the communications between stations to recover.

Specification when connecting devices in a Vnet/IP domain

The specification when connecting devices in a Vnet/IP domain is as follows:

- Number of Vnet/IP stations connected (Vnet/IP stations including V net routers) : Max. 64 Stations
- Distance between Vnet/IP stations : Max. 40 km
- Distance between Layer 2 switch and station : Max. 100 m (when UTP cable is used)
- Connection distance between Layer 2 switches: : Max. 5 km (when optical fiber cable is used)
- Levels of Layer 2 switches: : Max. 7 levels

TIP

- For the redundant stations such as the SCS and Vnet router, the respective CPU module and the Layer 2 switch at the control side and the standby side are connected by a UTP cable. The number of connected Vnet/IP stations is counted as one unit.

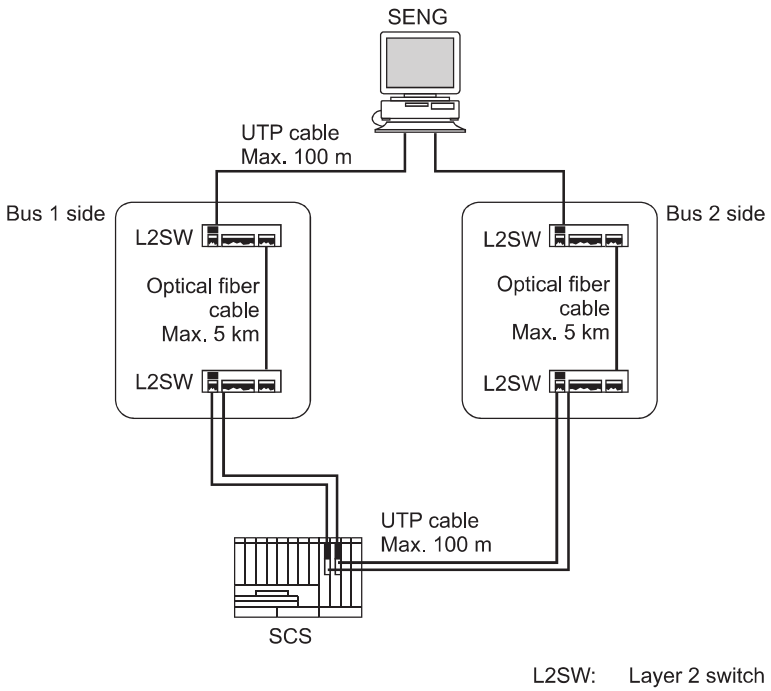

Figure A1.2-1 Example of connections in a Vnet/IP domain

IMPORTANT

When connecting layer 2 switches with a star topology, do not connect in such a way that multiple communication paths exist between any two stations. Otherwise, normal communication is not performed.

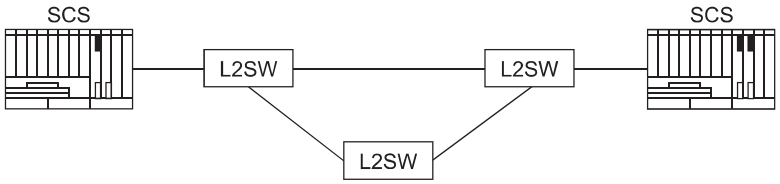

Figure A1.2-2 Example of an incorrect connection

Communication between SENG and SCS

The engineering and maintenance of SCS are performed via Vnet/IP from SENG.

You can perform safety communication between SENG and the SCS of Vnet/IP domains.

The communicable network range is the same as the range in which Inter-SCS safety communication can be performed.

You must connect one or more SENGs to the Vnet/IP network that allows communications with the SCS.

Communication between HIS/FCS and SCS

It is possible to communicate with an SCS in a V net domain or a Vnet/IP domain from an HIS/FCS. The communicable network range is the same as for executing Inter-SCS safety communication.

This communication has no impact on safety functions executed in SCS.

A1.3 Connection between Vnet/IP domains

1-Gbps layer 3 switches are used for connections among the Vnet/IP domains. For a redundantly configured Vnet/IP network, each bus should have a layer 3 switch for the connection of the domains. By using a leased line as the transmission path, the domains can be connected through the wide area networks.

However, connection between Vnet/IP domains is not supported in a ProSafe-RS only system.

IMPORTANT

It is strongly recommended to provide an uninterruptible power supply (UPS) to protect Layer 3 switches so that the Layer 3 switches do not stop upon power failure.

TIP

Wide area communication routers can also be used to connect Vnet/IP domains through a wide area network.

Specifications when connecting Vnet/IP domains

The specification of connection between Vnet/IP domains is as follows:

- Multi-level connection of Vnet/IP domains: Max. 15 levels (16 Layers) of Layer 3 Switches
- Transmission delay between any domains: Less than 80 ms

IMPORTANT

Do not connect in such a way that multiple communication paths exist between any two domains. Otherwise, normal communication is not performed. However, with a CENTUM integration configuration, it is possible to configure the connections among the layer 3 switches connecting adjacent domains in a ring topology.

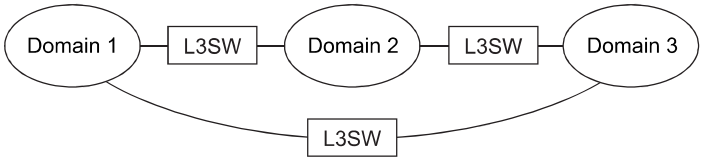

Figure A1.3-1 Example of incorrect connection

Connection between Vnet/IP domains

There are three types of connections between Vnet/IP domains: bi-directional, hierarchical and bridge connections. It is possible to configure a network coexisting these three types of connections. Set the connection types in Domain Properties for each domain using CENTUM engineering builders. The connection type may be selected in accordance with the upper and lower relationships that should be set between connected domains. Decide on the connection type after investigating whether or not message reception, SCS TCP communication or time synchronization is required between connected domains.

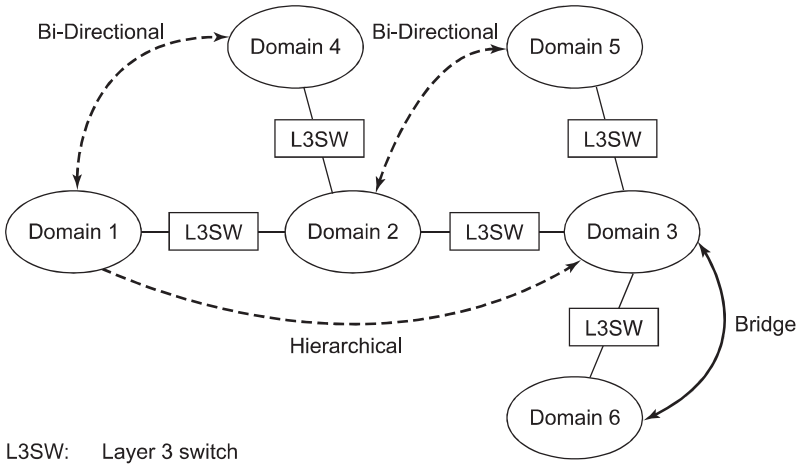

Figure A1.3-2 Domain connection types in Vnet/IP

Setting of TCP/IP communication relay processing

When the system consists of multiple Vnet/IP domains, you must configure the [FCS TCP] setting, which is a domain property setting of a CENTUM system builder. Setting it to ON allows TCP/IP broadcast frames to be relayed in both directions. This function enables the TCP/IP communication between SENG and SCS to be performed across domains.

Bi-directional connection

This connection type does not differentiate the upper and lower relationships between Vnet/IP domains. This type of connection can be established by setting the domain to receive HIS messages, FCS messages and FCS TCP communication frames from other domains. Moreover, when the domain is set to receive FCS messages, it can also receive SCS messages (such as system alarm messages). If the domain is set to receive FCS TCP frames, it can also receive the SCS TCP communication frames. By the default settings on the Domain Properties dialog box, the domain is set to receive all the transmissions.

Hierarchical connection

This connection type differentiates the upper and lower relationships between Vnet/IP domains. This type of connection can be established by setting a lower domain not to receive HIS messages, FCS messages and FCS TCP communication frames from upper domains; but all the stations in the upper domains can receive HIS messages, FCS messages, and FCS TCP communication frames from the lower domain. Moreover, when the domain is set to receive FCS messages, it can also receive SCS messages (such as system alarm messages). If the domain is set to receive FCS TCP frames, it can also receive the SCS TCP communication frames.

Bridge connection

This connection configuration emphasizes the independence among the Vnet/IP domains. In this configuration, the domain properties are configured such that the domains do not receive messages from each other. If time synchronization among the domains is not required, 0 is set in the time group.

IMPORTANT

- If the SCS exists in a Vnet/IP domains that are different from SENG, you need to configure such that the FCS TCP communication is receivable in both domains in order to engineer and maintain the SCS by using SENG.
- When performing inter-SCS safety communication between different Vnet/IP domains, you need to configure such that the FCS TCP communication is receivable in both domains.
- If an SCS that performs inter-SCS safety communication exists in the Vnet domain, you need to configure such that the FCS TCP communication is receivable in both domains. In this case, you need to configure the Vnet router, bus converter (BCV), and communication gateway (CGW) in such a way that the FCS TCP communication is receivable.

TIP

- Even if you select any of these communication configurations, you can access the SCS function block and variables from the CENTUM station across domains by using the tag name.
- You can also set the domain properties so that the domain receives only one type among HIS messages, FCS messages, and FCS TCP communication frames.

System expansion with WAC routers

WAC routers can be used to expand the system by connecting two or more Vnet/IP domains in remote sites using a wide-area network.

You can engineer WAC router by using the System Builders of CENTUM VP. You cannot engineer WAC routers by using the SENG.

Therefore, if you plan to add WAC routers to the system that consists of only SENG and SCS, and connect the system to a wide-area network, the System Builders of CENTUM VP are required.

Moreover, when connecting SCS with wide-area network through WAC routers, install an SENG in each Vnet/IP domain that are connected by WAC routers. Engineering operations such as offline download to SCS must be performed from the SENG that is connected to each Vnet/IP domain. Similarly, install an AD server for each Vnet/IP domain.

The following figure shows an example of system expansion using WAC routers.

The illustrated SENG includes AD Organizer.

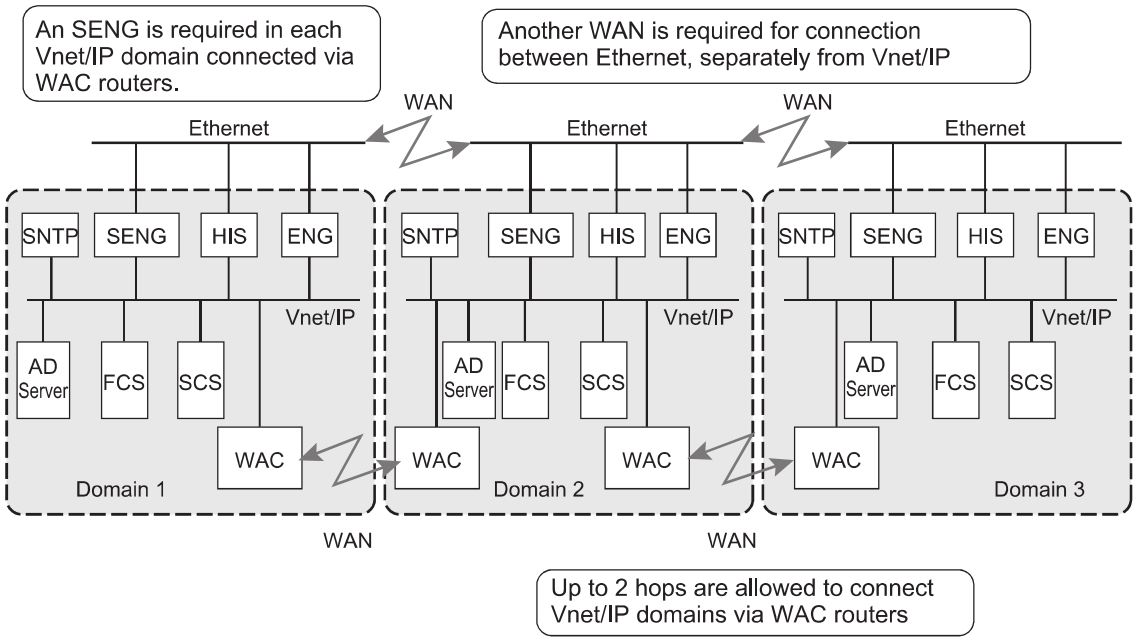

Figure A1.3-3 Example of system expansion with WAC routers

SEE ALSO

For more information about how to configure the WAC router with CENTUM VP R6, refer to:

8, "Wide Area Communication Router" in Communication Devices Reference (IM 33J20B10-01EN)

For more information about how to configure the WAC router with CENTUM VP R5, refer to:

8, "Wide Area Communication Router" in Communication Devices Reference (IM 33K03M10-50E)

Precautions when engineering CENTUM VP systems for using WAC router

A WAC router is engineered on the CENTUM VP side. When connecting the WAC router to ProSafe-RS, be careful of the following points.

Priority control of the Inter-SCS safety communication

A WAC router has the function to give priority to the inter-SCS safety communication, if the communication traffic between Vnet/IP domains exceeds the limit of bandwidth specified in the builder. When performing inter-SCS safety communication through WAC routers, be sure to set WAC routers to enable this function.

Network connection through a wide area network

Connection between Vnet/IP domains can be established through a wide area network for communicating with remote Vnet/IP domains. This type of connection can be established when integrated with CENTUM.

IMPORTANT

If you intend to connect Vnet/IP domains through a wide area network without using wide area communication routers, the following conditions have to be met.

- The transmission delay between any two Vnet/IP domains must be less than 80 ms.
- If inter-SCS safety communications are performed between domains connected through a wide area network, the recommended bandwidth of the wide area network is 100 Mbps or faster.

A2. ProSafe-RS security

ProSafe-RS has the following security functions to prevent access to the system by unauthorized users and devices, and unintended changes caused by operation mistakes made by users.

- Security for the project database
  You can configure the SENG function so that the user is required to enter a password when changing the project data with SCS Manager. (Recommended)
- Security for access to SCS
  You can limit access to SCS from the outside based on the SCS security level. The user is required to enter a password when changing the SCS security level. (Mandatory)
- Security for the SCS Maintenance Support Tool
  On SENG, you can limit writing to SCS with the SCS Maintenance Support Tool by setting a password. (Recommended)
- Access control and operation history management
  Access control and operation history management can be performed on projects that are saved in the AD Server. You can also use the Access control and operation history management package.
- Countermeasures against threats to IT security
  ProSafe-RS security threats include attacks via the network, direct attacks by executing actions on an SENG, and analysis of important data carried out by stealing an SENG. The security features are designed to take measures against these types of security breaches.

This section provides an overview of the ProSafe-RS security function, and the main procedures for setting passwords and implementing security relating to unauthorized access and protection against unintended operations.

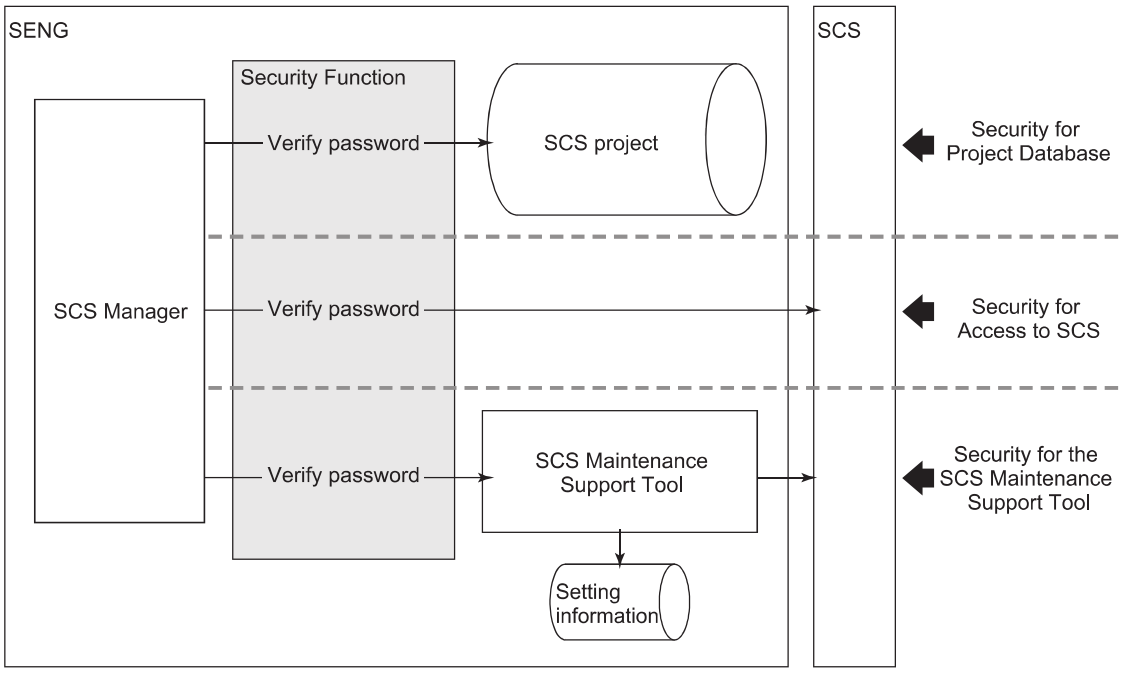

Figure A2-1 Password-based security functions

A2.1 Overview of ProSafe-RS security

The figure below illustrates the security management of SCS and SENG in ProSafe-RS.

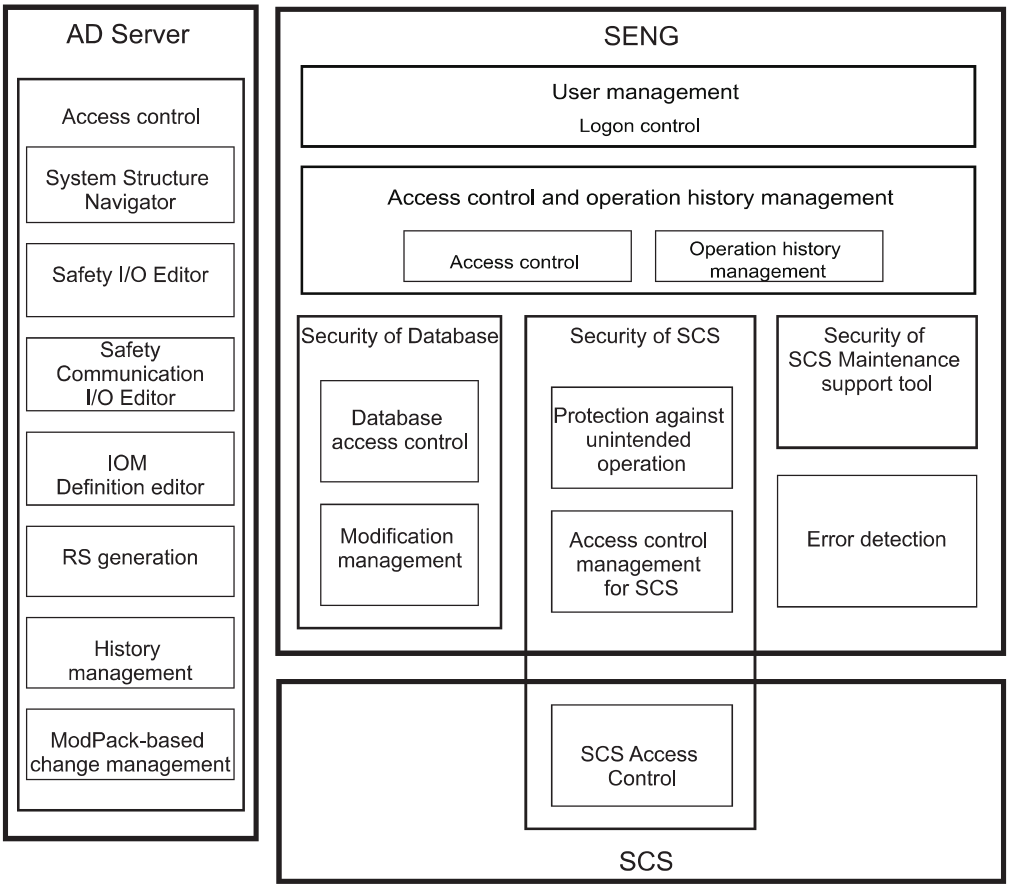

Figure A2.1-1 Overview of security management

IT security

This section describes the requirements for IT security.

For SENG, Windows OS is used as a platform. Therefore, it is necessary to prevent, detect, and recover from computer viruses and attacks from the external through the network. For example, there are countermeasure such as network access control using firewall and system backup.

In the CENTUM Integration Structure, it is necessary to consider comprehensive IT security including ProSafe-RS system and CENTUM system.

You can harden the security of the PC designated as a SENG terminal to enhance the ProSafe-RS IT security (PC hardening). This section describes the details regarding PC hardening and the setting guidelines.

TIP

When integrating ProSafe-RS with CENTUM VP, configure the security settings during installation of ProSafe-RS and installation of CENTUM VP, respectively.

When integrating ProSafe-RS with CS 3000, select Legacy model in IT security tool.

Configure the IT security of the computer that has iDefine installed by referring to iDefine Security Manual (PR03076-MAN-981_01).

If your security model is a legacy model, anyone will be able to start iDefine Test Manager.

If your security model is a standard or strengthened model, any user that belongs to the PSF_ENGINEER or PSF_ENGINEER_LCL group will be able to start iDefine Test Manager.

SEE ALSO

For more information about security configurable on the PC, refer to:

2., “Security Models” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

An example of registering a user to the user account

IT security enhancement for a PC can protect the ProSafe-RS system from the illegal access by any user other than the user of ProSafe-RS user groups. For protecting the ProSafe-RS system from the accidental mistaken accesses by the users of ProSafe-RS groups, the ProSafe-RS Security features should be used. By combining IT security enhancement for a PC and ProSafe-RS Security, you can fortify security of ProSafe-RS.

The typical examples of registering a ProSafe-RS user to the user groups are shown as follows:

(A) ProSafe-RS Engineer (Integrated with CENTUM VP)

ProSafe-RS Engineer user should be assigned to both PSF_ENGINEER group of ProSafe-RS and CTM_ENGINEER group of CENTUM VP.

(B) ProSafe-RS Engineer (Not Integrated with CENTUM VP)

ProSafe-RS Engineer user should be assigned only to the PSF_ENGINEER group.

(C) Maintenance and service persons

The user who requires the role for upgrading SENG software to newer versions, maintaining or changing the hardware components such as I/O modules should be assigned only to the PSF_MAINTENANCE group.

(D) Network and System Administrator (User who is responsible for network maintenance)

This user is considered as the administrative user of Windows environment in SENG. This user needs to be assigned only to the PSF_MAINTENANCE group.

(E) User account for emergency attention (For domain or parallel management in standard model)

When ProSafe-RS system is running in an Windows domain environment, if the domain controller encounters an abnormality, no one can logon to the SENG with the domain account. You need to prepare the user accounts who are assigned to the PSF_MAINTENANCE_LCL group for an emergency attention. If the domain controller encounters an abnormality, user can logon to the SENG with this user account, then maintain and operate ProSafe-RS.

Though the users in the above groups are all granted with the Write permission to all the Project folders, in the cases of (C) and (D), the Write permission is not required. An engineer should define a password by using the security feature of the project database and keep the password as secret to the users whom you do not grant the Write permission so as to protect the project database. Moreover, ProSafe-RS provides security features for accessing the SCS and for Maintenance Support Tool. These security features can be utilized in accordance with the role of the users so as to protect the database and SCS from the accidental operation mistakes.

Database security management

The database has the following security functions.

Access control of the SCS project database

It is possible to set a password for the database used in an SCS project; so that only users who know the password are allowed to make changes to the database. It is also possible to set whether or not to allow users who do not know the password to refer to the database.

Security for AD projects

The following security functions are available for AD projects:

- Management of users who are permitted to access AD projects
- Access control of AD project data

Modification management

This function manages the changes made to SCS projects. It has the following functions:

- Backup
  SCS projects are registered and managed in AD Server.
- Version management
  This function manages the history of changes made to SCS projects.
- Master database management
  SENG always maintains the backup SCS project that keeps the same SCS database with the one running on the SCS.
- Saving modification files
  When you use the Access Control and Operation History Management Package, the changes made to the project database downloaded to the SCS are saved.

Security management of SCS

The SCS has the following security functions.

SEE ALSO For more information about security of SCS, refer to:

B3., “Security of SCS” in ProSafe-RS User’s Guide (IM 32P01B10-01EN)

Prevention of SCS operation mistakes made by users

When a user attempts to perform the following operations on the SCS, the user is prompted to confirm the execution of the operation in order to prevent operational mistakes.

- Offline download
- Online change download
- Master database offline download
- IOM download
- I/O lock
- SCS security level change

Access control to SCS

- Access control based on the security level

Access from outside to SCS is controlled by SCS security levels. Password must be set for changing the SCS security levels (to Level 1 or Level 0). The SCS security level can only be operated using the SCS security level operation function, by users who know the password.

- Access control for each user
  When the Access Control and Operation History Management Package is applied, you can control operations on SCS for each user.

Security management of SCS Maintenance Support Tool

In SCS Maintenance Support Tool, write access to SCS is controlled by setting a password. If the Access Control and Operation History Management Package is used, operations of the SCS Maintenance Support Tool can be controlled for each user.

SEE ALSO For more information about how to set a password for SCS Maintenance Support Tool, refer to:

"■ How to enter SCS Maintenance Support tool password" on page A2-10

SCS Status Overview window, Diagnostic Information window, Setup Tool

The SCS Status Overview window, Diagnostic Information window and Setup Tool are protected by passwords. Each of these functions is launched as read-only unless the correct password is specified.

In the case of the SCS Status Overview window, the password is checked when calling this window from SCS Manager. The Diagnostic Information window and Setup Tool inherit the password of the SCS Status Overview window when they are launched.

When the Access Control and Operation History Management Package is applied, enter the name and password of the engineer.

Message Cache Tool

Message Cache Tool is protected by a password. It is launched as read-only unless the correct password is specified.

SOE Viewer

No password is set up for SOE Viewer because no writing operations to an SCS are performed on SOE Viewer.

Forced I/O Viewer and Forced I/O Viewer Setup Tool

Forced I/O Viewer and Forced I/O Viewer Setup Tool do not perform password authentication at startup.

Access control of AD server

You can control access to individual files and functions of an AD project for each user. You can also set access rights to the files and folders in AD Server according to the role of the user.

System Structure Navigator

You can set the rights to register, unregister, back up, and restore RS projects, edit RS project comments, and delete SCS.

Safety I/O Editor

You can set the rights to create and delete safety I/O lists and assign safety I/O.

- **Safety Communication I/O Editor**

  You can set the rights to create and delete safety communication I/O lists and assign safety communication I/O.

- **IOM Definition Editor**

  You can set the rights to create and delete nodes and I/O modules.

- **RS generation**

  You can set the rights to run RS generation.

- **History management**

  You can set the rights to set and delete labels.

- **ModPack change management**

  You can set the rights to perform operations for each ModPack operation category.

A2.2 Security for project database

This section describes security for project databases.

Setting a password for project databases

You can assign a password to a database to prevent unauthorized users from making changes to the database in SCS projects. Users without entering the password can be given permission for read only operation.

Passwords can be specified for the following.

- For each SCS Project
- For each POU

The reading and writing right for the whole project and the access right for each POU can be controlled using the security function of the SCS project and the security function of each POU.

Set a different password for each SCS Project.

If higher level of security is required, set a password for each important POUs.

You need to set different passwords for each SCS project. These passwords should be different from the one for the SCS security level.

Database files in RS projects should not be changed from tools other than the ProSafe-RS software.

A2.3 Security of SCS Maintenance Support tool

SCS Maintenance Support Tool has a security by setting a password to be entered when starting related windows. A password is set for each SENG.

This section describes how to set passwords for the SCS Maintenance Support Tool.

The password described in this section is not applicable if the Access Control and Operation History Management Package is used. Instead, the user enters the password that is set for each user in the Access Control and Operation History Management Package when starting the SCS Maintenance Support Tool.

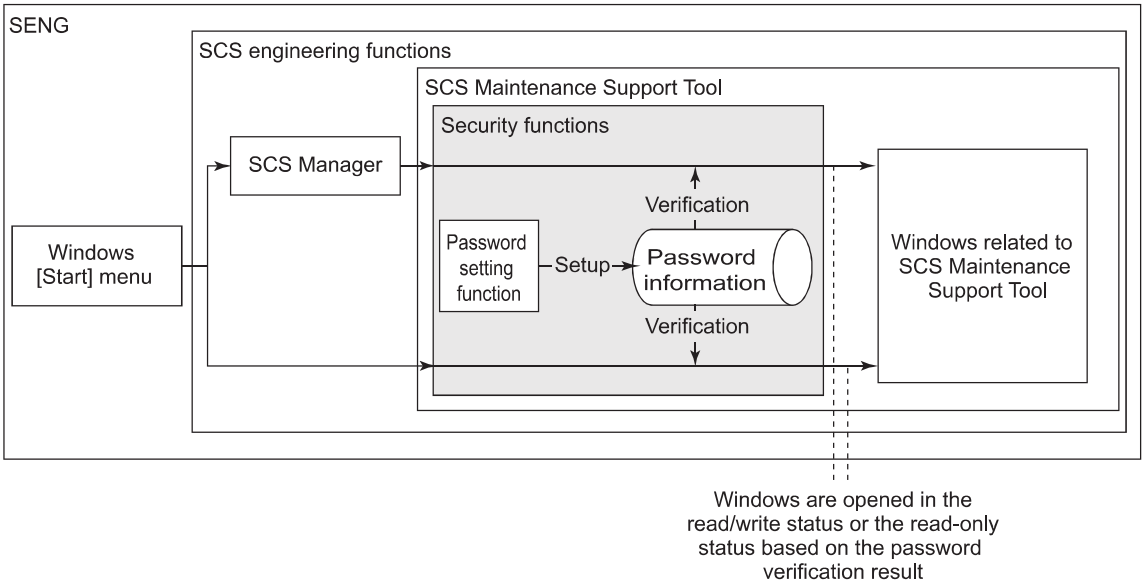

Figure A2.3-1 Security functions of Maintenance Support tool

TIP

No security is set in order to use SOE Viewer as it only displays information.

Setting a password for the SCS Maintenance Support Tool

The SCS Maintenance Support Tool requires a password entry every time you start a window to ensure the security of the SCS access. Password needs to be set for each SENG.

Each tool in the SCS Maintenance Support Tool can be operated for security by entering a password at the start of each tool. When the password entry is cancelled, the tools' operations are disabled for security and the window is in the read-only mode.

The following table shows whether tools can be operated or not when the password is entered and when password entry is cancelled.

Table A2.3-1 Operation of SCS Maintenance Support tool

Tool	Operations provided security	Inputting a password	Without inputting a password
SCS State Management Window	IOM Download	Enabling operation	Read Only
	Output Enable Operation	Enabling operation	Read Only
	Output Module Start Operation	Enabling operation	Read Only
	Setting Time	Enabling operation	Read Only

Continues on the next page

Table A2.3-1 Operation of SCS Maintenance Support tool (Table continued)

Tool	Operations provided security	Inputting a password	Without inputting a password
Diagnostic Information Window	Confirmation and Deletion of Diagnostic information	Enabling operation	Read Only
Setup Tool	Setting and change of display font, color and operating methods for confirming or deleting messages	Enabling operation	Read Only
SOE Viewer	Display of events of SCS and generation of report	Enabling operation	Enabling operation
Message Cache Tool	Setting of message collection, initialization of TRIP information in SCS and storage and deletion of cache data.	Enabling operation	Read Only

How to set and change a password for SCS Maintenance Support tool

The Change Maintenance Support Password dialog box is used to specify or change the password that the user must enter when starting the SCS Maintenance Support Tool.
To use SCS Maintenance Support Tool, make sure to set the password first.

TIP

No password is set automatically after installing SENG. Make sure to set a password at this stage.

1. Open the window related to SCS Maintenance Support Tool from SCS Manager or [Start] menu of Windows.
   When the window requiring a password is opened, the Input Maintenance Support Password dialog box appears.

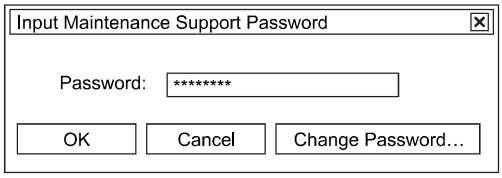

Figure A2.3-2 Input Maintenance Support Password dialog box

2. Click the [Change Password] button.
   The Change Maintenance Support Password dialog box appears.

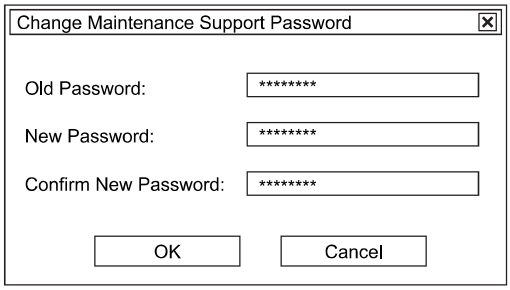

Figure A2.3-3 Change Maintenance Support Password dialog box

3. Enter the current password in the [Old Password:] field. Enter a new password in the [New Password:] field, and once again in the [Confirm New Password:] field.
   The passwords you have entered appear as a series of asterisks (*).

4. Click [OK].
   The password is set.

Specification for passwords

- A password is a maximum 16 of single-byte alphanumeric characters and following symbols including a space character. The password is case-sensitive.
  ! " # $ % & ' ( ) * + , - . / : ; < = > ? @ [¥] ^ _ ` { | } ~
- Set a password for each SENG-installed PC.
- There is no password when SENG is installed for the first time.
- Set a password when starting the SCS Maintenance Support Tool for the first time.

How to enter SCS Maintenance Support tool password

To start SCS Maintenance Support Tool, the correct password must be entered.
Once you enter the correct password, you are allowed to perform writing and customization operations using SCS Maintenance Support Tool.

IMPORTANT

If you fail to enter the correct password, SCS Maintenance Support Tool is started in the read-only status.

1. Open the window related to SCS Maintenance Support Tool from SCS Manager or [Start] menu of Windows.
   When the window requiring a password is opened, the Input Maintenance Support Password dialog box appears.

   If the current window is called from another window of SCS Maintenance Support Tool, the Input Maintenance Support Password dialog box does not appear, because the security is inherited.

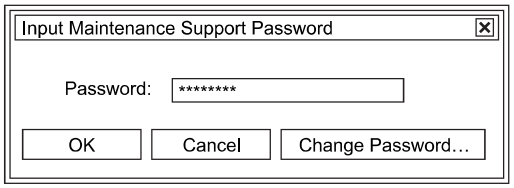

Figure A2.3-4 Input Maintenance Support Password dialog box

2. Enter a password in [Password:] text box.
   All characters you enter are displayed as asterisks (*).
3. Click the [OK] button.
   If you enter the correct password, the window is opened in the read/write status.

   Click the [Cancel] button to start the window related to SCS Maintenance Support Tool in the read-only status.

   Click the [Change Password] button to display the Change Maintenance Support Password dialog box.

A2.4 Access control and history management

When using the Access Control and Operation History Management Package, the functions that can be used by a user are restricted based on the access rights for that user.

SEE ALSO For more information about the Access Control and Operation History Management Package, refer to:

E., “Access Control/Operation History Management functions” in Engineer's Reference Manual (IM 32P04B10-01EN)

User management

The package has a function that enables management of the users who work with SCS Manager and the SCS Maintenance Support Tool. In AD Suite, you can set access rights to the targets of operation for each user role. The user management function is used to register and delete engineers and manage the passwords of engineers. It also keeps records of the operations that were performed by each user.

Access control

The access control function enables you to check engineers who operate the SENG, restrict login or operations on the SENG, and control authorization of engineering operations.

In AD Suite, you can define access rights to files and folders on the AD Server and various functions for all users who perform engineering and maintenance of ProSafe-RS.

Operation history management

This function enables to keep a log of the operations performed by an engineer on the SENG and save the changed project information when a download to an SCS is performed.

In AD Suite, operation history management is available for the following editors and features:

- Safety I/O Editor, Safety Communication I/O Editor, and IOM Definition Editor of AD Organizer
- SCS Manager, builders, and tools including the SCS Maintenance Support Tool
- RS Generation Manager

The change history on all builders and editors is saved on the AD Server and can be viewed in the history window of AD Organizer.

A3. Time synchronization

SCS is capable of synchronizing the time among SCSs, SCS and DI modules to make the event log accurate.

Time synchronization method

SCS for Vnet/IP: Vnet/IP time synchronization is the only option.

Table A3-1 Time synchronization methods

Type	Target SCS	Description
Vnet/IP time synchronization	For Vnet/IP	The system time of SCSs that are connected on Vnet/IP is synchronized with the Vnet/IP network time. If an SNTP server is installed, it is possible to achieve highly accurate time synchronization with the absolute time. The time synchronization status can be checked in the SCS State Management window of the SCS Maintenance Support Tool on SENG, or in the SCS Status Display view on HIS. In Vnet/IP time synchronization, all the stations in one time group that are connected with control bus have the same time data.

Vnet/IP time synchronization method configuration

The following describes the configuration for Vnet/IP time synchronization method.

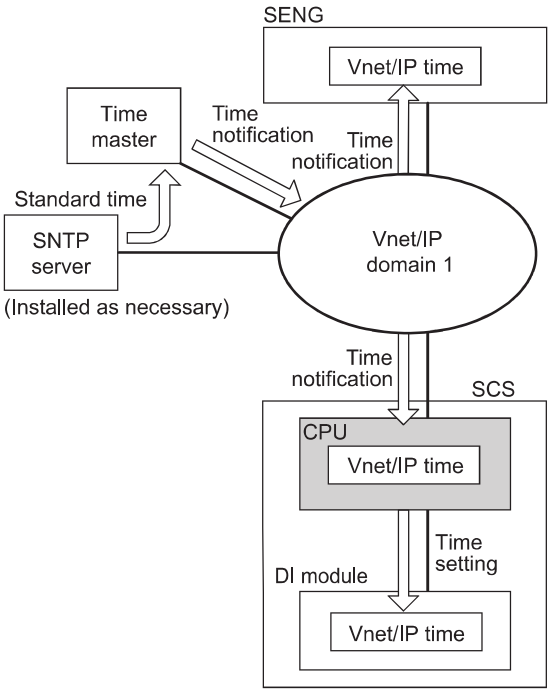

Figure A3-1 Synchronization with Vnet/IP time

- The SCS system time is synchronized with the Vnet/IP network time. When using the synchronization with Vnet/IP time, all stations in the same time group on the Vnet/IP network have the same time information as the clock master. If an SNTP server is installed, the SCS system time is synchronized with the standard time of the SNTP server.
- If the SCS system time is synchronized with the SNTP server time, any time change setting from the SENG or HIS is ignored.
- If the SNTP server is shut down or the SNTP server is not synchronized with the standard time, the SCS system time is automatically synchronized with the clock master of the

same time group (synchronized with internal clock). Accuracy with the standard time drops, but time accuracy between stations is maintained.

Time broadcast to DI modules

The CPU broadcasts the time to DI modules mounted in the station every second.

Selection of Time synchronization method

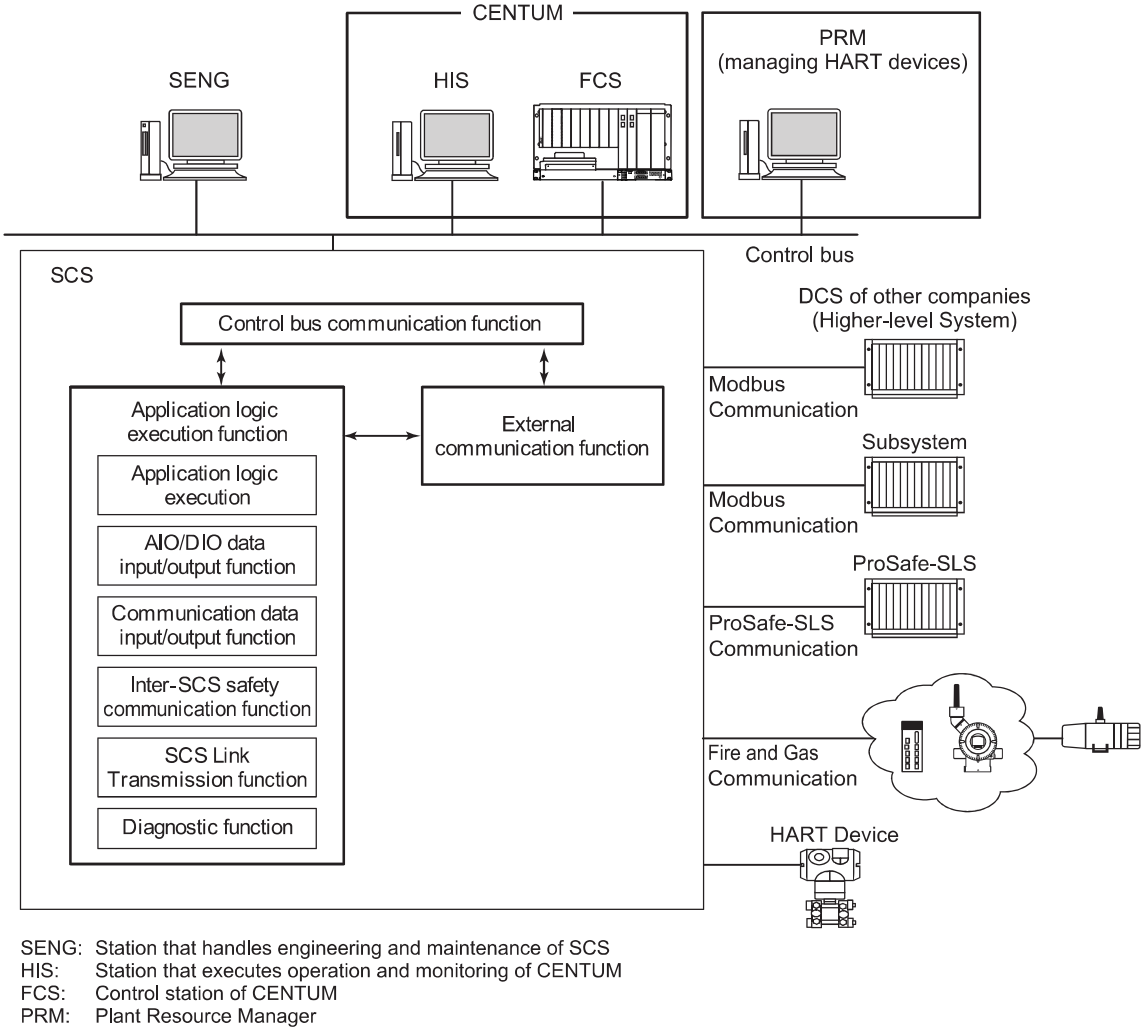
You can set this method by using the SCS Constants Builder.

For an SCS that is connected to Vnet/IP, the Vnet/IP time synchronization method is automatically selected as the time synchronization method.

Precautions when changing the time in Vnet/IP time synchronization

- If the Vnet/IP time synchronizes with the SNTP server, time setting from SENG or HIS is ignored.
- Changing the Vnet/IP time may cause the SOE generation order to be reversed. Be sure to take the timing to set the time and the difference of the time into consideration when setting the V net time.

IMPORTANT



Do not change the Vnet/IP time from more than one SENG or HIS concurrently. It may cause the following errors:

- Self-diagnosis function detects a clock error on the running non-redundant SCS and a system alarm is raised.
- Self-diagnosis function detects a clock error on one of the running redundant SCS and the control right is switched to the standby CPU module.

As a rule, time changes from an HIS/SENG should be made when both buses in the Vnet/IP network are in a normal state. If you change the time from an HIS/SENG during a network failure, there may be stations on which the time does not change immediately, depending on which area of the network has failed and the circumstances of the failure.

A4. Overview of SCS software configuration

SCS is equipped with an application logic execution function for detecting dangerous situations and executing control to prevent or mitigate such situations and an external connection function inclusive of functions for integration with CENTUM which is the production control system of Yokogawa Electric. Note that these functions exchange data with a station on the control bus via a control bus communication function which serves as an interface. In particular, when data is being written into the application logic execution function, the memory inside the SCS is protected with various functions for ensuring safety with such as security levels.

SENG: Station that handles engineering and maintenance of SCS
HIS: Station that executes operation and monitoring of CENTUM
FCS: Control station of CENTUM
PRM: Plant Resource Manager

Figure A4-1 Overview of SCS function configuration

Application logic execution function

This function monitors the safety condition of the plant and makes the process shift to the safety state on detecting any hazards. It mainly performs the following processing.

- Receiving Analog Input (AI)/Digital Input (DI) data from the field
- Execution of user-defined application logic
- Sending Analog Output (AO)/Digital Output (DO) data to the field
- Inter-SCS safety communication

- SCS link transmission
- Communication data I/O (subsystem communication function, safety subsystem communication function)
- Self-diagnosis

Application logic

An SCS executes application logic written in the IEC 61131-3 program language. The application logic is defined by the user using Multi Language Editor and downloaded to the SCS.

An SCS supports the following three languages of IEC 61131-3:

- Function Block Diagram (FBD)
- Ladder Diagram (LD)
- Structured Text (ST)

TIP

The application logic execution function explained here is not simply a name for a function that handles execution of the application logic; rather, it is a generic name for all the functions explained above, including the actual execution of the application logic. In this manual, this term is used in the following explanation as well.

SEE ALSO

For more information about Function Block Diagram (FBD), Ladder Diagram (LD), refer to:

1., “Overview of POU” in POU Reference Manual (IM 32P03B20-01EN)

For more information about Structured Text (ST), refer to:

2., “Structured text” in POU Reference Manual (IM 32P03B20-01EN)

External communication function

This is a function for exchanging information with external systems connected to an SCS and it does not influence the application logic execution function. Main operations are as follows:

- Diagnostic information collection function
- SOER function
- CENTUM Integration Function
- CI Server integration function (SCSP3, SCSP2, SCSP1, and SCSU1)
- Modbus slave communication function
- PRM-supported HART On-demand Communication
- DNP3 communication function (SCSU1 only)

PRM-supported HART on-demand communication

On-demand communication with a HART device is implemented by PRM issuing a HART command, and then receiving a response from the HART device via the SCS. Analog Input/Output modules with HART function serve as communication relays. Specifically, they receive HART communication frames from PRM and send them directly to HART devices, while receiving HART communication frames from HART devices and returning them directly to PRM.

A5. SCS hardware

This section describes the hardware configuration in the SCS, and the important points to determine the configuration.

A5.1 Safety control unit

The following types of safety control units are available:

Table A5.1-1 Types of safety control unit

Model	Name	Safety control unit fan
S2SC70D-S	Duplexed Safety Control Unit (for N-IO/FIO, Rack Mountable Type, Standard Type)	No
S2SC70D-F	Duplexed Safety Control Unit (for N-IO/FIO, Rack Mountable type, Wide Range Temperature Type)	Yes
S2SC70S-S	Safety Control Unit (for N-IO/FIO, Rack Mountable Type, Standard Type)	No
S2SC70S-F	Safety Control Unit (for N-IO/FIO, Rack Mountable Type, Wide Range Temperature Type)	Yes
L1SC70D-S	SIL2, Duplexed Safety Control Unit (for Vnet/IP and FIO, Rack Mountable Type, Standard Type)	No
L1SC70D-F	SIL2, Duplexed Safety Control Unit (for Vnet/IP and FIO, Rack Mountable Type, Wide Range Temperature Type)	Yes
L1SC70S-S	SIL2, Safety Control Unit (for Vnet/IP and FIO, Rack Mountable Type, Standard Type)	No
L1SC70S-F	SIL2, Safety Control Unit (for Vnet/IP and FIO, Rack Mountable Type, Wide Range Temperature Type)	Yes
SSC60D-S	Duplexed Safety Control Unit (for Vnet/IP, Rack Mountable Type, Standard Type)	No
SSC60D-F	Duplexed Safety Control Unit (for Vnet/IP, Rack Mountable Type, Wide Range Temperature Type)	Yes
SSC60S-S	Safety Control Unit (for Vnet/IP, Rack Mountable Type, Standard Type)	No
SSC60S-F	Safety Control Unit (for Vnet/IP, Rack Mountable Type, Wide Range Temperature Type)	Yes
SSC57D-S	Duplexed Safety Control Unit (for Vnet/IP-Upstream, Rack Mountable Type, Standard Type)	No
SSC57D-F	Duplexed Safety Control Unit (for Vnet/IP-Upstream, Rack Mountable Type, Wide Range Temperature Type)	Yes
SSC57S-S	Safety Control Unit (for Vnet/IP-Upstream, Rack Mountable Type, Standard Type)	No
SSC57S-F	Safety Control Unit (for Vnet/IP-Upstream, Rack Mountable Type, Wide Range Temperature Type)	Yes
SSC50D-S	Duplexed Safety Control Unit (for Vnet/IP, Rack Mountable Type, Standard Type)	No
SSC50D-F	Duplexed Safety Control Unit (for Vnet/IP, Rack Mountable Type, Wide Range Temperature Type)	Yes
SSC50S-S	Safety Control Unit (for Vnet/IP, Rack Mountable Type, Standard Type)	No
SSC50S-F	Safety Control Unit (for Vnet/IP, Rack Mountable Type, Wide Range Temperature Type)	Yes
SSC10D-S	Duplexed Safety Control Unit (for Vnet, Rack Mountable Type, Standard Type)	No
SSC10D-F	Duplexed Safety Control Unit (for Vnet, Rack Mountable Type, Wide Range Temperature Type)	Yes
SSC10S-S	Safety Control Unit (for Vnet, Rack Mountable Type, Standard Type)	No
SSC10S-F	Safety Control Unit (for Vnet, Rack Mountable Type, Wide Range Temperature Type)	Yes

Combination of the safety control unit and CPU module

The following shows the applicable combinations of safety control unit models and CPU modules.

Table A5.1-2 Applicable combinations of safety control unit models and CPU modules

Safety control unit model	CPU module
S2SC70S/S2SC70D	SCP461 (Style 2), and S2CP471 (*1) (*2)
L1SC70S/L1SC70D	L1CP471
SSC60S/SSC60D	SCP461 (*3), and S2CP471 (*1) (*2)
SSC57S/SSC57D	SCP451
SSC50S/SSC50D	SCP451
SSC10S/SSC10D	SCP401

*1: Supported in the SCS system program of ProSafe-RS R4.05.00 or later.
*2: When the CPU module is made redundant, SCP461 and S2CP471 cannot be mixed.
*3: Style 1 and style 2 can be used. When the CPU module is made redundant, the style of SCP461 can be mixed.

Definition of SCS station types

Define a station type matching the hardware in the SCS Project Properties window called from SCS Manager. If a CPU module not supported by the defined station type is installed on the control side of SCS, a warning is displayed at offline download. The CPU module will not start even if offline download is executed ignoring the warning. If a correct CPU module is installed on the control side but a CPU module different from the definition is installed on the standby side, the CPU module on the standby side will not start.

A5.2 SCS hardware configuration

This section describes the hardware configurations for SCSs that support SIL 3 and SIL 2.

SCS hardware configuration that supports SIL 3

If the safety control unit is S2SC70D or S2SC70S (SCSP3), these three following methods are available to connect the I/O node to the SCSP3:

- N-IO nodes only connection
- Safety node units only connection
- Combined connection of N-IO nodes and safety node units

If the safety control unit is SSC60D or SSC60S (SCSP2), only the safety node unit can be connected.

The following table shows the main hardware names used in SCS that supports SIL 3.

Table A5.2-1 Main hardware names used in SCS that supports SIL 3

Name	Description	Note
SCU	Safety control unit	SSC60D/SSC60S (*1) and S2SC70D/ S2SC70S
SNU	Safety node unit	SNB10D
PSM	Power supply module	SPW481, SPW482, and SPW484. Always redundant.
CPU	Processor module (CPU module)	SCP461 (SSC60 only), SCP461 S2, and S2CP471
SEC401/ SEC402	ESB bus coupler module	Used when SNU and N-IO nodes are used. Installed in slots 7 and 8 of SCU. Always redundant.
SSB401	ESB bus interface module	Always redundant
SNT401/ SNT411	Optical ESB Bus Repeater Master Module	Always redundant
SNT501/ SNT511	Optical ESB Bus Repeater Slave Module	Always redundant
S2EN402/ S2EN404	N-ESB bus coupler module	Used when N-IO node is used. Installed in SCU. Always redundant.
FIO	FIO I/O module	Analog I/O module that supports SIL 3, digital I/O module that supports SIL 3, and communication module
N-IO node	Node for installing N-IO	Configured with node interface unit and N-IO I/O unit.
PSU	Power supply unit for N-IO	S2PW503 and S2PW504. Always redundant.
S2EN501	N-ESB bus module	Used when N-IO node is used. Installed in N-IO node. Always redundant.
N-IO	N-IO I/O module	Universal type I/O module
ESB bus	Bus to connect SCU and SNU	-
N-ESB bus	Bus to connect SCU and N-IO node	-
Optical ESB bus	Bus to connect SCU, SNU, and N-IO node	-

*1: N-IO node is not connectable.

N-IO node only connection

The following configuration are used when connecting only the N-IO nodes to the safety control unit.

When connecting the safety control unit and N-IO nodes by using the N-ESB bus, the S2EN402/S2EN404 is mounted to the safety control unit, and S2EN501 to the N-IO node. When connecting the safety control unit and N-IO node by using the optical ESB bus, the SEC401/SEC402 is mounted to the safety control unit, and S2EN501 to the N-IO node.

The connection between N-IO nodes must be connected with the N-ESB bus or the optical ESB bus.

The following figure shows an example of configuration with N-IO nodes-only connection.

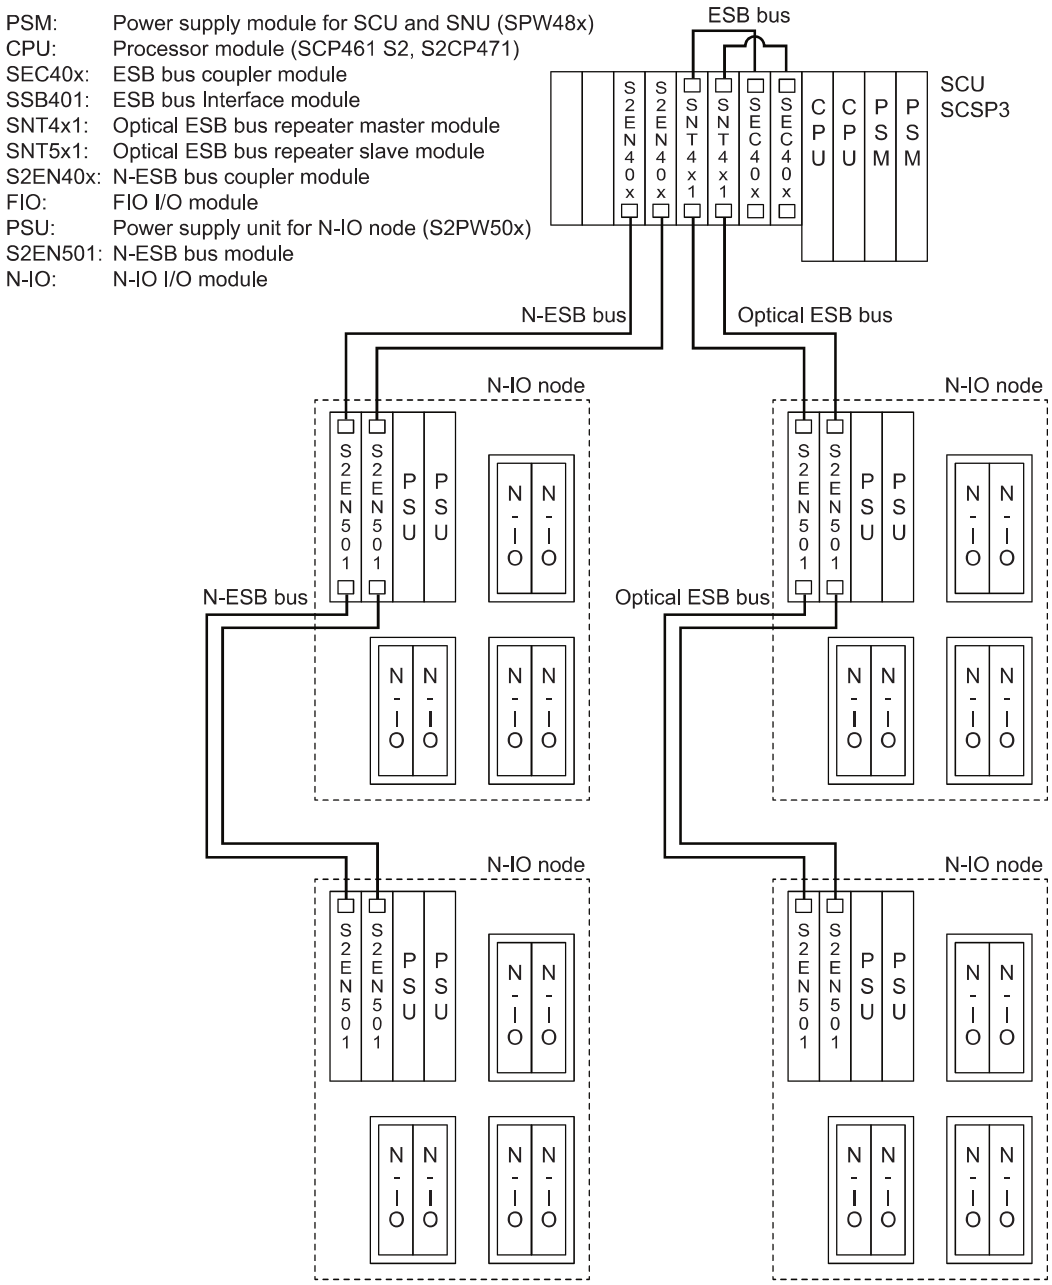


Figure A5.2-1 Configuration example of an N-IO node-only connection

Safety node unit only connection

The following configuration are used when connecting only the safety node units to the safety control unit.

When connecting the safety control unit and safety node unit by using the ESB bus, the SEC401/SEC402 is mounted to the safety control unit, and SSB401 to the safety node unit. When connecting the safety control unit and safety node unit by using the optical ESB bus, the SEC401/SEC402 and SNT401/SNT411 is mounted to the safety control unit, and SNT501/SNT511 and SSB401 to the safety node unit.

The connection between the safety node units must be connected with an ESB bus, or an optical ESB bus through SNT401/SNT411 and SNT501/SNT511.

The following figure shows a configuration example of a safety node units-only connection.

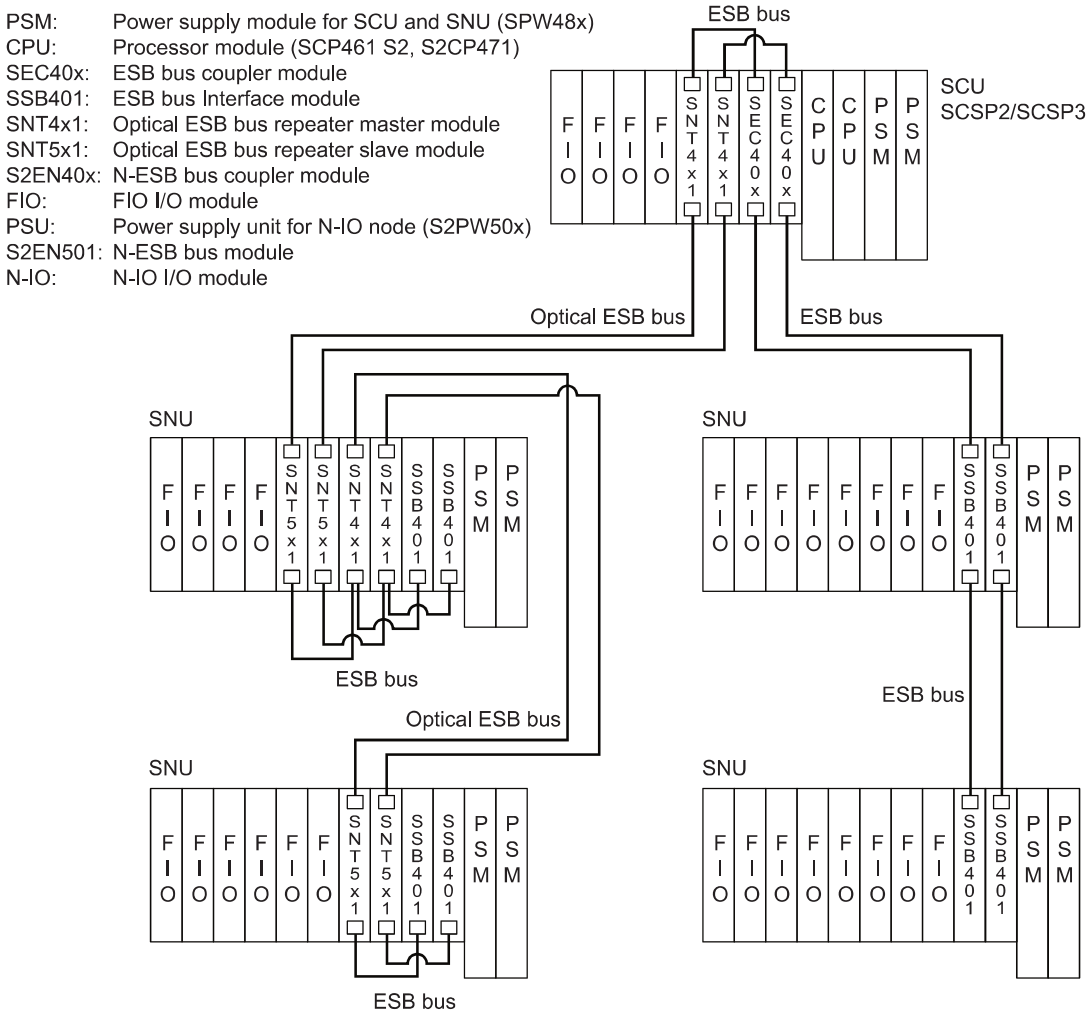

Figure A5.2-2 Configuration example of a safety node units-only connection

Combined connection of N-IO node and safety node unit

N-IO nodes and safety node units can be connected to a single safety control unit. To use both nodes together, you can connect the N-IO node and safety node unit, or separate them.

- Connecting N-IO nodes and safety node units together
  When connecting the safety control unit together with the safety node units and N-IO nodes, connect with the following configuration.

When connecting the safety control unit and N-IO node using the optical ESB bus, the SEC401/SEC402 and SNT401/SNT411 are mounted to the safety control unit, and S2EN501 to the N-IO node.

N-IO node and safety node unit are connected through an optical ESB bus. SNT501/ SNT511 and SSB401 are installed to the safety node unit.

The following figure shows a configuration example of an N-IO node and safety node unit connection.

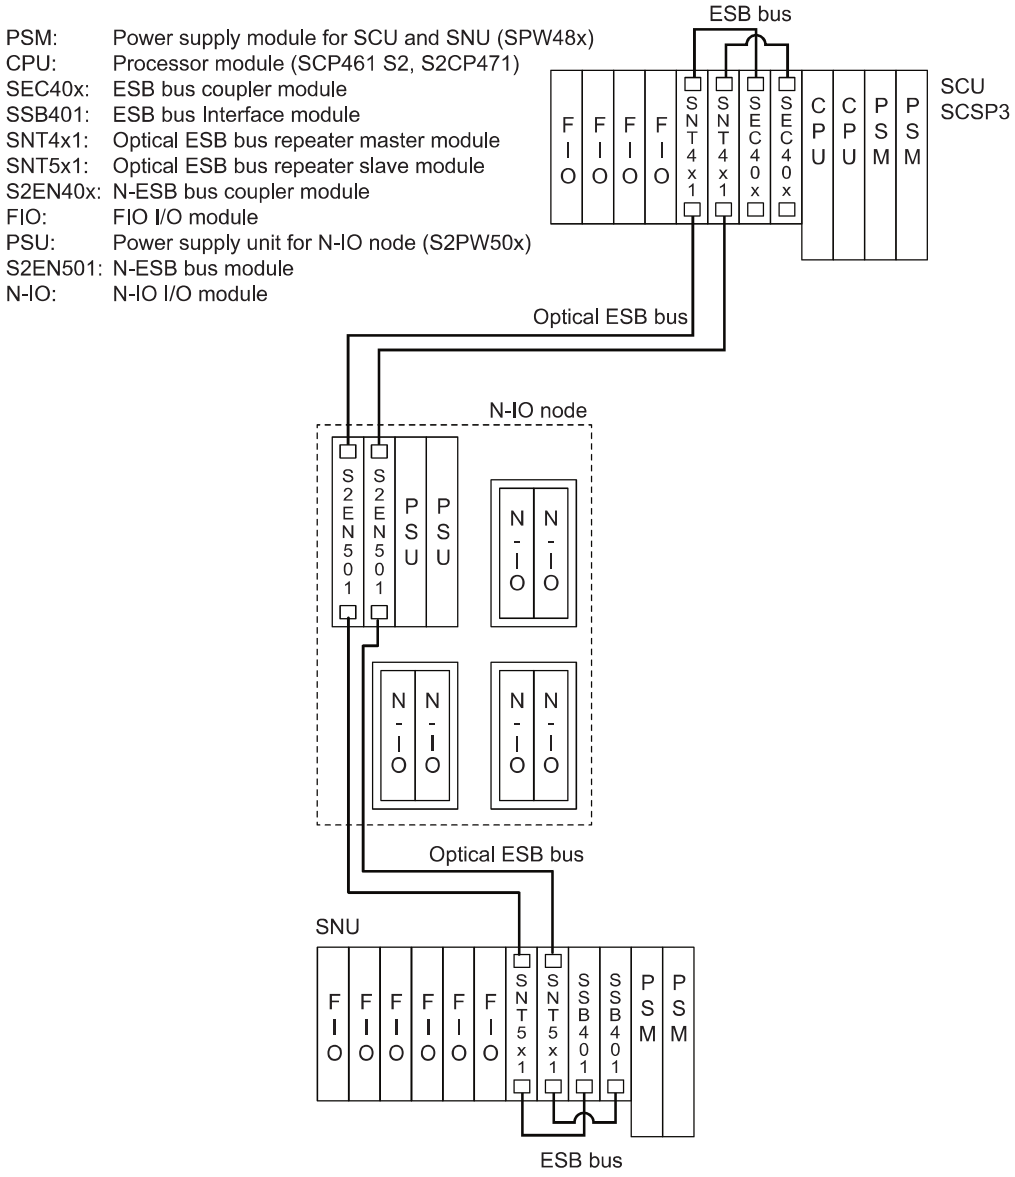

Figure A5.2-3 Configuration example of an N-IO node and safety node unit connection

- Separating N-IO nodes and safety node units, and connecting them together
  When N-IO nodes and safety node units are separated from each other, and they are connected with the safety control unit, the N-IO nodes-only connection and the safety node units-only connection are combined.

  The following figure shows a configuration example when N-IO node and safety node unit are separated and connected together.

PSM: Power supply module for SCU and SNU (SPW48x)
CPU: Processor module (SCP461 S2, S2CP471)
SEC40x: ESB bus coupler module
SSB401: ESB bus Interface module
SNT4x1: Optical ESB bus repeater master module
SNT5x1: Optical ESB bus repeater slave module
S2EN40x: N-ESB bus coupler module
FIO: FIO I/O module
PSU: Power supply unit for N-IO node (S2PW50x)
S2EN501: N-ESB bus module
N-IO: N-IO I/O module

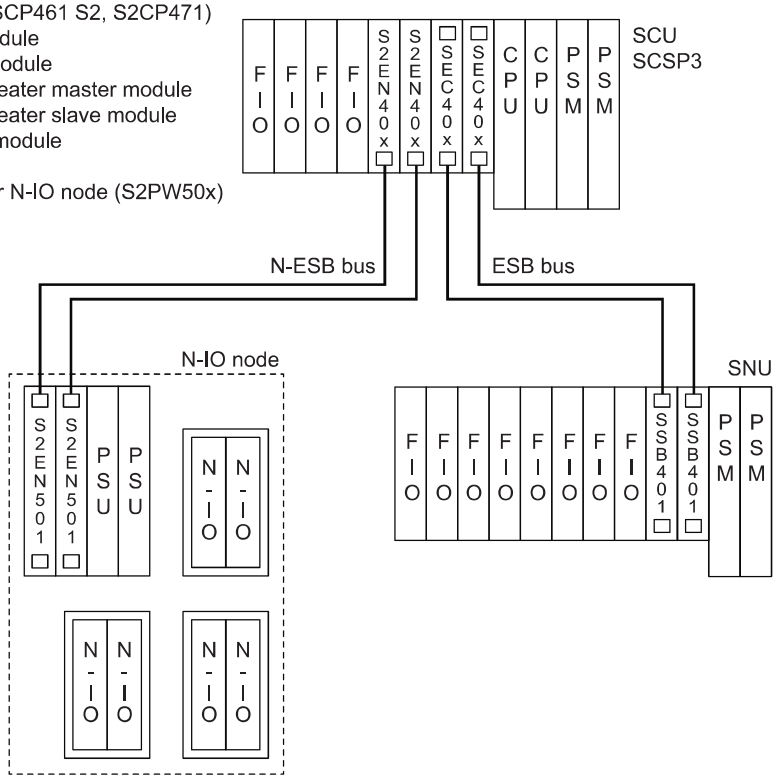

Figure A5.2-4 Configuration example when N-IO node and safety node unit are separated and connected together

SCS hardware configuration that supports SIL 2

If the safety control unit is L1SC70D or L1SC70S (SCSL2), only the safety node unit can be connected.

The following table shows the main hardware names used in SCS that supports SIL 2.

Table A5.2-2 Main hardware names used in SCS that supports SIL 2

Name	Description	Note
SCU	Safety control unit	L1SC70D/L1SC70S
SNU	Safety node unit	L1NB10D
PSM	Power supply module	L1PW481, L1PW482, and L1PW484. Always redundant.
CPU	Processor module (CPU module)	L1CP471
L1EC401/ L1EC402	ESB bus coupler module	Used when SNU is used. Installed in slots 7 and 8 of SCU. Always redundant.
L1SB401	ESB bus interface module	Always redundant
L1NT401/ L1NT411	Optical ESB Bus Repeater Master Module	Always redundant
L1NT501/ L1NT511	Optical ESB Bus Repeater Slave Module	Always redundant
FIO	FIO I/O module	Analog I/O module that supports SIL 2, digital I/O module that supports SIL 2, and communication module
ESB bus	Bus to connect SCU and SNU	-

Continues on the next page

Table A5.2-2 Main hardware names used in SCS that supports SIL 2 (Table continued)

Name	Description	Note
Optical ESB bus	Bus to connect SCU and SNU	-

Safety node unit only connection

The following configuration is used when connecting only the safety node units to the safety control unit.

When connecting the safety control unit and safety node unit by using the ESB bus, the L1EC401/L1EC402 is mounted to the safety control unit, and L1SB401 to the safety node unit. When connecting the safety control unit and safety node unit by using the optical ESB bus, the L1EC401/L1EC402 and L1NT401/L1NT411 are mounted to the safety control unit, and L1NT501/L1NT511 and L1SB401 to the safety node unit.

The connection between the safety node units must be connected with an ESB bus, or an optical ESB bus through L1NT401/L1NT411 and L1NT501/L1NT511.

The following figure shows a configuration example of a safety node units-only connection.

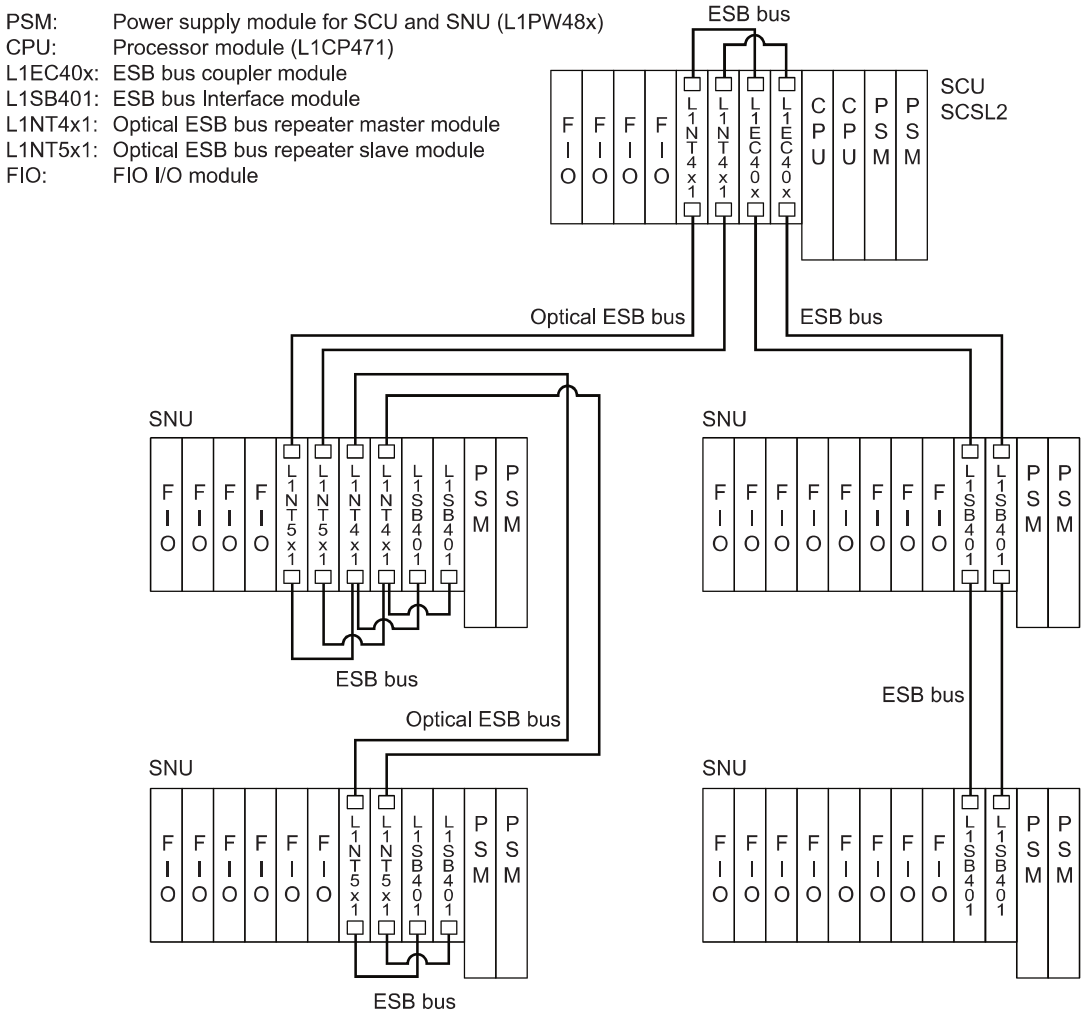

Figure A5.2-5 Configuration example of a safety node units-only connection

A5.3 Restrictions on installation of hardware

There are the following restrictions on the installation of hardware on the SCS.

- To connect a safety node unit in an SCS that supports SIL 3, you need to install SEC401 in slots 7 and 8 of the safety control unit. If you want to connect 10 or more safety node units with SCSP3 or SCSP2, install SEC402 instead. If I/O expansion is not required, you can install I/O modules in slots 7 and 8.
- To connect a safety node unit in an SCS that supports SIL 2, you need to install L1EC401 in slots 7 and 8 of the safety control unit. If you want to connect 10 or more safety node units with SCSL2, install L1EC402 instead. If I/O expansion is not required, you can install I/O modules in slots 7 and 8.
- When installing redundant I/O modules in a safety node unit, you can install the modules in pairs into slots 1 and 2, slots 3 and 4, slots 5 and 6, or slots 7 and 8.
- Up to 8 fire and gas communication modules (S2LP131) can be installed per SCS. S2LP131 can be used for SCSP3.
- For subsystem communication, a maximum of four (up to two pairs in redundant configuration) serial communication modules (ALR111, ALR121) and Ethernet communication modules (ALE111) can be installed per SCS.
- For Modbus slave communication, a total maximum of two modules among serial communication modules (ALR111, ALR121) and Ethernet communication module (ALE111) can be installed.
- In SCSU1, up to two ALE111 modules can be installed for communication as a DNP3 slave.
- A total maximum of eight serial communication modules (ALR111, ALR121) and Ethernet communication modules (ALE111) can be installed per SCS of type SCSU1, and a total maximum of six per SCS of other types of SCS.
- You cannot install the serial communication modules (ALR111, ALR121) and the Ethernet communication module (ALE111) for Modbus slave communication in the safety node unit that is located beyond 5 km by using the optical ESB bus repeater module.

SEE ALSO

ProSafe-RS Lite Installation Guidance (TI 32P51J10-01EN)

I/O module types

The available types of I/O modules include analog I/O module (AIO: Analog Input/Analog Output), digital I/O module (DIO: Digital Input/Digital Output), and a universal type I/O module where the signal category for channels can be changed by software. In addition, communication modules are available for communications with external devices.

TIP If the SCS project was created by SENG of the software release number that does not support the module you want to use, you cannot use that I/O module in the SCS project. To use the I/O module, you must create a new SCS project on the SENG of the software release number that supports the module and perform offline download to the SCS.

Analog I/O modules

Analog input/output modules are used to input/output analog signals that indicate electrical current, voltage, etc. There are analog input/output modules for SCSs that support SIL 3 and those that support SIL 2.

The following table shows the types (models) of analog input/output modules for SCS that supports SIL 3.

Table A5.3-1 Specifications of analog input/output modules for SCS that supports SIL 3

Classification	Type	Description	Number of channels	Redundancy
Analog input	SAI143	4 to 20 mA, module isolation	16	Allowed
	SAV144	1 to 10 V, module isolation	16	Allowed
	SAT145	Thermocouple/mV, isolated channels	16	Allowed
	SAR145	Resistance temperature detector, isolated channels	16	Allowed
Analog output	SAI533	4 to 20 mA, module isolation	8	Allowed

The following table shows the types (models) of analog input/output modules for SCS that supports SIL 2.

Table A5.3-2 Specifications of analog input/output modules for SCS that supports SIL 2

Classification	Type	Description	Number of channels	Redundancy
Analog input	L1AI143	4 to 20 mA, module isolation	16	Allowed
	L1AV144	1 to 10 V, module isolation	16	Allowed
	L1AT145	Thermocouple/mV, isolated channels	16	Allowed
	L1AR145	Resistance temperature detector, isolated channels	16	Allowed
Analog output	L1AI533	4 to 20 mA, module isolation	8	Allowed

- SAI143/L1AI143
  An analog input module for electrical current. Modules whose suffix code is SAI143-H/L1AI143-H support HART communication and are indicated as SAI143H/L1AI143H in the SCS State Management Window on the SENG or the SCS Status Display view on the HIS. SAI143-H can be used with software release number of R1.02.00 or later.
- SAV144/L1AV144
  An analog input module for electrical voltage.
- SAT145/L1AT145
  An analog input module for thermocouple (TC)/mV. SAT145 can be used with software release number of R3.01.00 or later.
- SAR145/L1AR145
  An analog input module for the resistance temperature detector (RTD). SAR145 can be used with software release number of R3.01.00 or later.
- SAI533/L1AI533

An analog output module for electrical current. SAI533 can be used with software release number of R1.02.00 or later. It is indicated as SAI533H/L1AI533H in the SCS State Management Window on the SENG or the SCS Status Display view on the HIS. This module supports HART communication.

Digital I/O modules

Digital input/output modules are used to input/output processes that use discrete on/off signals. There are digital input/output modules for SCSs that support SIL 3 and those that support SIL 2.

The following table shows the types (models) of digital input/output modules for SCS that supports SIL 3.

Table A5.3-3 Specifications of digital input/output modules for SCS that supports SIL 3

Classification	Type	Description	Number of channels	Redundancy
Digital input	SDV144	24 V DC, module isolation	16	Possible
Digital output	SDV521	24 V DC, module isolation	4	Possible
	SDV531	24 V DC, module isolation	8	Possible
	SDV53A	48 V DC, module isolation	8	Possible
	SDV541	24 V DC, module isolation	16	Possible
	SDV526	100 to 120 V AC, module isolation	4	Possible

The following table shows the types (models) of digital input/output modules for SCS that supports SIL 2.

Table A5.3-4 Specifications of digital input/output modules for SCS that supports SIL 2

Classification	Type	Description	Number of channels	Redundancy
Digital input	L1DV144	24 V DC, module isolation	16	Possible
Digital output	L1DV521	24 V DC, module isolation	4	Possible
	L1DV531	24 V DC, module isolation	8	Possible
	L1DV53A	48 V DC, module isolation	8	Possible
	L1DV541	24 V DC, module isolation	16	Possible
	L1DV526	100 to 120 V AC, module isolation	4	Possible

- SDV144/L1DV144
  A digital input module. This module provides SOER (Sequence of Events Recorder) function.
- SDV521/L1DV521
  This module is for 4-channel digital output.
- SDV531/L1DV531
  This module is for 8-channel digital output. There are two types of SDV531: SDV531-S, which is the standard type, and SDV531-L, which supports long distances. L1DV531 has only L1DV531-L which supports long distances.
- SDV53A/L1DV53A
  This module is for 8-channel 48 V DC digital output.
- SDV541/L1DV541
  This module is for 16-channel digital output.

- SDV526/L1DV526
  This module is for 4-channel 100 to 120 V AC digital output.

TIP

- Short circuits between channels cannot be detected in SDV526/L1DV526. In addition, the following faults cannot be detected while the output is OFF:
  - Short circuits in output wiring
  - Output overload (faults in field devices that cause short circuits or overcurrent when the module's output is set to ON)
- Satisfy either of the following conditions when creating an application logic that repeatedly outputs ON and OFF with SDV526/L1DV526:
  - The signal value is maintained for at least 1 s with each ON signal.
  - The signal value is maintained for at least 1 s with each OFF signal.

  These are conditions required in order to detect wiring errors and internal failures and correctly notify diagnosis information. There are no restrictions for cases involving the output of single-shot pulses.

Universal type I/O module

The signal category of the universal type I/O module can be switched by software. The universal type I/O module can only be used with SCSP3.

The following table shows the types (models) of the universal type I/O module.

Table A5.3-5 Universal type I/O module specifications

Model	Name	Description	Number of channels	Redundancy
S2MMM843	Analog digital I/O module	16 channel, module Isolation Analog I/O (AI/AO): 4 to 20 mA, HART compatible Digital I/O (DI/DO): 24V DC You can switch the signal category to AI, AO, DI, or DO for each channel. To use analog output (AO), it is 8 channels for every I/O module. For digital output (DO), a high current output function that combines two or three consecutive channels is supported. 1.3 A, 2.0 A	16	Allowed
S2MDV843	Digital I/O Module	16 channel, module Isolation Digital I/O (DI/DO): 24V DC You can switch the signal category to DI or DO for each channel. For digital output (DO), a high current output function that combines two or three consecutive channels is supported. 1.3 A, 2.0 A	16	Allowed

TIP

Satisfy either of the following conditions when creating an application logic which repeatedly outputs ON and OFF with the DO of S2MMM843 or S2MDV843:

- The signal value is maintained for at least 0.5 s with each ON signal.
- The signal value is maintained for at least 2 s with each OFF signal.

However, there are no restrictions for cases involving the output of single-shot pulses.

Failure detection may not be available in cases when ON/OFF signals are continuously modified in cycles which never satisfy either one of the conditions.

Example of a case where failure detection will be unavailable: An application logic which repeatedly outputs an ON signal for 0.3 s and an OFF signal for 0.3 s

Examples of cases where failure detection will be available:

- An application logic which repeatedly outputs an ON signal for 0.5 s and an OFF signal for 0.5 s
- An application logic which repeatedly outputs an ON signal for 0.3 s and an OFF signal for 2 s

The DO of S2MMM843 and S2MDV843 performs a diagnosis of short circuits and disconnected wiring upon the output of a signal. However, a certain amount of time is required from when the output has changed to when the diagnosis result is refreshed.

- When the signal has changed from OFF to ON, a maximum of 0.5 s is required from when the output has changed to when the diagnosis result is refreshed.
- When the signal has changed from ON to OFF, a maximum of 2 s is required from when the output has changed to when the diagnosis result is refreshed.

When a change of output is repeated in a shorter interval than the time required to refresh the diagnosis results, a state where the diagnosis results are not updated will continue. Refrain from creating such application.

Serial communication modules

Serial communication modules are used to implement Modbus slave communication, where an SCS acting as a Modbus slave communicates with an external device acting as the Modbus master, and are also used to implement subsystem communication, where an SCS communicates with a subsystem. Serial communication modules can be used with SCSs that support both SIL 3 and SIL 2.

- ALR111: Serial communication module (RS-232C)
  It is an interference-free communication module with an RS-232C interface.
- ALR121: Serial communication module (RS-422/RS-485)
  It is an interference-free communication module with an RS-422 or RS-485 interface.

Take note on the following cautions when using the serial communication modules:

- You need to prepare separate modules for Modbus slave communication and subsystem communication.
- When used for Modbus slave communication, serial communication modules cannot have a redundant configuration. If redundancy is required, use two serial communication modules and provide redundancy using a user application.
- Serial communication modules can be configured as redundant modules if used for subsystem communication.
- In a safety control station, the serial communication module for Modbus slave communication cannot be implemented in the safety node unit that is installed at a distance longer than 5 km by using an optical ESB bus repeater module.
- A redundant configuration cannot be used if ALR121 is used for the ProSafe-SLS communication function.

Ethernet communication module

The Ethernet communication module is used to establish the Modbus slave communication that connects the external device of the Modbus master with the SCS of the Modbus slave, and the subsystem communication that connects the SCS with the subsystem. It is also used for the DNP3 communication in SCSU1. Ethernet communication modules can be used with both SCSs that support each of SIL 3 and SIL 2.

- ALE111: Ethernet communication module
  It is an interference-free communication module with a 10BASE-T interface.

Take note on the following cautions when using the Ethernet communication module:

- When used for Modbus slave communication, the Ethernet communication modules cannot have redundant configuration. If redundancy is required, you need to use two Ethernet communication modules and provide redundancy through user application.
- The modules can be configured as redundant modules if used for subsystem communication.
- For DNP3 slave function, the redundant configuration cannot be set by using two modules.
- When the CPU node of SCS is SSC10D or SSC10S, do not define ALE111.
- The Ethernet communication module used for Modbus slave communication or DNP3 communication cannot be installed in the FIO node that is located beyond 5 km by using the optical ESB bus repeater module.

Fire and gas communication module

The fire and gas communication module can be used for fire and gas communication to connect to gas detectors. The fire and gas communication module can only be used with SCSP3.

- S2LP131: Fire and gas communication module
  A communication module with a 100BASE-TX interface.

Take note on the following cautions when using a fire and gas communication module:

- The modules cannot have a redundant configuration.

Installation using devices related to optical ESB bus repeater

In SCS, I/O nodes and N-IO nodes are connected via the ESB bus that is the I/O bus of the SCS. When nodes are to be located at remote places, the ESB bus can be extended by using optical ESB bus repeater modules and fiber-optic cables via the ESB bus coupler module.

Optical ESB bus repeater modules are used by installing them on CPU node, I/O nodes, and nodes for optical ESB bus repeater modules.

Related hardware

There are related hardware devices for SCSs that support SIL 3 and those that support SIL 2.

The following table shows the optical ESB bus repeater modules for SCS that supports SIL 3.

Table A5.3-6 Optical ESB bus repeater modules for SCS that supports SIL 3

Model	Name	Description
SNT401/ SNT411	Optical ESB Bus Repeater Master Module	Master module for extending ESB bus with fiber-optic cable(s). SNT411 supports extending of the long distance.
SNT501/ SNT511	Optical ESB Bus Repeater Slave Module	Slave module for extending ESB bus with fiber-optic cable(s). SNT511 supports extending of the long distance.

The following table shows the optical ESB bus repeater modules for SCS that supports SIL 2.

Table A5.3-7 Optical ESB bus repeater modules for SCS that supports SIL 2

Model	Name	Description
L1NT401/ L1NT411	Optical ESB Bus Repeater Master Module	Master module for extending ESB bus with fiber-optic cable(s). L1NT411 supports extending of the long distance.
L1NT501/ L1NT511	Optical ESB Bus Repeater Slave Module	Slave module for extending ESB bus with fiber-optic cable(s). L1NT511 supports extending of the long distance.

The following table shows the related devices when using optical ESB bus repeater modules for SCS that supports SIL 3.

Table A5.3-8 Related devices when using optical ESB bus repeater modules for SCS that supports SIL 3

Model	Name	Description
SEC402/ SEC401	ESB bus coupler module	Module installed in the CPU node and for communication with the I/O node and N-IO node. SEC402 has two ports for ESB bus. Upper and Lower. SEC401 has one port for ESB bus.
SSB401	ESB bus interface module	Module installed in the I/O node and for communication with the ESB bus coupler module
S2EN501	N-ESB bus module	Module that is installed in the N-IO node. Using this module, N-IO nodes can be connected with fiber-optic cable(s)
SNT10D	Unit for Optical ESB Bus Repeater Module	Node dedicated for mounting optical ESB bus repeater modules. The power supply modules are duplicated.

The following table shows the related devices when using optical ESB bus repeater modules for SCS that supports SIL 2.

Table A5.3-9 Related devices when using optical ESB bus repeater modules for SCS that supports SIL 2

Model	Name	Description
L1EC402/ L1EC401	ESB bus coupler module	Module installed in the CPU node and for communication with the I/O node. L1EC402 has two ports for ESB bus. Upper and Lower. L1EC401 has one port for ESB bus.
L1SB401	ESB bus interface module	Module installed in the I/O node and for communication with the ESB bus coupler module
L1NT10D	Unit for Optical ESB Bus Repeater Module	Node dedicated for mounting optical ESB bus repeater modules. The power supply modules are duplicated.

- When connecting FIO nodes in an SCS that supports SIL 3, use SNT401 and SNT501 or SNT411 and SNT511 in pairs. SNT411 and SNT511 cannot be mounted on SCSV1.
- When connecting FIO nodes in an SCS that supports SIL 2, use L1NT401 and L1NT501 or L1NT411 and L1NT511 in pairs.
- The ESB bus coupler module, ESB bus interface module, N-ESB bus module, and optical ESB bus repeater module must be used in redundant configuration. The fiber-optic cable is also used in redundant configuration. It is recommended that the two cables in a pair be the same length.
- The following table shows the optical attenuation required for the optical ESB bus repeater module when the optical transmission distance is 5 to 50 km. If the conditions are not met, use an attenuator to ensure that the conditions are met.

Table A5.3-10 Optical attenuation required for the optical ESB bus repeater module

Module to be used	Required attenuation
SNT411 and SNT511 of Style S2 and above S2EN501 L1NT411, L1NT511	3 dB or more
SNT411 and SNT511 of Style S1	1 dB or more

SEE ALSO

For more information about the specifications and installation restrictions of hardware used in relation to the optical ESB bus repeater, refer to:

Safety Instrumented System ProSafe-RS System Specifications (for Vnet/IP) (GS 32P01B10-01EN)

For more information about specifications, implementation restrictions, etc., of related hardware for optical ESB bus repeaters that support SIL 2, refer to:

Safety Instrumented System ProSafe-RS Lite System Specifications (GS 32P51B10-01EN)

Node types and installable slots

The following table shows the slot numbers where the optical ESB bus repeater module can be installed for each installation node type.

Table A5.3-11 Optical ESB bus repeater module and installable slots

Node type	Slot number
CPU node	1 to 6
I/O node	1 to 8 (*1)
Unit for Optical ESB Bus Repeater Module	1 to 10

*1: An I/O node is a node for installing an I/O module. Therefore, it is not possible to install only the optical ESB bus repeater modules in the I/O node without installing the I/O module.

The optical ESB bus repeater module has Mounting unit setting switch 1. Change the settings according to the node type that will be installed. The following table shows the required settings for each installation node type.

Table A5.3-12 Switch setting of the optical ESB bus repeater module according to the node type to be installed

Node type	Mounting unit setting switch 1 (*1)	The impact when it was not set definitely
CPU node and I/O node	Is set to 1.	If it is set to 0, an error in one of the power-supply modules of the nodes will be notified as a failure of the one-side optical ESB bus repeater module.
Unit for Optical ESB Bus Repeater Module	Is set to 0.	If it is set to 1, one-sided error of the power-supply modules of the Unit for optical ESB bus repeater module will not be notified.

*1: The default setting of Mounting unit setting switch 1 is 0. This setting status can be checked by the display of the status display lamp (NODE 1) on the front of the module. Only the number 1 is the LED lamp. When the Mounting unit setting switch 1 is set to 1, the number 1 is turned on in green.

Maximum number of nodes that can be connected according to ESB bus coupler module type

The maximum number of I/O nodes that can be connected excluding CPU nodes is shown for each ESB bus coupler module type. For the connection specifications of the SCSP3 node interface unit, refer to the General Specifications.

For SCS that supports SIL 3

- When using SEC402
  SCSP3/SCSP2: 13 I/O nodes

- When using SEC401
  9 I/O nodes

For SCS that supports SIL 2

- When using L1EC402
  13 I/O nodes
- When using L1EC401
  9 I/O nodes

ESB bus extendable distance for each optical ESB bus repeater device

The transmission distance of ESB bus can be extended by using the optical ESB bus repeater device. The following table shows the extendable transmission distance for each device. Refer to the General Specifications for the extendable distance for each N-IO node connection method not mentioned here.

Table A5.3-13 ESB bus extendable distance for each optical ESB bus repeater device

Devices to be used		Extendable distance
ESB bus coupler module (electric signal)	SEC402, L1EC402	Upper: 10 m, Lower: 10 m
	SEC401, L1EC401	10 m
Optical ESB bus repeater module	Combination of SNT401 and SNT501, or combination of L1NT401 and L1NT501	5 km
	Combination of SNT411 and SNT511, or combination of L1NT411 and L1NT511	5 to 50 km
N-ESB bus module (for N-IO)	Between SNT411 and S2EN501 Between S2EN501 and SNT511	5 to 50 km

SEE ALSO For more information about connection specifications of N-IO node, refer to:

Model S2NN30D Node Interface Unit (for N-IO) (GS 32P06F20-01EN)

Maximum extension distance of fiber-optic cable

The total extension distance of the fiber-optic cable between the CPU node and the final node is called "Maximum extension distance of fiber-optic cable." The maximum extension distance of fiber-optic cable is 50 km (however, it is 5 km for SCSV1).

I/O nodes and N-IO nodes can be connected in chain or in star by using the optical ESB bus repeater device. Connection methods can be mixed.

One set of optical ESB bus repeater master module and optical ESB bus repeater slave module is counted as 1 layer, and up to 2 layers can be connected. If N-IO nodes are connected with fiber-optic cable(s), they can be connected up to 16 layers. However, if the system has N-ESB buses or I/O nodes, up to 2 layers can be connected.

The selection of optical ESB bus repeater modules or the distances between nodes can be combined freely as long as it is within the maximum optical fiber cable extension distance. The examples are as follows. Modules in brackets indicate devices for SCS that supports SIL 2.

- It shall be 10 km by connecting the distance between SNT401 and SNT501 (L1NT401 and L1NT501) up to 2 layers with 5 km each.
- It shall be 50 km in total by using SNT401/SNT501 (L1NT401/L1NT501) for the first layer (5 km), and SNT411/SNT511 (L1NT411/L1NT511) for the second layer (45 km).

Wiring examples using optical ESB bus repeater devices

The following figures show wiring examples using optical ESB bus repeater devices, divided by type of node to be connected.

- FIO node only connection example

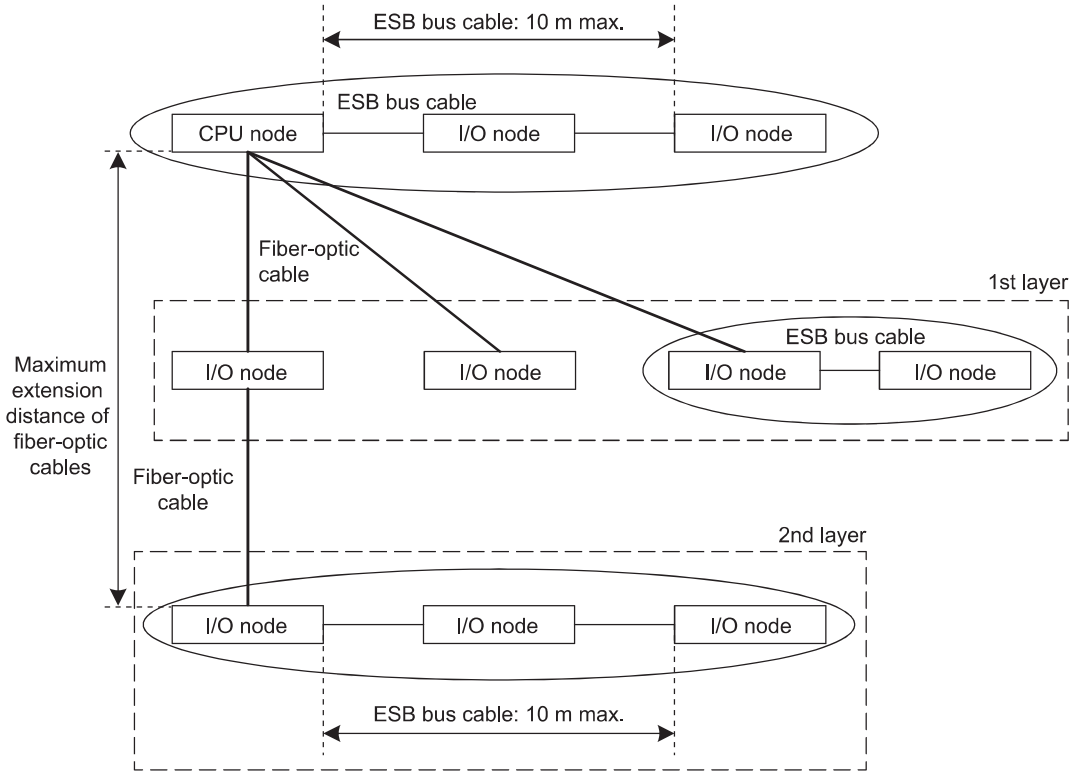

Figure A5.3-1 Overview of the optical ESB bus repeater connection function with FIO

- N-IO node only connection example

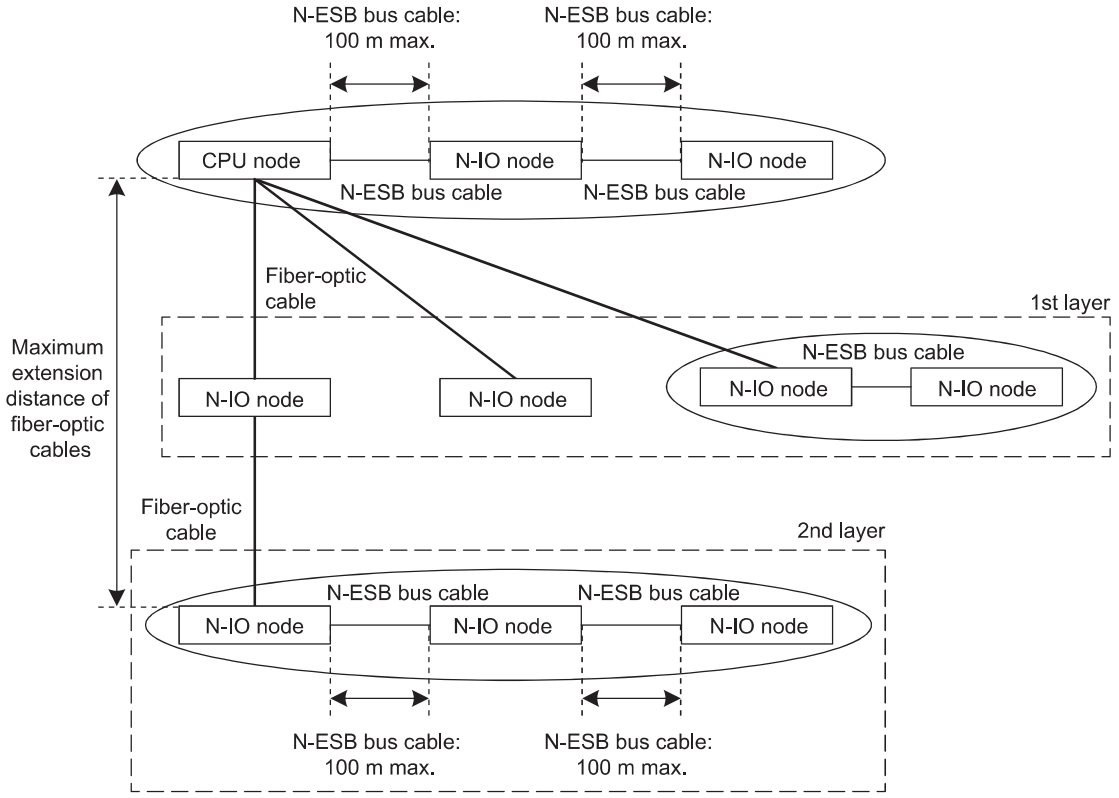

Figure A5.3-2 Overview of the optical ESB bus repeater connection function with N-IO

- FIO node and N-IO node mixture connection example

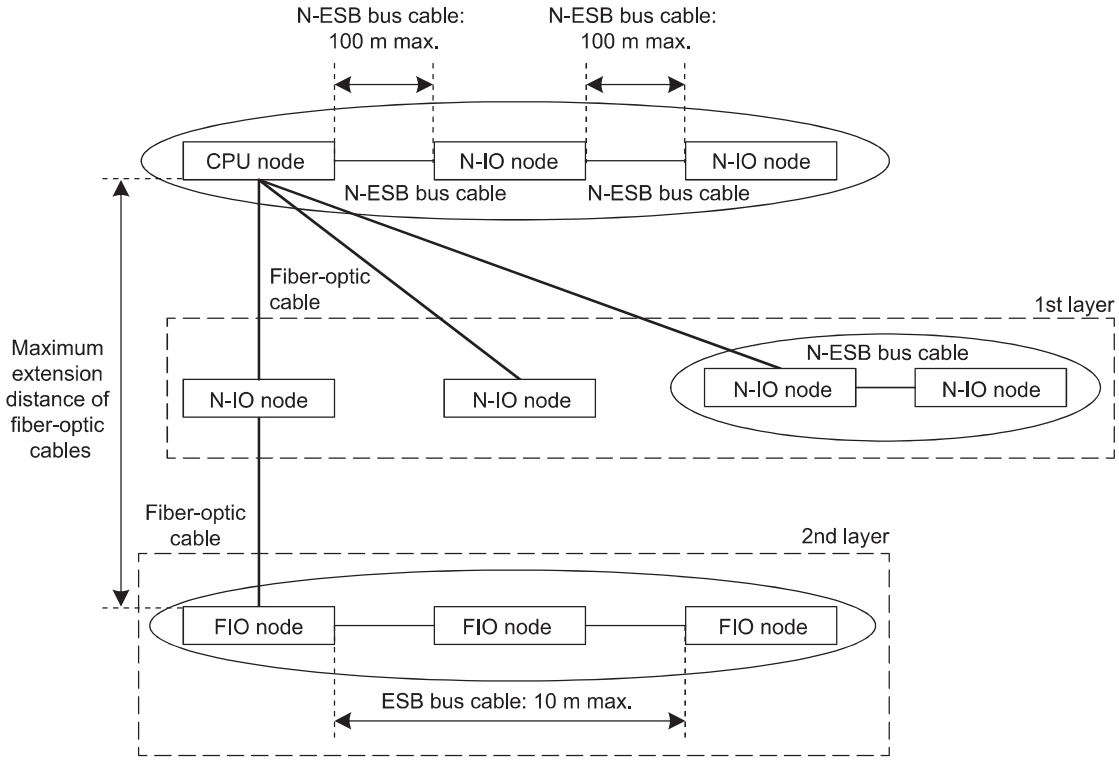

Figure A5.3-3 Overview of the optical ESB bus repeater connection function with N-IO+FIO

Related builder definition items

When connecting nodes via the optical ESB bus repeater module, definitions in the builders are required. If they are not defined properly, the following problems may occur.

- The data of the I/O module installed in the nodes is not updated correctly.
- SOE data is not updated correctly.
- The time required for communication module startup (ALR111, ALR121, or ALE111) becomes longer.
- In the station that supports Modbus slave communication or DNP3 communication, this communication cannot be performed correctly.

The following describes the definitions required for each SCS type and the specific impact of the SCS type if it is not defined.

- SCSP3/SCSL2/SCSP2
  Perform the following definition.
  - For I/O list engineering

Table A5.3-14 Builder definition (I/O list engineering) required when using optical ESB bus repeater module

Builder to be defined	Target	Definition
Node definition of IOM Definition Editor of AD Suite	Perform it for all connected I/O nodes that are extended through the optical ESB bus repeater modules. In SCSP3, perform it for all N-IO nodes that are connected with fiber-optic cable(s).	Set Optical ESB Bus Repeater-Extends Node Bus to Yes.
		Specify the ESB bus distance from the CPU node to the relevant node in Optical ESB Bus Repeater - Extends To.

  - For RS original engineering

Table A5.3-15 Builder definition (RS original engineering) required when using optical ESB bus repeater module

Builder to be defined	Target	Definition
I/O Parameter Builder	Perform it for all connected I/O nodes that are extended through the optical ESB bus repeater modules.	Set Extends Node Bus to Yes.
		Specify the ESB bus distance from the CPU node to the relevant node in Extends To.

  For the undefined node, communication errors may occur to the node. If this error occurs, the output modules may output the Output value at fault.

- SCSP1/SCSU1
  Perform the following definition.

Table A5.3-16 Builder definition required when using optical ESB bus repeater module

Builder to be defined	Definition
SCS Constants Builder	Set Optical ESB Bus Repeater to Yes.
	Specify the correct “Maximum extension distance of fiber-optic cable” in Maximum Extension Distance.
Use the Resource Properties dialog box. If the node extension distance exceeds 25 km and HART communication is performed periodically, the scan period must be changed.	Cycle Timing must be set to 100 ms or longer.

  - For I/O list engineering

Table A5.3-17 Builder definition (I/O list engineering) required when using optical ESB bus repeater module

Builder to be defined	Target	Definition
Node definition of IOM Definition Editor of AD Suite	Perform it for all connected I/O nodes that are extended through the optical ESB bus repeater modules.	Set Optical ESB Bus Repeater-Extends Node Bus to Yes.
		Specify the ESB bus distance from the CPU node to the relevant node in Optical ESB Bus Repeater - Extends To.

- For RS original engineering

Table A5.3-18 Builder definition (RS original engineering) required when using optical ESB bus repeater module

Builder to be defined	Target	Definition
I/O Parameter Builder	Perform it for all connected I/O nodes that are extended through the optical ESB bus repeater modules.	Set Extends Node Bus to Yes.
		Specify the ESB bus distance from the CPU node to the relevant node in Extends To.

In the undefined nodes, the system behaves as if the corresponding I/O node is located at the Maximum extension distance of fiber-optic cable. Although I/O modules function correctly, the CPU load fluctuation may become large if abnormalities occur. By performing definition, the CPU load fluctuation can be reduced at the time of abnormality.

- SCSV1
  Perform the following definition.

Table A5.3-19 Builder definition required when using optical ESB bus repeater module

Builder to be defined	Definition
SCS Constants Builder	Set Optical ESB Bus Repeater to Yes.
	Specify the correct “Maximum extension distance of fiber-optic cable” in Maximum Extension Distance.

Influence of ESB bus extension by optical ESB bus repeater devices

When the ESB bus is extended and installed by using optical ESB bus repeater, there is influence as follows: However, both the demand reaction time and fault reaction time are the same as those when I/O nodes are connected with non-optic ESB bus cables.

- The number of I/O modules and the amount of applications need to be adjusted according to the SCS load.
- The time required for IOM download becomes longer.
- ALR111, ALR121, or ALE111 for Modbus slave communication cannot be mounted on I/O nodes located at a distance of 5 km or further.
- For SCSP1/SCSU1 or SCSV1, the load on the CPU modules increases according to the maximum extension distance of fiber-optic cable.
- The time accuracies of SOE data (discrete inputs) vary according to the maximum extension distance of the optical fiber cable (except SCSV1). The following table shows influence.

Table A5.3-20 Time accuracies of SOE data (discrete inputs)

Maximum extension distance of fiber-optic cable	Time accuracies
Extension within 25 km	±2 ms
Extension from 25 km to 50 km	±3 ms

- When using a barrier for Digital Input, the delay time of the barrier will be added to the time precision.

SEE ALSO For more information about delay time of barrier, refer to:

Specifications and manual of barrier for Digital Input being used

A6. Inputs and outputs of SCS

This section describes the flow and processing of Analog I/O data and Digital I/O data (AIO/DIO data), and I/O variables in the SCS.

A6.1 Flow of AIO/DIO data

The following figure illustrates the flow of AIO/DIO data in an SCS.

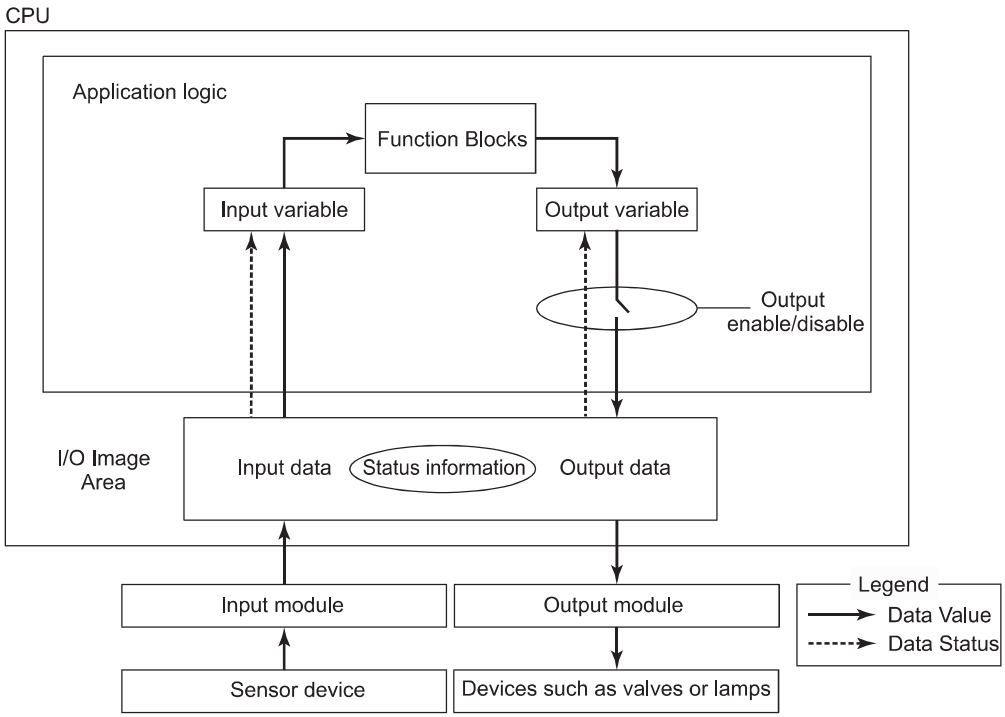

Figure A6.1-1 Flow of AIO/DIO data

1. Data sent from sensor devices or other sources is read from each channel of a connected input module.
2. The CPU copies the data stored in the input module to the I/O image area at the start of scanning. At this point, the data value and data status are determined based on the information from the input module. If the input data is erroneous, the data status is set to "BAD" and the data value is set to the "Input value at error occurrence" specified in an I/O parameter by the user.

TIP

The following I/O parameters are used for "Input value at error occurrence", which is used when input data is erroneous.

- [Input Processing at Fault] of AI and DI modules
- [Input Processing at Transmitter Fault] of an AI module

This manual uses the term "input value at error occurrence" in the following explanation as a generic term.

3. The CPU stores the input data in the I/O image area in the input variables of the application logic. It also updates the data status of the output variables.
4. The application logic references the data value and data status from the input variables and monitors the process conditions and input device status.
5. The result of the application logic processing is stored in the output variables and then sent to the output module via the I/O image area.
6. The output module outputs the data to devices such as valves or lamps connected to each of the channels.

Data value at AIO/DIO module dual-redundant configuration

If dual-redundant input modules are used, the input values from the active module are stored in the input variables. If dual-redundant output modules are used, the data values of the output variables are set to both active and standby modules, but the data is output to the field from only the active module. In the case of SDV526/L1DV526, the data values are output to the field from both modules.

Conversion of analog input data

Analog data of either 4 to 20 mA or 1 to 5 V/ 1 to 10 V is converted to normalized data of 0 to 100% in the CPU process data input processing and stored in the input variables.

All data that requires normalization, such as measurements from differential pressure transmitters, is automatically processed in the process data input processing in this way. Subsequent conversion from normalized data to data using engineering units can be performed freely in the application logic. Analog data of either thermocouple or resistance temperature detector is converted to the data (physical quantity or normalized data) specified in the input signal conversion for each channel and stored in the input variables.

Flow of analog output data

Data of 0 to 100% set in IO_REAL type output variables from the application logic are converted to electrical current of 4 to 20 mA by each output module and output.

Output enable and output disable

Output channels of an SCS can be in the Output Enable and Output Disable states. The Output Enable and Output Disable states are managed by each channel; the output states of all the output channels of an SCS do not always match.

- Output Enable is a status where the output values from the application logic are output from the output module as is.
- Output Disable is a status where the output values from the application logic are not output from the output module.

Output enable operation

Output enable operation means connecting outputs from the application logic to the output channels. If you perform the output enable operation from the I/O Channels Status dialog box of SCS Maintenance Support Tool on the SENG, all modules are placed in the Output Enable status simultaneously (not individually). Once the output enable operation is performed, all output channels are in the Output Enable status and output values of the application logic are output from the output channels. Channels that continue to generate errors remain in the Output Disable status. The following processing is also performed in the output enable operation implemented immediately after an SCS is started:

- Start sending data in inter-SCS safety communication
- Start SCS Link Transmission
- Start outputting data in subsystem communication

A6.2 I/O variable

This section explains the I/O variables, and their data value and the data status.

What are I/O variables?

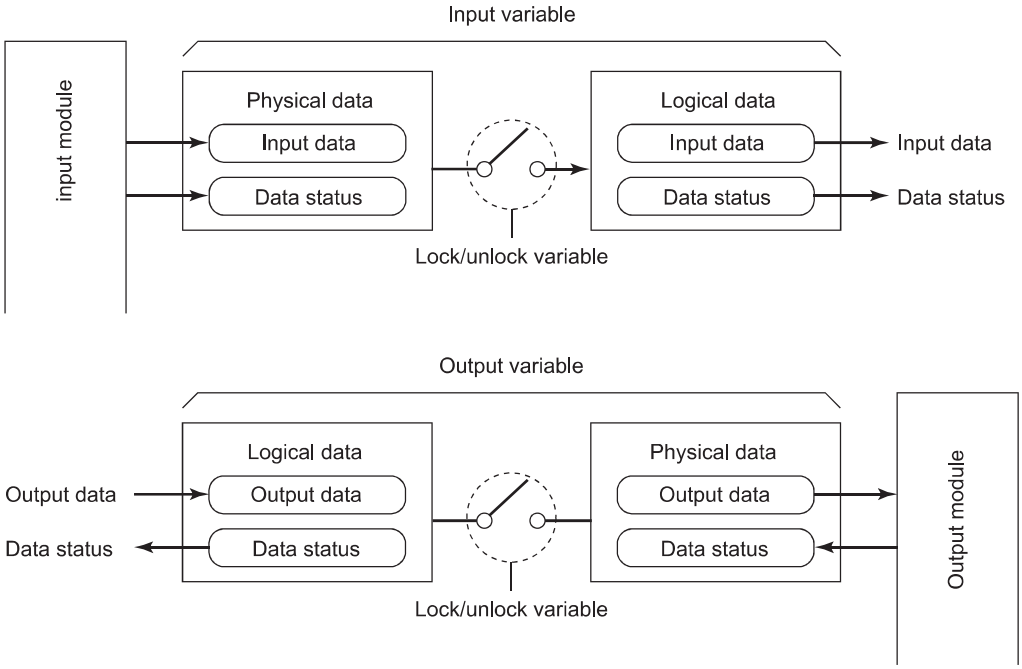

Figure A6.2-1 Input variable and output variable

The variables carrying the input values or output values of input/output modules are called I/O variables. There are two types of I/O variables: input variables and output variables. I/O variables contain two types of data, logical data and physical data. When I/O variables are defined, both logical data and physical data are automatically created.

Table A6.2-1 Input variable and output variable

Type	Data	Description
Input variable	Physical data	Data set from the I/O image area.
	Logical data	Data viewed by the application logic. (*1)
Output variable	Physical data	Data set in the I/O image. (*2)
	Logical data	Data set by the application logic.

*1: If the input data is erroneous, the input value at error specified by the user in advance is set.
*2: This is the value set to the output module.

The application logic can basically handle logical data only. In the normal status, the same data is stored in the logical data and physical data; the user does not need to be aware of the difference between these two types of data. Note, however, that physical data needs to be referenced from the SCS Manager window when locking I/O variables via the forcing function, or if both data are not connected due to input/output module failures, etc.

Both the logical data and physical data are composed of data value and data status. In order to handle data value and data status, I/O variables provide IO_BOOL type for handling BOOL-type data and IO_REAL type for handling real number-type data, which can be used according to the data type of the data value.

The data value and data status can be referenced using the application logic. Use the syntax "I/O variable name.v" and "I/O variable name.status" in order to read only the data value or the data status from an I/O variable, respectively.

Data status of I/O variables

The data status of I/O variables is expressed as a BOOL value.

Table A6.2-2 Data status that can be referenced by user applications

BOOL value	Status	Meaning
TRUE	GOOD	Status where no error has occurred in input/output modules. In the case of an input variable, this means the data value is from the field.
FALSE	BAD	This indicates that a normal data value cannot be obtained from or a value cannot be set to the I/O module due to failure of the module. In the case of an input variable, the data stored is the input value at error occurrence that is specified in an I/O parameter.

I/O variable condition and data value/data status

Timing at which data status is created

The data status of the I/O variables is created based on the I/O status information. If the I/O variables are not locked, the data statuses of the physical data and the logical data are the same. If the I/O variables are locked, only the data status of the physical data is updated.

In the case of an output variable, the update timing and transmission direction are different for the data value and the data status. Moreover, in the Output Disable status, the data values of the physical data and the logical data are different but the data status matches.

Lock/unlock status of I/O variables, Output Enable/Output Disable status and data value/data status in each status can be summarized as shown in the following tables.

Data value and data status of input variables

Table A6.2-3 Data value and data status of input variables

Status	Physical data	Logical data
Unlocked status (at normal input)	The data value takes the input value from an input module. The data status is GOOD.	The data value matches with that of the physical data. The data status matches with that of the physical data.
Unlocked status (at erroneous input)	The data value takes the input value from an input module. The previous value is maintained if there is no response. The data status is BAD.	The data value becomes the input value at error occurrence that is defined in an I/O parameter. The data status matches with that of the physical data.
Locked status	Same as for unlocked status for both the data value and data status	The data value and data status immediately before locking are retained. They can be changed from the SCS Manager.

Data value and data status of output variables

Table A6.2-4 Data value and data status of output variables

Status		Physical data	Logical data
Unlocked Status	Output Enabled	The data value matches with that of the logical data. The status of the output module is reflected in the data status at each interval.	The data value is set to the result of the application logic processing. The data status matches with that of the physical data.
	Output Disabled	The data value becomes the fail-safe value that is defined in an I/O parameter. The status of the output module is reflected in the data status at each interval.	

Continues on the next page

Table A6.2-4 Data value and data status of output variables (Table continued)

Status		Physical data	Logical data
Locked status	Output Enabled	The data retains the value immediately before locking and the value can be changed from the SCS Manager. The status of the output module is reflected in the data status at each interval.	The data value is set to the result of the application logic processing. The data status is retained immediately before locking and the status can be changed from the SCS Manager.
	Output Disabled	The data value retains the previous value. However, the fail-safe value is set by the CPU when the output is disabled. (The value can be changed from the SCS Manager.) The status of the output module is reflected in the data status at each interval.	

Logical data and physical data of analog output

The relationship of logical data and physical data of analog output is shown below. Analog output processing consists of discrete output operation, plus limiter processing and tight-shut/full-open processing.

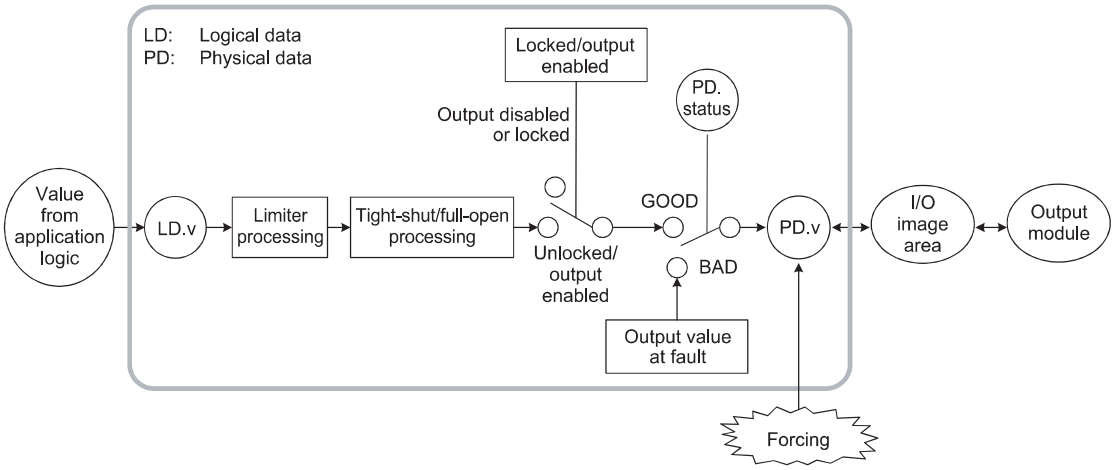

Figure A6.2-2 Flow of logical data and physical data of analog output

The following processing is performed until the logical data is output as physical data from the analog output module.

- Output is limited to a range of -17.19 to 118.75 [%].
- If tight-shut/full-open is specified, the tight-shut value is set when the logical data is 0.0 or below, or the full-open value is set when the data is 100.0 or above.
- If output is disabled or locked, the last physical data value is retained.
- If an error occurs, the Output value at fault is set or the last value is retained in accordance with the Output processing at fault.

Data status at AIO/DIO module dual-redundant configuration

In the case of dual-redundant input modules, the data status of each input variable is determined based on the I/O status information of the active input module. The same rule applies to dual-redundant output modules as well.

A6.3 High current output function

This high current output function combines consecutive DO channels of an N-IO I/O module, and supplies a large current to the connected devices. This function is used to connect to devices such as beacon and sounder.

You need to determine the number of channels to be used according to the current that is required by a connected device.

- Connecting to a device that requires a current of 1.3A: Use two consecutive channels
- Connecting to a device that requires a current of 2.0A: Use three consecutive channels

Combined channels can be categorized as primary channel and non-primary channel.

- Primary channel: The channel to which I/O variable can be assigned among the combined channels. This is the lowest number channel among the selected channels.
- Non-primary channel: The channel to which I/O variable cannot be assigned among the combined channels.

If an error occurs in the combined channels, it is notified as error in primary channels.

For example, if the channels are set to be combined on engineering, and if the combined channels are insufficient or their numbers are misplaced, it is notified as error due to open circuit in the primary channel. In this case, the output that is set in engineering becomes fail-safe value for both primary and non-primary channels in the same manner as in the output channel error. In addition, the primary channel will be in output disable status.

You need to specify the primary channel when you execute output enable operation and forcing function for the combined channels. A non-primary channel is handled in the same way as a channel that is not being used.

You can check the position of the faulty channel in the IOM Report.

IMPORTANT

The high current output function cannot be used when using an intrinsically safe barrier.

A7. Performance and scan period in the SCS

There are two types of scan periods of SCS, the scan period of the application logic execution function and the scan period of the external communication function. The scan period of the application logic execution function can be changed online.

SCS has the automatic extension function for the scan period of the application logic execution function. This function automatically extends the scan period of the application logic execution function when the load on SCS becomes high. Use the SCS Constants Builder to specify whether or not to use this function.

A7.1 Definition of SCS scan period

This section describes the definition of the SCS Scan period and how to define it.

Scan periods in SCS

The periodic processing for SCS falls into two types: Application Logic Execution Function and External Communication Function. They are executed at their respective scan periods.

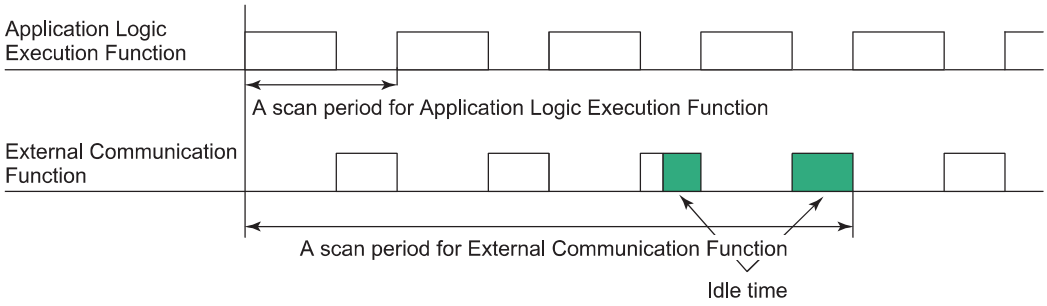

Figure A7.1-1 Scan periods of SCS

The Application Logic Execution Function is the function having a top priority among SCS functions.

The External Communication Function is executed in a part where the Application Logic Execution Function is not executed in the CPU processing period. If the External Communication Function finishes its processing before a scan period ends, the remaining time becomes the idle time on CPU.

Processing of the Application logic execution function

The Application Logic Execution Function is executed in the order presented as follows.

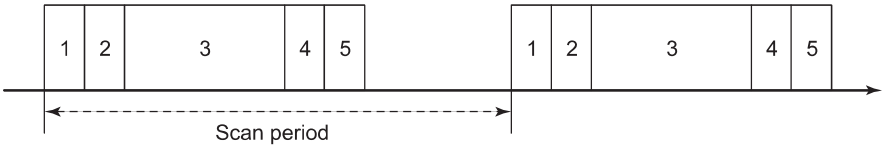

Figure A7.1-2 Processing of the Application logic execution function

Table A7.1-1 Processing of the Application logic execution function

Order	Processing Name	Description
1	Input AI/DI data, Self-diagnosis	Collects AI/DI data from input modules, and generates data values and data status. Stores the generated data in the input variables. Generates status of output modules and the self-diagnostics are also executed at the same time.
2	Receive data from other SCS	Receives the data from other SCSs, and stores them to the variables. (Applicable to inter-SCS safety communication and SCS link transmission)
3	Execute Application Logic	Executes application logic in FBD and LD.
4	Transmit Data to other SCS	Transmits data to other SCSs. (Applicable to inter-SCS safety communication and SCS link transmission)
5	Output AO/DO data, Self-diagnosis	Collects the data from output variables, and writes the data to the output modules. The self-diagnostic processing is executed at this timing.

The processing time of the Application Logic Execution Function may be prolonged by about 20% at maximum because of the increase in the CPU load caused by communication for tag data access or some other processing.

Processing of the external communication function

The External communication function is a general name for functions of communicating information of SCS with external systems. CENTUM Integration Function and Modbus Slave Communication Function are included in it.

Specification of scan period of the application logic execution function

The scan period of the application logic execution function is specified on the Link Architecture View of SCS Manager. From [Edit] > [Properties], Call the Resource Properties dialog box, enable the "Trigger cycles" check box in the "Settings" tab, and specify the value in "Cycle timing."

- The scan period can be specified in the range from 50 ms to 1000 ms in increments of 10 ms.
- The specified scan period can be changed online. (*1)

*1: Supported in the SCS of SCS system program R2.03 or later.

SEE ALSO For more information about Link Architecture View, refer to:

"Run-time Settings" in "Editing resource Properties" in "Link Architecture view" in "Workbench" in the Workbench User's Guide

Specification of scan period of the external communication function

The scan period of the external communication function is specified in the SCS Constants Builder. Specify the value in [Scan Period for External System] in the [Communication] tab.

- Either 1 second or 2 seconds can be specified.
- The default value is 1 second.
- Offline download is required to change the specified scan period.

Watching scan run time

While the SCS system program runs successfully, the Watch Dog Timer (WDT) is periodically reset. The WDT is for self-diagnosing the cyclic operations.

Confirmation of CPU processing time and consideration of idle time

CPU processing time

The actual processing time of the Application Logic Execution Function can be checked on the SCS State Management window of SENG or Status Display View of HIS. It can also be referred with the application logic by using the SYS_SCAN system function block.

Application execution time is the period of time required for processing the application logic within a scan period. Instantaneous value (%) in each scan calculated by 10 ms resolution is displayed.

CPU idle time is the period of time when the CPU has no task including the External Communication Function. Idle time per 60 seconds is displayed.

These displayed times tend to fluctuate depending on the communication load since the CPU of SCS processes the communication with SENG and communication requests from DCS.

Consideration of CPU idle time

You must confirm the above-mentioned Application Logic Execution time and CPU idle time when creating, adding, or changing an application logic for the SCS. The appropriate CPU idle time is necessary to ensure the external communication, the online change, etc.

You can take the following measures when the CPU idle time is insufficient.

- Reduce application logic.
- Lengthen the scan period.
- Divide application logic into two SCS.

Influence on application logics according to the increase of communication load

Processes on communication with SENG (online monitoring, I/O lock window operation, etc.) and communication request from DCS are done by the CPU of SCS so that they consume its idle time. Upon the increase of the frequency of such communication requests, SCS restricts the communication requests to accept to a certain amount. Thus those communications may be delayed.

Therefore when there is no communication, securing the idle time of the CPU to be more than 30 % is recommended to keep the influence on the communication to minimum upon the temporary increase of the communication load.

Influence when the execution load of the application logic is large

Even if the time taken for the processing of application logic execution occupies large portion of the SCS scan period and therefore CPU idle time is steadily less than 30%, the application logic can still be executed when there are no communications with SENG (online monitoring, I/O lock window operation, etc.) nor with DCS. However, if the communication load increases this situation, the following phenomenon will be observed.

- When the idle time is not sufficient
  - Updating the data displayed on HIS window, communication with SENG and FCS may be delayed.
  - Process alarms and annunciator alarm may be delayed.
  - Modbus slave communication may become an error.

  As the idle time lessens, the above phenomenon will become more obvious.
- When there is hardly any idle time and the application logic execution time is equal to scan period
  - Updating the data displayed on HIS window, communication with SENG and FCS may be stopped.
  - Sending process alarms and annunciator messages may be stopped.
  - Modbus slave communication may become an error.
- When there is no idle time and the application logic execution time is steadily longer than scan period
  - Inter-SCS safety communication will not be performed properly and timeout errors may be detected on the receiving side. Such phenomenon does not occur in SCS link transmission safety communication because the communication mechanism is different.

A7.2 Automatic extension function for scan period of the application logic execution function

In such a case as when the SCS has to perform very large amount of communication to access tag data, the processing time of the Application Logic Execution Function may be prolonged. If the amount of application is large and there is insufficient idle time before the next scan period starts, the SCS does not have sufficient time for the processing of communication on the control bus and for the External Communication Function that is done during the intervals between executions of the Application Logic Execution Function.

In such conditions, some functions such as the CENTUM integration function are affected. If high-load conditions continue steadily, inter-SCS safety communication may also be affected.

To avoid such adverse effects, you need to design the application logic so as to ensure the recommended CPU idle time given in the Engineering Guide.

If you anticipate that the SCS cannot maintain sufficient CPU idle time because of underestimating the amount of application logic at initial engineering or the modification of the SCS project, you can specify the use of the automatic scan period extension function in order to avoid the adverse effects (*1)

*1: Supported in the SCS of SCS system program R2.03 or later.

IMPORTANT

The purpose of this function is to temporarily avoid occurrences of erroneous conditions in SCS. SCS cannot maintain the assumed process safety time if the automatic scan period extension function is executed. Thus, take permanent measures such as reducing the amount of application logic in order to lower the CPU load on the SCS.

It is possible to check if the scan period has been automatically extended on the SENG or Status Display view of HIS as well as via diagnostic information messages. It is also possible to create application logic for confirming the state of scan period extension.

Automatic scan period extension function

The purpose of this function is to extend the scan period of the application logic automatically in order to prevent communication functions, such as inter-SCS safety communication, from stopping when the execution of application logic takes longer than the scan period defined in the SENG as a result of online changes of application software that contains engineering mistakes for example. This function can be enabled or disabled on the SCS Constants Builder. It is disabled by default.

IMPORTANT

If a demand occurs while scan period is extended, it can affect safety because, for example, the reaction time may become longer than the process safety time. You need to judge carefully whether or not to enable the automatic scan period extension, taking the process safety time into consideration. If the scan period is extended while the automatic scan period extension is enabled, promptly take countermeasures such as reducing the amount of application logic by online change.

Overview of automatic extension of scan period

If the processing of the Application logic Execution Function is prolonged and almost occupies the whole scan period of the Application logic Execution Function defined in SCS Manager, the SCS cannot perform the processing for the communication on the control bus and for the External Communication Function that is done during the intervals between executions of the Application Logic Execution Function.

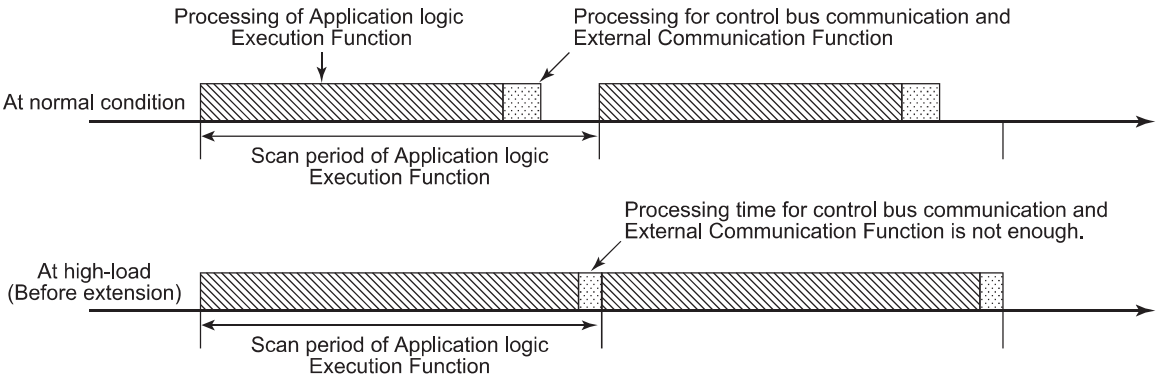

Figure A7.2-1 Example of the case when the scan period is automatically extended

The automatic scan period extension function automatically extends the scan period of the Application logic Execution Function when high-load conditions occur and ensures sufficient time for the processing of communication on the control bus and for the External Communication Function that is done during the intervals between executions of the application logic.

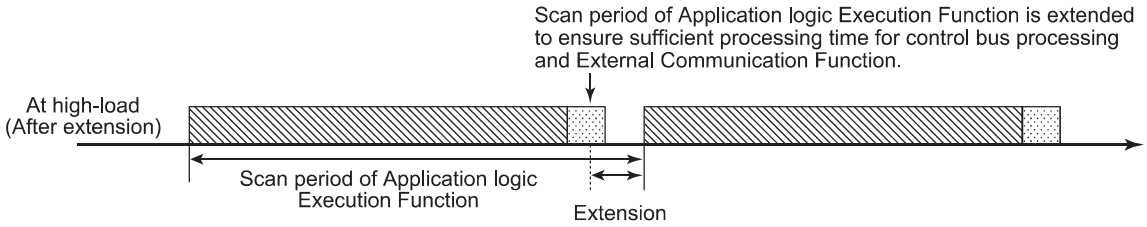

Figure A7.2-2 State in which the scan period is automatically extended

By using the automatic scan period extension function, the time for the communication processing related to the following features are ensured.

- Inter-SCS safety communication
- Integration with CENTUM
- Communication with SENG
- Diagnostic information message, process alarm notification

Conditions of starting scan period extension

When both of the following conditions are satisfied in a state at once, it is defined as a high load status.

- The total time to execute the application logic execution function and to process inter-SCS safety communications exceeds 80% of the original scan period of the application logic execution function.
- The CPU idle time becomes 0.

In this case, you can estimate the processing time for inter-SCS safety communication with the following formula:

```
Processing time for inter-SCS safety communication = (Number of consumer groups +
 Number of producer groups) x T [ms]
```

The values of T are as shown in the following table according to the configuration of the CPU module.

Table A7.2-1 Values of T

CPU module	T
SCP401/SCP451 (Dual-redundant)	5.0
SCP401/SCP451 (Single)	2.5
SCP461/S2CP471/L1CP471 (Dual-redundant)	3.0
SCP461/S2CP471/L1CP471 (Single)	1.5

If this high load status continues for 1 second or longer, the scan period of the application logic execution function is automatically extended.

The new scan time is obtained by adding 20% of the original scan period of the application logic execution function to the actual measurement of the application execution time at that time.

Influence until activation of scan period extension

The following situations may occur before the automatic scan period extension period is activated after the SCS is placed under high load status.

- Stopping of CENTUM integration data update
- Delay of diagnostic information message notification
- Stopping of forcing data update
- Stopping of status display in the SCS State Management window

Upper limit of scan period extension

The upper limit of scan period extension is 200% of the original scan period of the application logic execution function. Note that the extended scan period will never exceed the upper limit value of 1 second.

Cancellation of scan period extension

If both high load conditions explained in item "Conditions of Starting Scan Period Extension" are removed, the scan period becomes shorter by each scan in decrements of 20% of the original scan period of the application logic execution function. Note that the scan period will never become shorter than the scan period of the application logic execution function defined in SCS Manager.

Notification of execution/cancellation of automatic scan period extension

- If the automatic scan period extension function is activated on the SCS, it is notified via the diagnostic information message (No. 4143). The cancellation of extension is notified via the diagnostic information message of automatic scan period extension cancellation (No. 4144).
- If automatic scan period extension is continuously activated for a certain period of time or longer, the diagnostic information message indicating the start of the automatic scan period extension function is notified to give warning again. The re-warning interval is 10 minutes by default.

The interval of re-warning can be changed using the SYS_SCANEXT system function block.

- The system function block (SYS_SCANEXT) can be used to determine whether the automatic scan period extension function is being executed via application logic. (*1)
- If the scan period of the application logic execution function is changed via online change download while the scan period is being automatically extended, the scan period extension status is cancelled after the completion of the online change download and the diagnostic information message on cancellation of scan period automatic extension is notified. However, if the high CPU load continues even after the scan period is changed and if the conditions for automatic scan period extension are met, the scan period is extended automatically.
- The SCS State Management window of SENG and the Status Display view of HIS (*2) display both the scan period of the application logic execution function defined in SCS Manager and the actual scan period of the application logic execution function of SCS.

*1: The SYS_SCANEXT system function block can be used in new SCS databases created by SENG of R2.03.00 or later.
*2: Supported in CENTUM VP R4.02 or later.

SEE ALSO For more information about SYS_SCANEXT, refer to:

11.27, “SYS_SCANEXT (scan period extension indicator)” in POU Reference Manual (IM 32P03B20-01EN)

For more information about Diagnostic information messages, refer to:

Message Number 4143 in 2.1, “System Alarms (Message Numbers 4101 through 4222)” in Messages Reference Manual (IM 32P02B10-01EN)

Precautions when using Automatic scan period extension function

The fact that the SCS is running with an automatically extended scan period is important safety information. In projects where no HIS is connected, it is necessary to use the SYS_SCANEXT function block to notify the user that the SCS is running with an automatically extended scan period.

Influence of automatic extension of scan period

Automatic extension of the scan period has the following influence.

Influence on process safety time

Since the reaction time is determined based on the scan period of the application logic execution function, the time also becomes longer accordingly if the scan period is extended.

SEE ALSO For more information about precautions upon engineering related to automatic extension of scan period, refer to:

A7., “Performance and scan period in the SCS” on page A7-1

Influence on test functions

The automatic scan period extension function does not operate in SCS simulation tests and logic simulation tests.

Influence on Function Blocks

- SYS_SCAN function block
  The current scan period of the application logic execution function of SCS is output to the output parameter SCAN of the SYS_SCAN function Block.
- Function blocks handling time

There is no influence of changes in scan period on the operations of function blocks handling time. Those function blocks operate according to the actual time even if the scan period is changed.

- Function blocks handling execution count
  In the case of function blocks whose output is determined by the number of calls, the number of outputs within the unit time decreases if the scan period is extended.

  Targets: CTU, CTD, CTUD, FILTER, FILTER_S

A7.3 Locking of internal variables and performance in SCSP3/SCSL2/SCSP2

It is important to note that the application runtime becomes longer (i.e., the CPU load increases) if any internal variable is locked in SCSP3/SCSL2/SCSP2. You should lock internal variables for engineering and maintenance purposes only.

You must investigate whether there is a need to use the automatic extension function for scan period of the application logic execution function as a countermeasure to prevent high CPU load.

SEE ALSO For more information about automatic extension of the scan period of the application logic execution function, refer to:

A7.2, “Automatic extension function for scan period of the application logic execution function” on page A7-5

Internal variables that affect performance

Internal variables whose lock status affects the performance are those defined in the Dictionary. I/O variables and the variables that are locked in the Communication I/O Lock window, SCS Link Transmission Lock window and Inter-SCS Communication Lock window do not affect the performance.

Locking of internal variables

- In SCSP3/SCSL2/SCSP2, you can lock internal variables only when [Extend Scan Period Automatically] is set to [Yes], and [Locking of Internal Variables] is set to [Enable] in the SCS Constants Builder. If you need to lock internal variables, you need to set [Extend Scan Period Automatically] to [Yes], change [Locking of Internal Variables] to [Enable], and download to the SCS. Once the required lock operations are complete, you need to set these specifications back to the original settings and download to the SCS. Note that the locking of internal variables can be canceled regardless of these specifications.
- When the SCS security level is at Level 0, internal variables can be locked only if [Extend Scan Period Automatically] is set to [Yes], and [Locking of Internal Variables] is set to [Enable]. However, at Level 0, the application run time may get extended not only when the internal variables are locked, but also when the break point function of the application debugging function is used. If you use the break point function once, the application execution time does not return to the original length even if you cancel all break points.
- The locked internal variables can be checked with the diagnostic information messages of SENG or system alarm messages of HIS.

CPU load due to locking of internal variables

- If you lock internal variables when the CPU idle time is small, the execution time of the CPU may exceed the specified scan period. In such cases, the automatic scan period extension function may be activated in order to extend the scan period so that external communication processing and similar are not affected.
- Even if you lock one internal variable, the CPU load increases by 20% to 30% compared to the status where no internal variables are locked.(The rate of CPU load increase depends on the application)
- If you unlock all internal variables, the application execution time automatically returns to the original value before the internal variables are locked.
- It is recommended to set [Locking of internal variable] to [Disable] on the SCS Constants Builder while the SCS is running in normal operation. This is because there is a risk of

locking internal variables without considering the increase of CPU load if [Locking of Internal Variable] is set to [Enable].

A8. RAS (Reliability, Availability, Serviceability) functions of SCS

This section explains functions related to reliability, availability and serviceability of the SCS (hereinafter referred to as RAS in this manual). Moreover, it is a function that implements safety. The function includes the ability to shift to a safe state in a fast and reliable manner when an error occurs in the plant or system.

The RAS functions of the SCS are as follows:

- Operating mode
- Security level
- Diagnostic management function, diagnostic information messages
- Operation during start, and operation during error
- Dual redundancy

SEE ALSO For more information about SCS status monitoring functions, refer to:

H., “Monitoring the SCS status” on page H-1

For more information about Operations and recovery procedures during the SCS error occurrence, refer to:

G2., “Operations and recovery procedures during the SCS error occurrence” on page G2-1

Positioning of RAS function

RAS stands for Reliability, Availability and Serviceability, and is an important index when evaluating the system performance. Reliability means robustness against error occurrence, availability means shortness of downtime and serviceability means ease of repair at failure.

Functional relation of software

The RAS function diagnoses whether hardware and software are running normally and handles maintenance of them if any errors are detected. Since this function is able to shut the system down and change the SCS status as required, it is one of the most essential SCS functions.

Relationship with other hardware

The RAS function collects hardware error information concerning the I/O modules and other components in the station. The RAS function organizes hardware error information and executes pre-defined safety operations accordingly, such as shutting down. Error information is sent to the SENG and HIS as diagnostic information messages. The SCS saves diagnostic information generated internally. And the information can be referenced from SENG. You can delete saved diagnostic information messages from SENG.

The figure below shows how the RAS function of the SCS is positioned.

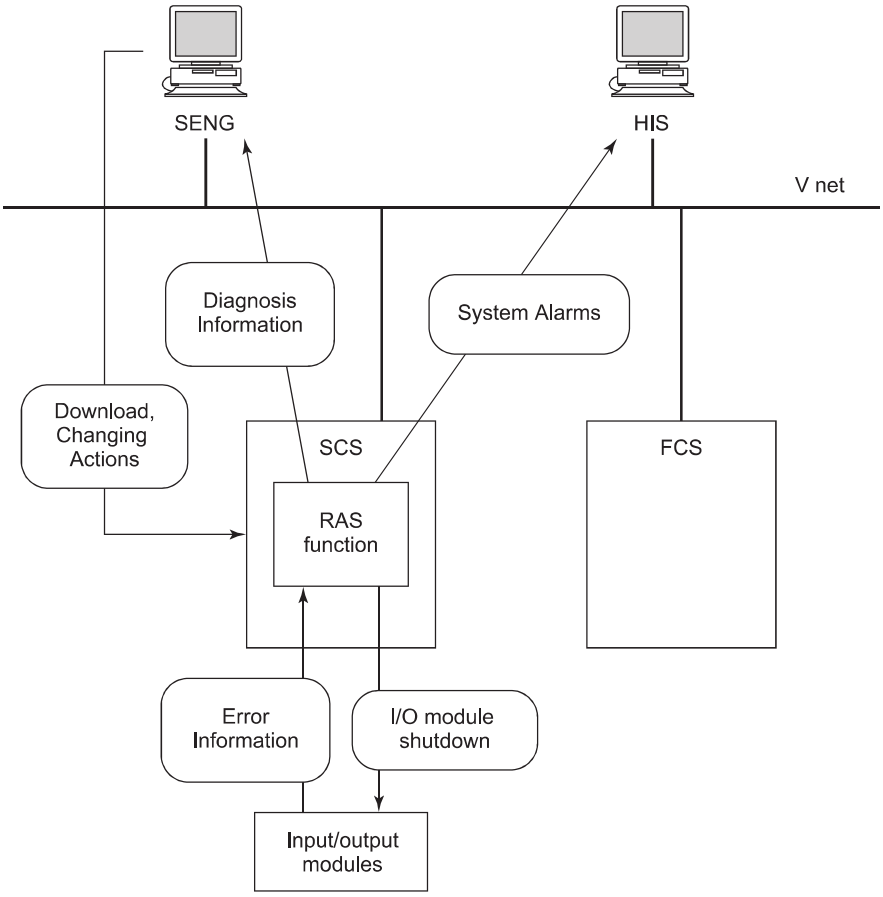

Figure A8-1 Positioning of RAS function

A8.1 SCS operating mode

The operating mode indicates the operation status of an SCS. Operations of the functions that are implemented by the system program of the SCS are determined by the operating mode. The operating mode is outlined as follows:

- The operating mode indicates the overall operating status of SCS, not the status of individual output modules.
- The operating mode indicates the status of a single SCS, regardless of whether the CPU configuration of the SCS is single or dual-redundant.
- For an SCS with dual-redundant CPU, the operating mode remains the same before and after a control right switchover of the CPU.

There are five SCS operating modes: Stop mode, Loading mode, Initial mode, Waiting mode, and Running mode

The following figure shows the transitions between operating modes. Note that it is possible to shift to the Stop mode from all other modes, but the arrows indicating these shifts are omitted for the sake of clarity.

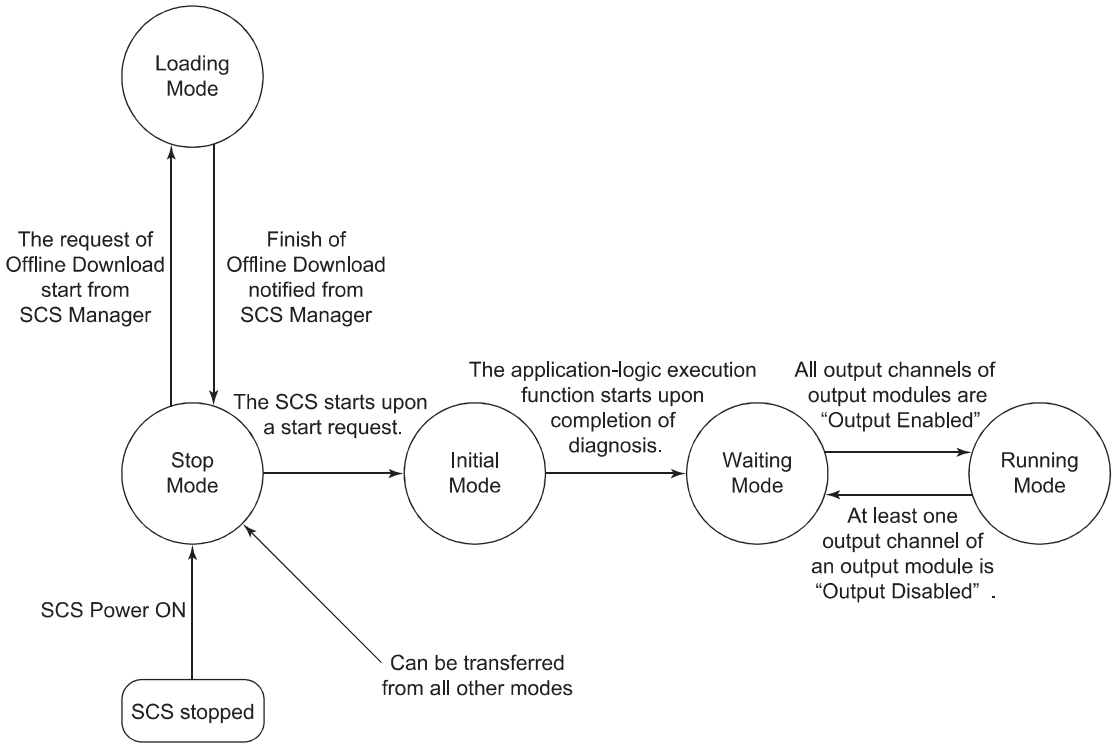

Figure A8.1-1 Transitions between operating modes

Stop mode (stopped status)

This is the initial state of the SCS.

Loading mode (during offline download)

In this mode, program and database are being downloaded from the SCS Manager to the SCS.

Initial mode (initializing status)

In this mode, the SCS is initializing databases, processing the diagnostic at startup, and starting the I/O modules as follows:

- Input modules
  If started successfully, input values are set to applicable input variables. If the startup of any module has failed, an error is recognized for the module.
- Output modules
  The outputs of all channels remain disabled after the startup is completed, so that the output values from the application logic will not be sent to the field immediately.
- Subsystem communication modules
  Receives only the input from subsystems while having an output that is invalid.
- Fire and gas communication modules
  If the startup process is successfully completed, fire and gas communication modules receive only the input from subsystems. If the startup process ends in an error, the SCS handles the fire and gas communication modules as erroneous.

Waiting mode (waiting for output enable request)

Application logic is periodically executed on each scan period. However, the output channel will not output the application logic value if the status is set to "Output Disable". The waiting mode status can be checked in the SCS State Management window and the LED display of the CPU module.

When "Output enable operation" is performed, the outputs on the normal channels of output modules are enabled. If you execute the "Output enable operation" just after starting up the SCS, the SCS also enables the output of inter-SCS safety communication, SCS link transmission and subsystem communication.

TIP

- Failure on the output channel should be removed, then perform "Output enable operation".
- Even when the channel is set to "Output Disabled", if the physical data is rewritten using the forcing function, the output value from the output channel changes.

SEE ALSO

For more information about the output enable operation, refer to:

C8., “Output enable operation” on page C8-1

For more information about relationship between forcing function and I/O variable data value/data status, refer to:

“■ I/O variable condition and data value/data status” on page A6-5

Running mode (controlling status)

This mode indicates that the SCS is running normally. All output channels of output modules are outputting the output values from the application logic. The Running mode status can be checked with the SCS State Management Window and LED display of the CPU module.

Output status monitoring

All output channels of output modules are monitored. If any of the channels becomes Output Disable status due to a failure in the corresponding module or in the output channel itself, or after adding new channels during online modification, the SCS will change its operating mode to the Waiting mode. The operating mode changes to the Running mode when the cause of the channel failure is removed, the output enable operation is completed and all output channels are placed in the Output Enable status.

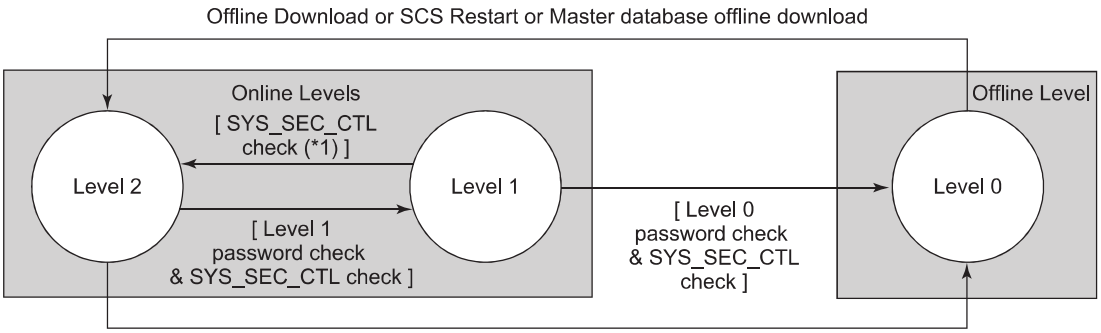
Checking of operation mode

The operating mode of SCS can be checked with the following methods.

- It is possible to check that the operating mode is either the Waiting or Running mode with the SCS State Management window of the SCS Maintenance Support Tool, the SCS Status Display view of HIS and the LED display of a CPU module.
- If the operating mode is either the Waiting or Running mode, the operating mode can be referenced from the application logic as well.

Influence on operating mode

Engineering and occurrence of errors can affect the operating mode as follows.



- The operating mode is not affected even if a subsystem communication error, safety subsystem communication error, or communication module error occurs.
- Occurrence of errors in SCS link transmission has no influence on the operating mode.
- If output modules/channels are added via online change download, the added modules/channels are started from the Output Disable status. If the operation mode was Running mode previously, it changes to Waiting mode. Perform the output enable operation.
- If channels in the Output Disable status or output modules that include such channels are deleted via online changes and there are no longer any channels in the Output Disable status in SCS, the operating mode shifts from Waiting mode to Running mode.
- If a single output module is changed to dual redundant configuration by online change download, IOM download is executed in order to initialize the modules. The outputs of the target modules become disabled after downloading. Since some channels are in the Output Disable status, the operating mode of SCS shifts to the Waiting mode. Perform the output enable operation after the output modules recover to normal.
- It is possible to perform the output enable operation regardless of the status of communication modules.
- It is possible to perform the output enable operation even if the status of communication with sub-systems is BAD. In this case, only outputs that are ready to communicate will start.

A8.2 Security level of SCS

The security level of SCS indicates the level of protection against erroneous writing to the memory in SCS from the connected stations or devices. An overview of SCS security level is as follows:

- One SCS has one security level.
- The security level can be confirmed from LED on the CPU module and the SCS State Management window of SCS Maintenance Support Tool or Status Display View of HIS.
- SCS limits changes made from the outside according to security level.
- Security level can be referred to by applicable logic.
- Security level can be changed by an authorized user with the password using the SCS Manager.
- Using the system function block (SYS_SEC_CTL) makes it possible to control whether or not to allow security level change operations from an SENG with an external hardware switch or similar.
- Security level can be changed under the following conditions:
  - The SCS is either in the Waiting or Running mode, AND
  - The SYS_SEC_CTL is set to allow security level changes or is not used.

The following figure illustrates the transition of states of the security level.

*1: It is allowed to reset the security level from Level 1 to Level 2 via the RST input in the SYS_SECURE block, regardless of the security level change enable/disable status of SYS_SEC_CTL.

Figure A8.2-1 Transition of security level status

Definition of each security level

There are two classifications of levels; online level and offline level. The Online level is used when SCS is in normal operation. The Offline level is used when SCS is not in normal operation.

Online level

The Online Level is a security level to be used when normal operation is performed in SCS. The SCS itself provides security of the Online Level by controlling access to the memory from the outside.

The Online Level is separated into two levels according to limits of functions which can be used.

Table A8.2-1 Online level

Level	Description
Level 2	The highest security level. SCS is usually operated at this security level.
Level 1	A temporary security level used by engineers or authorized users for maintenance of equipment or changing applications online

Offline level

The Offline Level is a security level to be used when a regular operation is not performed in SCS. This is displayed as "Level 0" on the LED of SCS or the SCS State Management window of SENG. In the Offline Level, SCS does not limit access to SCS from the outside. However, information which was used at test may be stored in SCS databases depending on operations performed by those tools.

IMPORTANT

To restore an SCS to Online Level from Offline Level, restart the SCS or do offline download. This ensures that the system returns to the security level for normal operation.

Relationship of operational items with SCS security levels

The following are the list of operational items in each security level. It is also possible to write information which is not related to any reference or safety function of the SCS, at any level.

Table A8.2-2 SCS related operations and the required security levels

SCS related writing operation	Security level (*1)			Operation side
	Level 2	Level 1	Level 0	
Override from HIS	OK	OK	OK	HIS
Operation for password block from HIS	OK	OK	OK	HIS
Operation for manual operation block	OK	OK	OK	HIS
Executing the reset function of a function block for fire and gas devices from HIS	OK	OK	OK	HIS
Confirmation of process alarm	OK	OK	OK	HIS
Setting operation mark on mapping block/mapping element	OK	OK	OK	HIS
Confirming and deleting the diagnostic information	OK	OK	OK	SENG
Setting Vnet time	OK	OK	OK	HIS/SENG
Change of security level	OK	OK	ERROR	SENG
IOM Download (*2)	OK	OK	OK	SENG
Resetting of trip signal file	OK	OK	OK	SENG
Change of passwords for security level	OK	OK	OK	SENG
Locking/unlocking of variables	ERROR	OK	OK	SENG
On-demand communication for device management	OK	OK	OK	PRM
Change of variable value with forcing function	ERROR	OK	OK	SENG
Online change of applications	ERROR	OK	OK	SENG
I/O lock function	ERROR	OK	OK	SENG
Communication I/O lock function	ERROR	OK	OK	SENG
Switching control right for redundant AIO/DIO modules	ERROR	OK	OK	SENG

Continues on the next page

Table A8.2-2 SCS related operations and the required security levels (Table continued)

SCS related writing operation	Security level (*1)			Operation side
	Level 2	Level 1	Level 0	
Enabling NIU maintenance port (*3)	ERROR	OK	OK	SENG
Offline download	ERROR	ERROR	OK	SENG
Application debugging function	ERROR	ERROR	OK	SENG
Restarting the SCS from SENG	ERROR	ERROR	OK	SENG
Output enable operation	OK	OK	OK	SENG
Save/download operation marks	OK	OK	OK	SENG
Start output module operation	OK	OK	OK	SENG
Locking and unlocking variables, changing variable values, and locking I/O by using iDefine	ERROR	ERROR	OK	iDefine

*1: OK: Operation allowed
ERROR: Operation failed
*2: You can download only on failed I/O modules.
*3: Can run only SCSP3 which supports NIU maintenance.

Security level at the start of SCS

The security level is Level 2 when SCS starts normally.

Operation of security level

Change operation of security level

To change the security level from Level 2 to Level 1 or to Level 0 or from Level 1 to Level 0, entering a password from SENG is required. When the security level is changed, SCS notifies the user of the change of the security level with the Diagnostic Information Message.

You can change the security level from Level 1 to Level 2 without a password. To change the security level from Level 0 to Level 2, you must restart the SCS.

Protection of security level by hardware switch

It is possible to use SYS_SEC_CTL to control whether or not to allow changing the security level from a SENG using an external hardware switch or similar.

- When the SYS_SEC_CTL is used, it is not allowed to change security level by password entry from SENG if the FIX parameter input of the SYS_SEC_CTL is set to TRUE. To change the security level of the SCS, the user needs to operate an external key switch or similar and change to the status where security level change operations are allowed (set the FIX parameter of the SYS_SEC_CTL to FALSE), and enter the appropriate password from a SENG.
- The SYS_SEC_CTL also controls whether it is allowed to reset the security level from Level 1 to Level 2 (even though password entry is not required).
- If the security change enable/disable status is changed by the SYS_SEC_CTL, the status is notified to user via a diagnostic information message.
- Resetting of the security level to Level 2 via RST input in the SYS_SECURE block and resetting of the security level to Level 2 via the CPU's restart switch are not affected by the security change enable/disable status of the SYS_SEC_CTL.

IMPORTANT

The situation when the FIX parameter of the SYS_SEC_CTL is constantly set to TRUE by erroneous applications should be surely avoided.

Reset function for security level

When a fault occurs in SENG or the communication line while the security level (Level 1) is being changed, it is required to reset the security level (back to Level 2) as soon as possible to ensure security of SCS. The SYS_SECURE block in the application logic can reset the security level with RST input.

- It is possible to reset from Level 1 in the SYS_SECURE block, not from Level 0.
- Connecting a discrete input signal to RST makes it possible to reset the security level with a key switch or a button. When this is not necessary, set FALSE to RST.
- The SYS_SECURE block detects the change of RST input from FALSE to TRUE and resets the security level.

Monitoring function of security level

When the security level of an SCS is in Level 1, the SYS_SECURE block monitors duration of the status. If the status of Level 1 continues longer than the time specified by the CHKT input in the SYS_SECURE block, a diagnostic information message occurs. After notifying the diagnostic information message, the duration is monitored again. The status of Level 0 is not monitored.

The following figure shows an example of application using the SYS_SECURE.

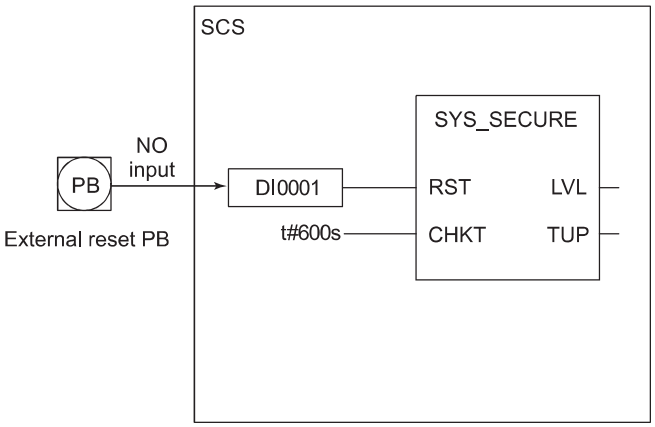


Figure A8.2-2 Example of application using security block

Passwords for changing security level

Specification for passwords

- Passwords for the security level are controlled in SCS.
- A password for the security level is set for each security level.
  It is necessary to set the password to change to Level 1 and Level 0 respectively. A password is not necessary to change to Level 2.
- A password is a maximum 16 of single-byte alphanumeric characters and following symbols including a space character. The password is case-sensitive.
  ! " # $ % & ' ( ) * + , - . / : ; < = > ? @ [¥] ^ _ ` { | } ~
- Passwords are maintained during a power cut and restart of SCS.
- Passwords are deleted by SCS offline download.

Setting and changing passwords

- Change passwords on the SCS Manager in SENG.
- Passwords can be changed when SCS is in operation.

- To change a password, user must enter the old password before it is changed.
- When a password has been changed, SCS notifies its change with the Diagnostic Information Message.

SEE ALSO For more information about operations for changing the SCS security level and setting the password, refer to:

B3., “Security of SCS” in ProSafe-RS User’s Guide (IM 32P01B10-01EN)

Precautions when changing SCS security level

- Set different passwords for each SCS.
- Set a different password for each security level.
- When the security Level of SCS has been changed, confirm that the change is made to an appropriate level with the SCS State Management Window.
- Do not set the security levels to Level 1 or Level 0 for several SCSs at the same time when SCSs are in operation.
- If setting a password to SCS during APC (All Program Copy), APC restarts. It takes about 10 minutes from setting a password, after offline download, to restarting the operation of the dual-redundant system.
  Do not change passwords during APC except the changes required for after offline download.

IMPORTANT

- When a password is not set, entering characters in the Password Entry Dialog causes an error. Considering safety as the safety system, always set passwords to use.
- Power failure or restart does not change or delete passwords.
- Passwords are deleted when offline download is performed. As there is no password after offline download, set new passwords after performing offline download.
- Passwords cannot be referred to after setting them. User should remember the set password. Also, Password should be controlled so that unauthorized users do not know it.

Precautions when using the SYS_SEC_CTL

The SYS_SEC_CTL block can control whether or not to enable the security level change by password entry from SENG. In general, an application containing the following blocks should be created.

Figure A8.2-3 General application example

Connect the toggle switch signal for controlling the security level change output from a DI module to the FIX parameter input of the SYS_SEC_CTL block. This makes it possible to switch the security change permission status via the external toggle switch. By connecting the output parameter to a lamp or similar, the security level change permission status can be displayed on an external device.

If the external toggle switch is connected to SYS_SEC_CTL, make sure to examine all possible states of the DI module or channel to which the toggle switch signal is input.

If an error occurs in the DI module or channel, SYS_SEC_CTL controls the security level change permission status as follows according to the setting of the I/O parameter Input Processing at Fault.

Table A8.2-3 Security level change control operations

Input Processing at Fault	Operation at Errors
1 (TRUE)	Changing security level by password entry via a SENG is disabled until the fault is corrected. (*1) If a fault occurs in Level 1, it is possible to reset to the same security level by the SYS_SECURE block (*2) or reset to Level 2 by restarting the SCS. It is, however, not possible to change to a lower level until the fault is corrected. (*3)(*4)
0 (FALSE)	During a fault, it is possible to change security level by password entry via a SENG.
HOLD	The operation performed before the fault occurred resumes. In other words, if an error occurs in the status where security change is unavailable (FIX is set to TRUE), the status where security change is not allowed is retained after the error occurrence. If an error occurs in the status where security change is allowed (FIX is set to FALSE), the status where security change is allowed is retained after the error occurrence. If an error occurs in the status where security change is unavailable (FIX is set to TRUE), it is necessary to take the same precautions as when inputting TRUE at Input Processing at Fault.

*1: Do not lock the input/output variables connected to FIX and change the security level to Level 2. The variables will not be unlocked even after the causes of errors are removed. (In this case, it is necessary to restart the SCS or reset by SYS_FORCE.)
*2: Use separate DI modules for the DI module for inputting the reset signal of the SYS_SECURE block and the DI module for inputting a toggle switch for security control of the SYS_SEC_CTL block.
*3: It is not necessary to lower the security level during recovery operations. If a DI module fails, replace the module and perform IOM download.
*4: It is necessary to take measures such as incorporating an application in order to avoid situations where the security level cannot be reset to Level 2 due to DI module errors when the security level is Level 1.

A8.3 Operations at SCS startup

An SCS always performs the initial cold start processing when it starts up. It does not have a function that allows it to resume the operating mode it was in before stopping. The operating mode at startup is always the Stop mode.

SEE ALSO For more information about Operating mode, refer to:

A8.1, “SCS operating mode” on page A8-3

Types of SCS startup methods

An SCS can start up in one of the following three ways.

Power recovery start

An SCS starts up in this way when the power supply is resumed after power failure.

Start after offline download

An SCS starts up in this way when the user performs offline download from the SCS manager.

Manual restart

An SCS restarts when the restart switch of the CPU module is pressed or the user performs SCS restart operation from SCS Manager of the SENG.

TIP

- After starting SCS, the operation requests from the SENG and Workbench will be ignored until the operating mode of the SCS changes to Waiting mode. The same error will occur to the communications with FCS or HIS for the CENTUM integration as well as Modbus slave communication. The operating mode of the SCS can be checked on the SCS State Management Window or identified through the LED of the SCS CPU module.
- A diagnostic information message notifying a failure/recovery may generate twice when the SCS is restarted. This does not present any problem in practical operations or on safety.

Internal data at SCS startup

Since an SCS always performs initial cold start when it starts up, all operation areas and variable values maintained dynamically by the SCS are initialized. System programs and databases that were downloaded offline and changes made online are saved in the flash memory and restored at start up.

Moreover, when the SCS is started, data saved in the NVRAM (nonvolatile RAM) may remain without being initialized.

The following are examples of data stored in the NVRAM (nonvolatile RAM):

- System log information
- Diagnostic information (200)
- SOE data log information (1000)
- Retainable data (SCSU1 only)

Table A8.3-1 Data status when starting SCS

Data stored in...	Data in SCS	Started after offline download	Started after power is restored/Manually restarted
Main memory	Variable in application logic	Initial value	Initial value
	Data in function block	Function block performs initialization	Function block performs initialization
	Security level	Level 2	Level 2
	Lock status of the variable	Reset	Reset
	Data of CENTUM integration function	Initial value	Initial value
Flash memory (*1)	System program	Loaded programs	Returns to the program used before the outage/stoppage.
	Database	Loaded database	Returns to the database used before the outage/stoppage.
	Contents of online modification		Changes made before the outage/stoppage are still valid.
	Password for changing the security level	The password used before loading is invalid (should be initialized).	The password used before the outage/stoppage are still valid.
NVRAM (nonvolatile RAM) (*2)	Specific log information	The log information before loading is not initialized.	The log information before outage/stoppage is not initialized.
	Retainable data	Initial value (*3)	The retained data before outage/stoppage is not initialized, but the data will be restored after SCS is started.

*1: This assumes that you have written into the flash memory.
*2: For the CPU modules with a battery on/off switch, NVRAM (nonvolatile RAM) is initialized if the power supply to the SCS is lost while the battery has a problem.
*3: It will not be initialized for master database offline download.

System alarms for the Inter-SCS safety communications and link transmission at the SCS startup

During SCS startup, no system alarm is raised for an error in the inter-SCS safety communications and SCS link transmission. System alarm is sent for the first error after the startup procedure and the error during the startup procedure turns to normal. System alarms related to inter-SCS safety communications and SCS link transmission are sent from the receiving station only.

At SCS startup, make sure that both the inter-SCS safety communications and link transmission are normal.

Do the following to check the normalcy:

- Check the communication status of the receiving function block (NR status of CONS FB, STS of LTRCV FB, and STS of LTFCS FB).
- Check the CMER of the system function block, SYS_DIAG.

A8.4 Diagnostic information management

The SCS detects hardware and software errors through self-diagnosis. It also notifies and saves diagnostic information by using the diagnostic management function. This section explains the diagnostic management function of the SCS.

Overview of self-diagnosis of SCS and diagnostic management function

An SCS performs self-diagnosis regularly to detect hardware and software errors. It analyzes detected errors and system configuration to determine the error level according to the error occurred and executes error-handling operations according to the error level.

The diagnostic management function saves/manages diagnostic information messages generated by self-diagnosis and manages the SCS status. Moreover, it notifies the operation status of the SCS to the SENG and HIS.

Functional relation of diagnostic management function

The following figure illustrates the flow of error information detected by the SCS diagnostic functions. Error information is composed of SCS statuses indicating faulty locations/error causes and diagnostic information messages used to notify the user about the errors. In the case of a CENTUM integration structure, the HIS treats diagnostic information messages as system alarms.

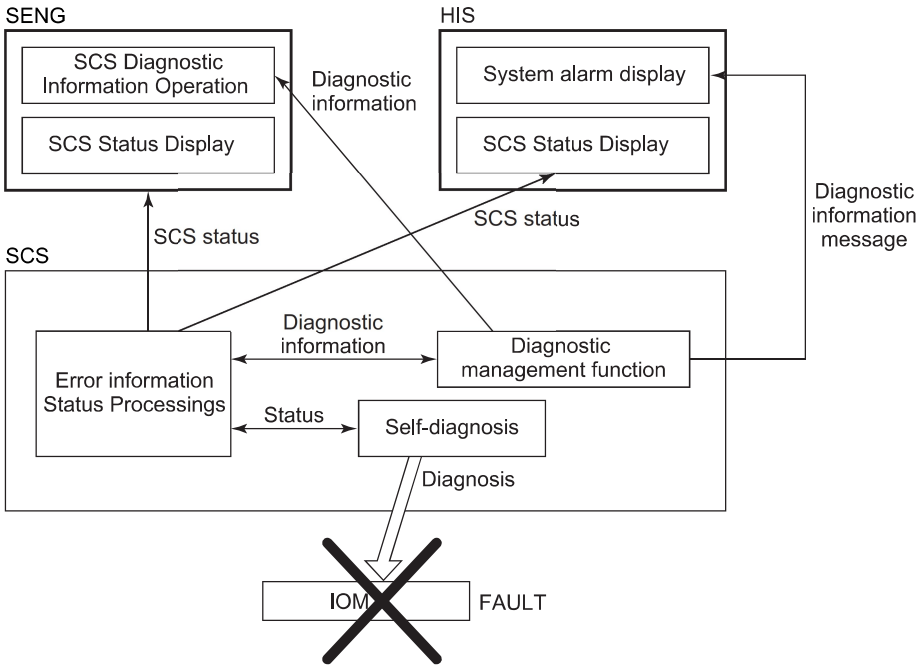

Figure A8.4-1 Functions related to SCS error information and flow of information

Management of diagnostic information

An SCS manages diagnostic information in the following manner.

- The SCS saves diagnostic information messages it sends in its memory as diagnostic information. It sends the saved message information in response to requests from SENG windows that handle diagnostic information.
- The buffer in the SCS that stores diagnostic information message has the capacity limit. In order to save all diagnostic information messages, it is necessary to collect diagnostic information messages from the SENG. The SCS can save up to 5000 diagnostic informa-

tion messages. If the SCS buffer becomes full, diagnostic information messages are deleted starting from the oldest one.

- In the event of power failure, the SCS saves the latest diagnostic information in the NVRAM (nonvolatile RAM). It will restore the saved information upon restart.

Notification of SCS diagnostic information

The diagnostic management function notifies SCS diagnostic information in response to requests from windows that handle diagnostic information. This allows checking and manipulating the information from the SENG and HIS.

- It is possible to check diagnostic information for each failed part from the Diagnostic Information Window of the SENG.
- It is possible to acknowledge/delete diagnostic information messages from the Diagnostic Information Window of the SENG.
- It is possible to see diagnostic information as a list of system alarm messages in SOE Viewer of the SENG and HIS.
- It is possible to check the state of the SCS, including how the CPU module is operating in the SCS Report dialog box of the SCS State Management Window of the SENG.

Notification of diagnostic information to Function Blocks

System status function blocks notify errors that are detected by the system diagnosis. As a result, you can make an application logic that uses the diagnostic information as reference and takes action when errors occur.

SEE ALSO

For more information about Safety system function blocks, refer to:

11., “Safety system function blocks” in POU Reference Manual (IM 32P03B20-01EN)

For more information about interference-free system function blocks, refer to:

12., “Interference-free system function blocks” in POU Reference Manual (IM 32P03B20-01EN)

A8.5 Diagnosis for hardware

The SCS carries out diagnosis at the following timing to check whether various types of hardware including I/O modules are in the normal state:

- At the start of the hardware
- At specified periodical intervals during operation

This section describes the HKU function in the CPU module, and the cabinet status monitoring function in the N-IO node.

HKU (House Keeping Unit)

The HKU function in the CPU module monitors the operation environment of the CPU module. An error in the CPU operating environment is notified to the user via diagnostic information messages and status display window. The following items are monitored by the HKU function.

- Fan status in the safety control unit
- Surrounding temperature of the safety control unit
- Battery temperature

Cabinet status monitoring

The N-ESB bus module of N-IO node monitors the operating environment of the cabinet. An error in the operating environment of the cabinet is notified to the user via diagnostic information messages and status display window.

Temperature monitoring

The SCS monitors the surrounding temperature of the N-ESB module, as well as the upper limit and lower limit value in the hardware. It monitors whether the temperature exceeds the prescribed value or not.

Power supply diagnosis

The SCS monitors the status of the power supply unit (PSU) connected to the N-ESB module unit. The following are the methods in diagnosing a power supply:

- PSU output stop diagnosis
  The SCS monitors the output voltage in redundant PSUs. It is judged as an error if output in either of the PSUs stops.
- Output over-voltage diagnosis
  The SCS monitors the output voltage of the PSUs, as well as the upper limit and lower limit value in the hardware. It monitors whether the output voltage exceeds the prescribed value or not. It is judged as an error if it exceeds the maximum value.

Input monitoring from external devices

By inputting a single point of discrete signal from an external device, which can detect power supply and fan abnormalities, in an external alarm input of the base plate, errors from the external device can be notified.

The safety control unit outputs the diagnostic information message according to the discrete signal that is inputted from the external device.

Because this function is interference-free, it cannot be used for safety logic.

A8.6 Dual-redundancy in the SCS

ProSafe-RS supports dual-redundant configurations of SCS CPU modules and input/output modules. With the dual-redundant configuration, the continuous controllability and operating efficiency can be improved. Moreover, with dual-redundantly configured hardware, the continuity of plant safety monitoring will be guaranteed by switching the control rights when an error occurs in the SCS hardware.

A8.6.1 Redundant configuration in SCS

In SCS, redundant configuration can be selected for the CPU module and I/O modules. The control bus, power supply module, ESB bus, ESB bus interface module, optical ESB bus repeater module, N-ESB bus, N-ESB bus module, and F-SB bus are always in redundant configurations.

CPU module

- The CPU module on the standby side performs the same control processing as the control side even while it is in the standby status. For this reason, it is possible to take over outputting data immediately after the control right is switched. Moreover, the operating mode of the SCS does not change.
- Only the CPU on the control side accesses the hardware composing the SCS and the CPU on the standby side always sets the equivalent value as the processing result. Therefore, the CPU modules on both sides always perform processing using the same data.
- In redundant configuration, if the CPU module on the standby side is not in the STBY status and the control right cannot be switched, the same operation as single configuration CPU module is performed.
- SOE data related to discrete inputs might be lost when the control right is switched between the CPU modules.
- With the CPU module of SCSL2 and the CPU module of SCSP2, the data loaded with the previous scan may be used instead of updating the data with the value from the input module when performing a scan immediately after a control right switchover of the CPU. Also note that data loaded from 1 or 2 scans earlier may be used with subsystem communication modules.
- With the CPU module of SCSP3, the data loaded with the previous scan may be used instead of updating the data with the value from the input module or fire and gas communication module when performing a scan immediately after a control right switchover of the CPU. Also note that data loaded from 1 or 2 scans earlier may be used with subsystem communication modules.

FIO I/O modules

Redundant configuration is possible in the FIO node(*1) by mounting the same type of FIO I/O module to two adjacent slots. In the case of redundant configuration, one side becomes the control side and the other becomes the standby side. Switching of the control right is performed by input/output modules. The switching has no influence on the application logic.

*1: An odd-numbered slot and the even-numbered slot obtained by adding 1 to the odd slot number

- It is not allowed to have redundant configuration across two nodes.
- SOE data related to discrete inputs might be lost when the control right is switched between the input modules even though the frequency is low.
- A HART communication error may occur when the control right is switched between analog input/output modules that support HART communication.

Table A8.6.1-1 Operation of redundant AIO/DIO modules

AIO/DIO module	Redundant operation
Analog input module Digital input module	The input data of the input module on the control side is stored in the input variable.

Continues on the next page

Table A8.6.1-1 Operation of redundant AIO/DIO modules (Table continued)

AIO/DIO module	Redundant operation
Analog output module Digital output module	The SCS outputs the same value for output modules on both the control and standby sides. Only the output module on the control side outputs signals to the field. If an error occurs on the module on the control side, the control right is switched and outputting is continued

SEE ALSO For more information about duplexing subsystem communication, refer to:

D1.2, “Dual-redundant communication” in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

NIO I/O modules

Redundant configuration is possible in the N-IO node by mounting the same type of N-IO I/O module to two adjacent slots. In the case of redundant configuration, one side becomes the control side and the other becomes the standby side. Switching of the control right is performed by input/output modules. The switching has no influence on the application logic.

- SOE data related to discrete inputs might be lost when the control right is switched between the input modules even though the frequency is low.
- A HART communication error may occur when the control right is switched between analog input/output modules that support HART communication.

Table A8.6.1-2 Redundant operation in N-IO I/O modules

Signal type	Redundant operation
AI/DI	The input data of the input module on the control side is stored in the input variable.
AO/DO	The SCS outputs the same value for output modules on both the control and standby sides. Only the output module on the control side outputs signals to the field. If an error occurs on the module on the control side, the control right is switched and outputting is continued

Optical ESB bus repeater module

The optical ESB bus repeater modules are always used in a redundant configuration.

Power supply module

A redundant power supply module is installed on each of CPU nodes, I/O nodes, and N-IO nodes of the SCS. The SCS monitors the status of the power supply at regular intervals and, if an error occurs, it notifies the user about the error via the SCS State Management window of the SENG, the Status Display view of the HIS, and diagnostic information messages. If one of the two power supplies mounted on the CPU node has generated an error, it notifies two diagnostic information messages; one corresponding to the error of the power supply module on the CPU node and the other corresponding to the error of the power supply module on node 1.

ESB bus and ESB bus interface module

The ESB bus is redundant. The two ESB buses are connected to their corresponding ESB bus interface modules. The following operations also apply when optical ESB bus repeater devices are present along the communication route.

- Normally, redundant ESB buses are used in an alternating fashion.
- If an error occurs in either ESB bus interface module, the user is notified of the error with a diagnostic information message. If both buses fail, the error is treated as a node failure.

- If an error occurs in one ESB bus or ESB bus interface module, the SCS continues communication by using only the other ESB bus that is normal.
- An erroneous bus is monitored for normal recovery at regular intervals.
- Errors in communication with all I/O nodes, except CPU node, are judged to be ESB bus error.

N-ESB bus and N-ESB bus module

The ESB bus has redundant configuration. Each N-ESB bus module is connected to N-ESB bus, respectively.

- Normally, redundant N-ESB buses are used in an alternating fashion.
- If an error occurs on either N-ESB bus module, the error is notified to the user via a diagnostic information message. If both buses fail, the error is treated as a node failure.
- If an error occurs in either N-ESB bus or N-ESB bus module, the SCS continues communication using only the normal ESB bus on the other side.
- An erroneous N-ESB bus is monitored for normal recovery at regular intervals.

F-SB bus

The F-SB bus has redundant configuration.

- The F-SB bus is normally used at the same time on both sides.
- If an error occurs in either F-SB bus, the SCS continues communication using only the normal ESB bus on the other side.
- An erroneous F-SB bus is monitored for normal recovery at regular intervals.

Vnet/IP communication

Vnet/IP is redundant. Independent subnets using bus 1 and bus 2 comprise redundant buses.

Normally, bus 1 is used for control communication. If a communication error occurs on bus 1, bus 2 is used to perform control communication.

A8.6.2 CPU redundant status

The availability of an SCS can be improved by making CPUs redundant. Each of the redundant CPUs can be in either control or standby states, which are unique to the CPU.

CPU status

In order to show the status of a redundant configuration, it is necessary to indicate the status of each CPU separately. The operating status of the CPU is called the CPU status.

- The CPU status indicates the operating status of the CPU.
- The processing of the SCS references the CPU status as necessary. The user can check the CPU status via the CPU's LED, the SCS State Management window of the SENG, and the Status Display view of HIS.
- If an error occurs in the standby CPU, the FAIL status is notified to the application logic via a system block.

The figure below illustrates the CPU status shift. Note that in order to explain the CPU status, the operating modes it can shift to the Initial mode are called "CTRL" and "STBY." These indicate whether the CPU has the control right and are specific to the redundant status, i.e., not related to the operating mode.

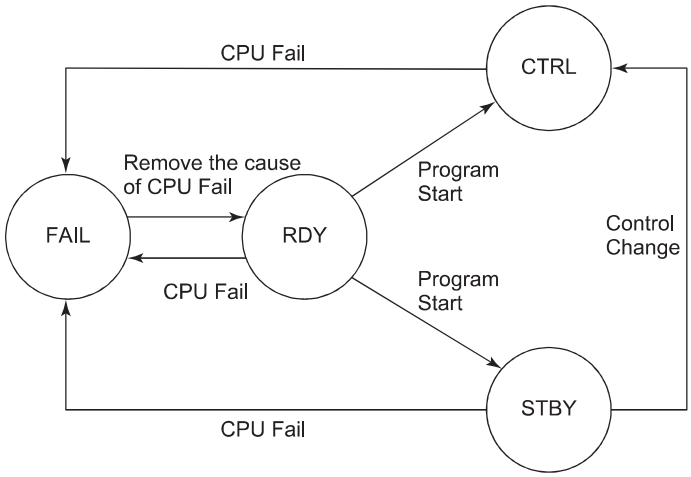

Figure A8.6.2-1 CPU status

FAIL (CPU stopped)

The power is supplied to the CPU, but the software is not running in this status.

RDY (CPU initializing status)

The system program is being set in the main memory in this status.

CTRL (control status)

The system program runs inside the CPU and the CPU has the right to access input/output modules in this status.

STBY (standby status)

The system program runs inside the CPU but the CPU does not have the right to access input/output modules in this status.

CPU status shift in redundant configuration

The figure below illustrates each CPU status and how it may shift in redundant configuration. The thick arrows from (a) to (d) indicate the flow from the startup to normal operation in redundant configuration. Note that the figure below does not represent the status by the mounting positions of the CPUs. Even if the states of the two CPUs are switched, the indication in the figure shows them in the same status.

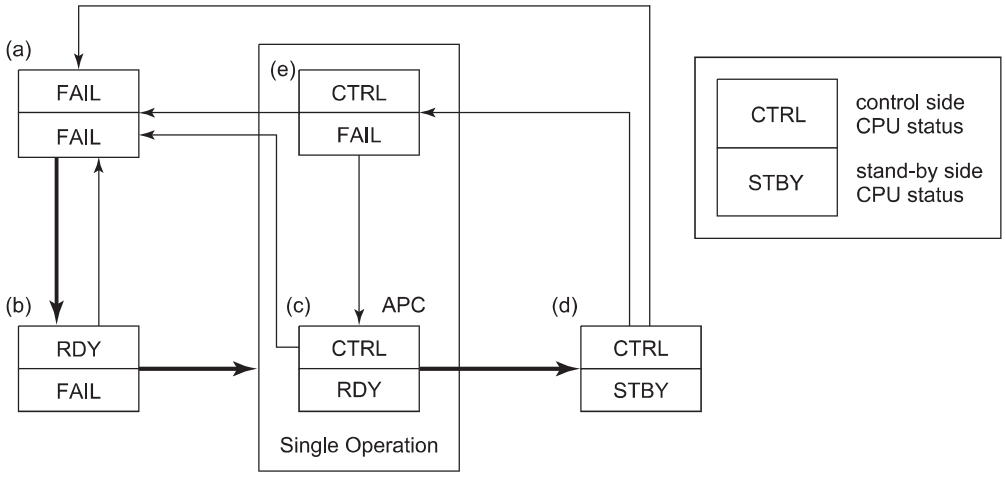

Figure A8.6.2-2 States at redundant configuration

Table A8.6.2-1 CPU status

Status	Description
(a)	CPUs on the both sides stopped.
(b)	The controlling CPU starts up and sets programs and databases in the main memory.
(c) (*1)	The controlling CPU obtains the control right and starts up the standby CPU. Upon launching, the standby CPU copies the image of the main memory of the controlling CPU into its main memory (this status is displayed as "APC" and not the same as status (e)). The controlling CPU executes the user application.
(d)	Both the controlling and standby CPUs operate normally in redundant configuration. This status is called the redundant control status.
(e) (*1)	In this status, the standby CPU is stopped in redundant configuration, or the controlling CPU is stopped and the control right is switched. The same operation as in single configuration is performed.

*1: Single operating status.

The CPU shifts to each status in the following manner.

Table A8.6.2-2 Conditions of CPU status shift

Before	After	Shifting conditions
(a)	(b)	• The power supply to the SCS is started. • SCS offline download is completed. • The system is restarted.
(b)	(c)	The controlling CPU started normally.
(c)	(d)	APC of the standby CPU is completed.
(d)	(e)	The control right is switched due to a failure of the controlling CPU hardware or the standby CPU failed.
(e)	(c)	The standby CPU is replaced or a CPU recovered from transient failure.
(b)	(a)	An error occurred in the self-diagnosis at startup.

Continues on the next page

Table A8.6.2-2 Conditions of CPU status shift (Table continued)

Before	After	Shifting conditions
(c)	(a)	A fatal error occurred while operating in single CPU operation.
(d)	(a)	Power failure occurred in the SCS (including momentary power failure).
(e)	(a)	A fatal error occurred while operating in single CPU operation.

APC status

The APC status refers to the status where the data in the CPU memory is being copied from the control side to the standby side.

The APC status can be checked by the LED on the CPU, the SCS Status Display window of the SENG or the Status Display view on the HIS. The start and end of the APC status are notified via a diagnostic information message.

A8.7 NIU status and security

The N-ESB bus module (S2EN501) that is installed in the node interface unit (NIU) is equipped with a maintenance port.

For the security reason, you should disable the maintenance port when operating the system.

The status of the NIU is determined by the status of the NIU maintenance port and operating mode of the NIU. This section describes the status of the NIU maintenance port, NIU operating mode, and shifting of the NIU status.

Overview of the NIU status and tools

The status of the NIU is determined by the status of the NIU maintenance port and operating mode.

- Status of the NIU Maintenance Port
  The status of the NIU maintenance port can be either enabled or disabled. The status of the maintenance port can be switched between enabled and disabled by using the NIU maintenance port settings tool that is called from the SCS State Management window in the SCS Maintenance Support Tool.
- Operation mode of the NIU
  The NIU operation mode can be either online mode or maintenance mode. The operation mode can be switched between online mode and maintenance mode by using the N-IO maintenance tool in the computer that is connected to the maintenance port.

  The N-IO maintenance tool can be used if the NIU maintenance port is enabled.

IMPORTANT

The Node number setting tool and FieldMate Validator are included in the N-IO maintenance tool.

A8.7.1 Status of the NIU maintenance port

You can run the NIU maintenance port settings tool and enable or disable access from an external device such as a computer connected to the maintenance port of the N-ESB bus module.

Disabled status

The disabled status of the maintenance port prohibits access from the maintenance port.

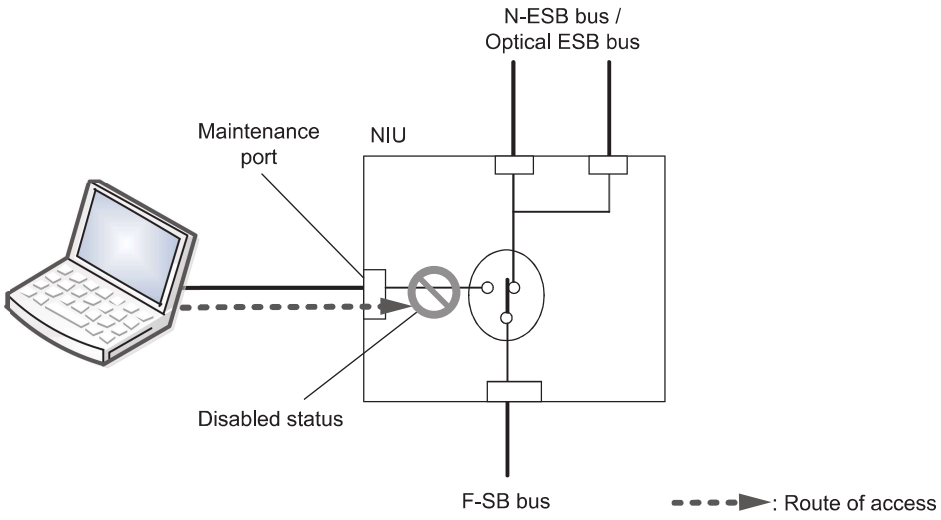

Figure A8.7.1-1 Disabled status of the maintenance port

Enabled status

The enabled status of the maintenance port allows access from the maintenance port.

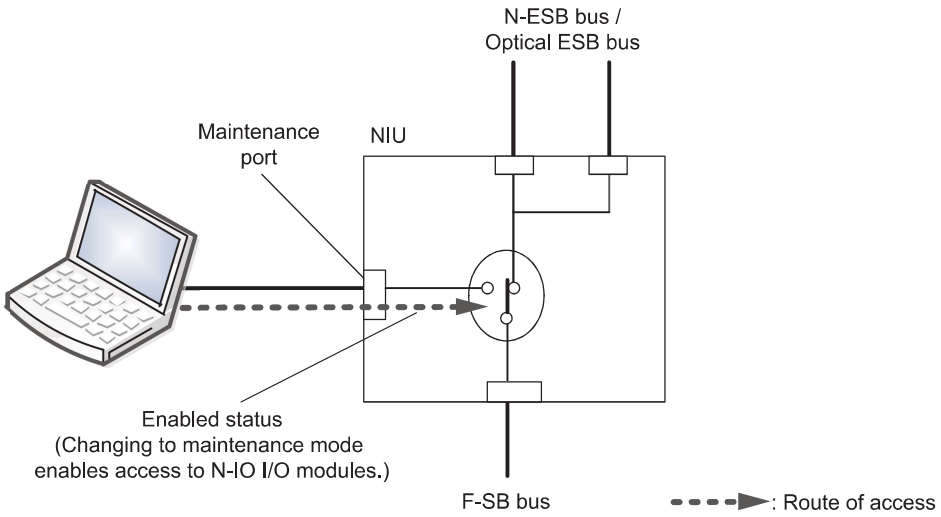

Figure A8.7.1-2 Enabled status of the maintenance port

SEE ALSO For more information about how to enable/disable the maintenance port, refer to:

I4.5, “NIU maintenance port setting tool” on page I4-77

A8.7.2 Operation mode of the NIU

The NIU operation mode can be either online mode or maintenance mode.

Online mode

In online mode, you can access the N-IO I/O modules from the N-ESB bus or the optical ESB bus.

You cannot access the N-IO I/O modules from the maintenance port.

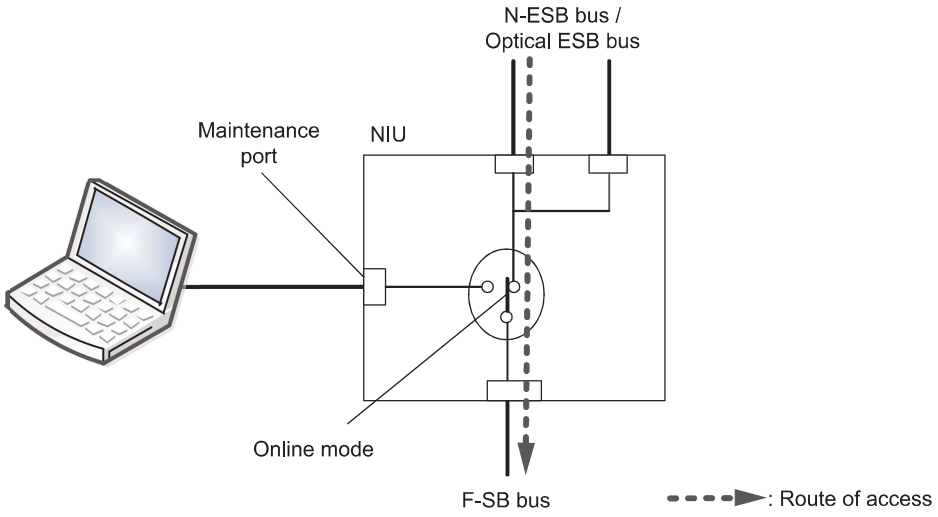

Figure A8.7.2-1 Online mode

Maintenance mode

In maintenance mode, you can access the N-IO I/O modules from the maintenance port.

You cannot access the N-IO I/O modules from the N-ESB bus or the optical ESB bus.

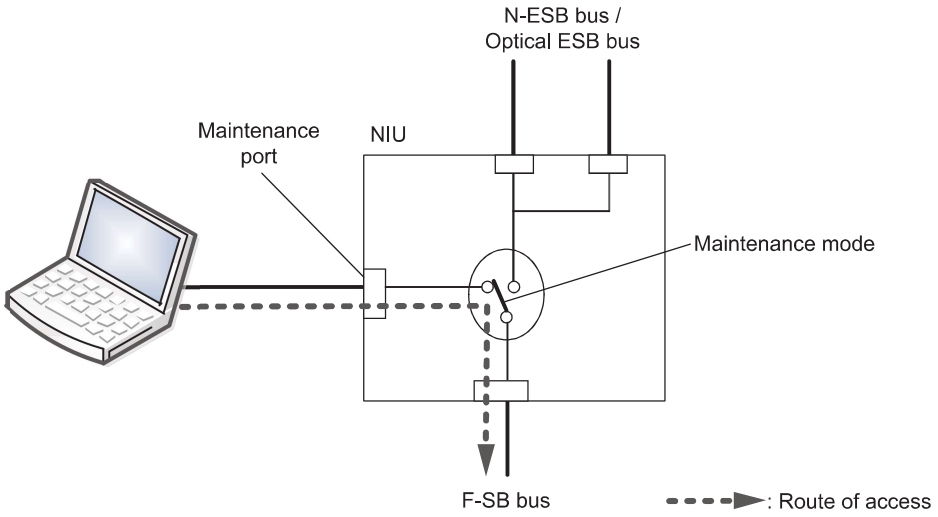

Figure A8.7.2-2 Maintenance mode

Switching between operation modes

This section describes how to switch between the NIU operation modes.

- Switching from the online mode to the maintenance mode

When the maintenance port is enabled, perform the "maintenance instructions" operation from the N-IO maintenance tool connected to the maintenance port to switch from the online mode to the maintenance mode.

- Switching from the maintenance mode to the online mode.
  Perform on of the following to switching from the maintenance mode to the online mode.
  - Perform the "release maintenance instructions" operation from the N-IO maintenance tool connected to the maintenance port.
  - Disconnect the USB cable that is connected to the maintenance port
  - Turn off the power of the NIU, then turn it on

IMPORTANT

When the node number setting tool is used as a N-IO maintenance tool, the unit will switch to the maintenance mode when a node address is configured. After the node address is configured, the unit will switch to the online mode.

TIP

- Switching the maintenance mode of the dual-redundant N-ESB bus modules
  Because the N-ESB bus modules are dual-redundant, when you change the operation mode on one side, the operation mode of the other side will switch accordingly.

SEE ALSO

For more information about Node Number Setting Tool, refer to:

F2.1.1, “Using the Node Number Setting Tool” on page F2-3

For more information about FieldMate Validator, refer to:

Manual of FieldMate Validator

A8.7.3 Shifting the Status of the NIU

The following figure shows the status and the operation mode of the NIU maintenance port, and the status shift with regards to external access.

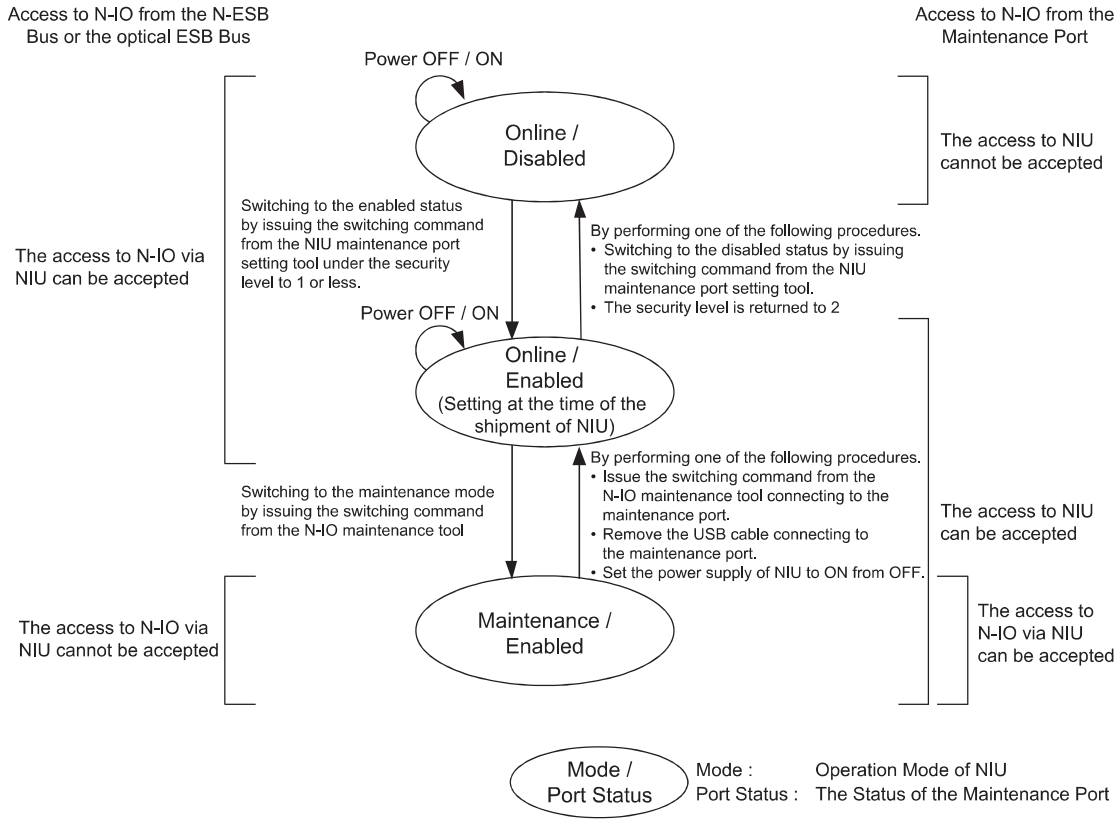

Figure A8.7.3-1 NIU status shift

The following table shows the factory settings of the N-ESB bus modules (S2EN501) that are installed in the NIU.

Table A8.7.3-1 NIU factory settings

Target	Setting	Status
Operation mode	Online mode	The CPU module accesses the N-IO modules from the N-ESB bus and optical ESB bus through the NIU.
Status of the maintenance port	Enable	You can access the NIU from the N-IO maintenance tool.
Node number	Not set	The NIU is not operating correctly. You need to set the node number before connecting to the SCU.

A9. Capacity of SCS applications

This section describes the application capacity related to the SCS.

Table A9-1 Capacity of SCS applications

Types	Items	SCSP3 Max. capacity		SCSL2 Max. capacity	SCSP2 Max. capacity	SCSV1, SCSP1, SCSU1 Max. capacity	Note
		When using N-IO	When using FIO				
I/O	Number of nodes	32	13	13	13	9	CPU node is not included in the number of nodes.
	Number of units	6	-	-	-	-	Maximum 108 units per SCS
	Number of slots	2	8	8	8	8	When connecting I/O node, the maximum slot number of CPU nodes is 6.
	Number of I/O modules	108 non-redundant modules, or 108 pairs of redundant modules	110	110	110	110	The total number of FIO and N-IO I/O modules can be up to 110. However, the total can only be up to 109 when the total number of ESB bus coupler modules and N-ESB bus coupler modules is 4 sets. The number of I/O modules is the number of sets in a redundant configuration and the number of modules in a single configuration. Communication modules are included in the number of FIO I/O modules.
	Number of communication modules	2		2	2	2	For Modbus Slave Communication
		-		-	-	2	For communication as a DNP3 slave (SCSU1 only)
		4		4	4	4	For Subsystem Communication
		8		-	-	-	For safety subsystem communication
	Number of I/O points	1500 (1500 in redundant I/O modules)	1500 (800 in redundant I/O modules)	1500 (800 in redundant I/O modules)	1500 (800 in redundant I/O modules)	1000 (500 in redundant I/O modules)	The numbers are provided only as a guide.
	Number of Subsystem Communication Data	2000 data		2000 data	2000 data	500 data (SCSV1) 2000 data (SCSP1, SCSU1)	Per SCS

Continues on the next page

Table A9-1 Capacity of SCS applications (Table continued)

Types	Items	SCSP3 Max. capacity		SCSL2 Max. capacity	SCSP2 Max. capacity	SCSV1, SCSP1, SCSU1 Max. capacity	Note
		When using N-IO	When using FIO				
I/O	Number of safety subsystem communication data	2000 data		-	-	-	Per SCS The safety subsystem communication I/O area is 4000 words and the minimum unit of data that can be assigned to this area is 2 words. For this reason the maximum number of data is 2000 data. The maximum number of data when only GS01 is connected is approximately 1350 data. (*1)
Application logic	Number of programs and user-defined FU/FB (number of POUs)	Max. 500		Max. 500	Max. 500	Max. 500	When more than 500 POUs are defined, a build error occurs. It may not be possible to define 500 POUs depending on the type and number of FU/FB or LD elements. A restriction may be imposed depending on SCS performance.
	Definable number of variables	1500 I/O variables. 4500 internal variables		1500 I/O variables. 4500 internal variables	1500 I/O variables. 4500 internal variables	1000 I/O variables. 3000 internal variables.	The numbers are provided only as a guide. It may not be possible to define the maximum number of variables shown in the left columns depending on each type of defined variables and the performance of SCS.
Inter-SCS Safety Communication	Send data	200 data		200 data	200 data	200 data	This is the maximum number of send data per SCS.
	Receive data	200 data		200 data	200 data	200 data	This is the maximum number of receive data per SCS.
SCS Link Transmission	Send data	128 data		128 data	128 data	128 data	This is the maximum number of send data per SCS.
	Receive data	1000 data		1000 data	1000 data	1000 data	This is the maximum number of receive data per SCS.

Continues on the next page

Table A9-1 Capacity of SCS applications (Table continued)

Types	Items	SCSP3 Max. capacity		SCSL2 Max. capacity	SCSP2 Max. capacity	SCSV1, SCSP1, SCSU1 Max. capacity	Note
		When using N-IO	When using FIO				
CENTUM integration function and CI Server integration function (*2)	Annunciators (%AN)	2000		2000	2000	1000	-
	Common switches (%SW)	800		800	300	200	All are system switches.
	External Communication FB	(*3)		(*3)	(*3)	(*3) (*4)	-
	External communication FB (with data retaining function)	-		-	-	(*4)	SCSU1 only. The maximum capacity is limited by the size of the area for data retention.
Gas flow rate calculation function	Gas flow rate calculation FB (Total of AGA_*)	-		-	-	1	SCSU1 only
	Report data creation FB (AGA_R)	-		-	-	1	SCSU1 only
Mapping block	Analog input blocks (ANLG_S, ANLGI, HSDTR, GASDTR)	Total 2700		Total 2700	Total 2700 (*5)	Total 1800 (*5) (*6)	-
	Velocity alarm blocks (VEL)						-
	Maintenance override blocks (OVR_*, GOV_*)						OVR_B, OVR_I, OVR_R, OVR_IB, OVR_IR, GOV_B, GOV_IB
	Password blocks (PASSWD)						-
	Manual operation blocks (MOB_*, MOA)						MOB_11, MOB_21, MOB_RS, MOA
	Gas flow rate calculation blocks (AGA_3, AGA_7, AGA_R)	-		-	-		-
	Annunciator blocks (ANN, ANN_FUP)	2000		2000	2000	1000	Mapping to %AN element

Continues on the next page

Table A9-1 Capacity of SCS applications (Table continued)

Types	Items	SCSP3 Max. capacity		SCSL2 Max. capacity	SCSP2 Max. capacity	SCSV1, SCSP1, SCSU1 Max. capacity	Note
		When using N-IO	When using FIO				
Communication I/O area	Overall size of %W	4000 Words		4000 Words	4000 Words	4000 Words	1 Word = 16 Bits
	%W: For mapping (BOOL)	200 Words (3200 Bits)		200 Words (3200 Bits)	200 Words (3200 Bits)	200 Words (3200 Bits)	1 data = 2 words, 100 data
	%W: For mapping (32-bit analog data)	1800 Words		1800 Words	1800 Words	1800 Words	900 data
	%W: For subsystem communication	1000 Words		1000 Words	1000 Words	1000 Words	Up to 2000 data in total of bit data and analog data can be assigned.
	%W: Not used	1000 Words		1000 Words	1000 Words	1000 Words	
Safety subsystem communication I/O area	%X: For safety subsystem communication	4000 Words		-	-	-	1 Word = 16 Bits The minimum unit of data that can be assigned to the safety subsystem communication I/O area is 2 words. For this reason the maximum number of data is 2000 data.
Modbus Slave	Coil	1000 Bits		1000 Bits	1000 Bits	1000 Bits	-
	Input relay	4000 Bits		4000 Bits	4000 Bits	4000 Bits	-
	Input register	4000 Words		4000 Words	4000 Words	4000 Words	1 word = 16 bits, 1 data = 2 words, 2000 data
	Holding register	1000 Words		1000 Words	1000 Words	1000 Words	500 data
SOE	Event	15000 events		15000 events	15000 events	15000 events	Saved in the SOE storage area (RAM)
		Last 1000 events		Last 1000 events	Last 1000 events	Last 1000 events	Saved in the NVRAM (nonvolatile RAM)
	Trip signal file	2 trip signal files of up to 1500 events		2 trip signal files of up to 1500 events	2 trip signal files of up to 1500 events	2 trip signal files of up to 1500 events	Saved in the NVRAM (nonvolatile RAM)
Diagnostic information message	Diagnostic information message	5000 messages		5000 messages	5000 messages	5000 messages	Saved in the area for saving diagnostic information messages (RAM)
		Last 200 messages		Last 200 messages	Last 200 messages	Last 200 messages	Saved in the NVRAM (nonvolatile RAM)
Data buffering	Number of buffers	-		-	-	135000	SCSU1 only
Area for data retention	Size of area for data retention	-		-	-	6 Kbyte	SCSU1 only

*1: Example of when 3 definitions (1 definition of data used with safety communication where the number of data is 2 with 8 words, 2 definitions of data used with an interference-free function where the number of data is 1 with 2 words) are used with

a single GS01. The formula is: (4000 words / 12 words) x 4 data = approximately 1350 data. In this case, the number of GS01 units connected is approximately 300 units (4000 words / 12 words).

*2: The CENTUM integration function can be used with SCS of types SCSP3, SCSL2, SCSP2, SCSP1, and SCSV1. The CI Server integration function can be used with SCS of types SCSP3, SCSP2, SCSP1, and SCSU1.

*3: For SCS other than SCSU1, the maximum capacity can be defined as follows:
- When using Modbus, the maximum definable number of external communication FB is up to 1000 for ECW_B and 500 for ECW_I and ECW_R in combination.
- In tag assignment, up to 3200 Boolean internal variables and ECW_B FB in combination can be defined.
- In tag assignment, up to 900 DINT and REAL internal variables, input variables of IO_REAL and FB of ECW_I and ECW_R in combination can be defined.

*4: For SCSU1, the maximum capacity can be defined as follows:
- When using Modbus, ECW_B and ECWR_B can be defined up to 1000 in total. ECW_I, ECWR_I, ECW_R, and ECWR_R can be defined up to 500 in total.
- Up to 3200 tag names can be defined in total for Boolean internal variables and function blocks of ECW_B and ECWR_B.
- Up to 900 tag names can be defined in total for DINT and REAL internal variables, input variables of IO_REAL, and function blocks of ECW_I, ECWR_I, ECW_R, and ECWR_R.

*5: In CI Server integration, HSDTR, GASDTR, OVR_*, GOV_*, PASSWD, MOB_*, and MOA cannot be used.

*6: For SCSU1, this is the total including AGA_3 or AGA_7 and AGA_R.

A10. Outline of the safety system generation function

This section gives an overview of the tools used to configure and maintain a safety system.
It also describes the different types of applications that can be created by using ProSafe-RS.

A10.1 Engineering method by using the safety system generation function

You can perform ProSafe-RS engineering by using SCS Manager and AD Suite. AD Suite can be largely separated into AD Server, which manages project data, and AD Organizer, which is an engineering tool. Project data is registered and managed in AD Server.

SEE ALSO For more information about AD Suite, refer to:

A., “Overview of Automation Design Suite” in Engineer's Reference Manual (IM 32P04B10-01EN)

Guidelines for selecting an engineering method

There are two engineering methods for ProSafe-RS: I/O list engineering and RS original engineering. They are each defined as follows:

- I/O list engineering
  The safety I/O list is loaded to AD Organizer and the data is engineered by using the I/O List Engineering Package.

  When using iDefine and when performing engineering for safety subsystem communication, select I/O list engineering.

- RS original engineering
  This method is performed without using the I/O List Engineering Package. The engineering tools of SCS Manager are used.

  If RS projects, including SCS projects, are registered in AD Server, the history management function of AD Suite can be used.

Select the appropriate engineering method depending on whether you are using the I/O List Engineering Package. The engineering method can only be selected when creating a new SCS project. You cannot change the engineering method later.

TIP If you upgrade to version R4, the metered license is applied regardless of the engineering method that you select.

SEE ALSO For more information about SCS project and RS project, refer to:

C1.1, “Type of project” on page C1-2

Precautions when using RS projects that were created before introducing AD Suite

In AD Server, we recommend that you register SCS projects that were created before introducing AD Suite. In this user’s manual, descriptions about RS original engineering are explained with the assumption that RS projects have been registered to AD Server. If you use SCS projects that have not been registered in AD Server, you will not be able to use the AD Suite functions described in this user’s manual.

A10.2 SCS Manager

You can call SCS Manager from AD Organizer. You can create a new SCS project by using SCS Manager and call the SCS engineering and maintenance tools.

From the [Tools] menu of SCS Manager, three launchers can be started.

From each launcher, various engineering functions such as builders, SCS related tools and SCS Maintenance Support Tool can be launched. This section mainly explains the precautions when closing and opening SCS projects and launchers started from SCS Manager.

Precautions when opening SCS projects

IMPORTANT

SCS projects cannot be opened if you cancelled password input (except when read-only access is permitted without entering a password) or failed to enter the correct password three times while attempting to open SCS projects for which passwords are set. Close SCS Manager and try opening it again.

Projects that have not been created as databases to be edited in SCS Manager of ProSafe-RS cannot be opened.

It is not possible to open the same SCS project in SCS Manager, Version Control Tool and Master Database Restoring Function at the same time.

Precautions when closing SCS projects

This section describes the precautions when closing SCS Manager.

- Closing SCS Manager closes the currently opened SCS project.
- When you close SCS Manager, all the related builders, Safety Analyzer and launchers close. If the security level is not Level 2 when closing, a message prompting the user to return to Level 2 appears. Set the SCS's security level to Level 2 by using the SCS Security Level Management Function.
- SCS Maintenance Support Tool is not closed even if SCS Manager is closed.

TIP

The SCS project opened in SCS Manager cannot be opened in Version Control Tool or Master Database Restoring Function. To use these tools, close SCS Manager.

SEE ALSO

For more information about how to operate the SCS security level operation function, refer to:

B3., "Security of SCS" in ProSafe-RS User's Guide (IM 32P01B10-01EN)

Starting and closing launchers

From the [Tools] menu of SCS Manager, the following three launchers can be started.

- [Engineering]
  Starts the Engineering launcher such as builders.
- [Controller]
  Starts the SCS launcher.
- [Maintenance]
  Starts the Maintenance launcher.

TIP The menu items for starting launchers are also displayed in the pop-up menu opened by right-clicking when a configuration and/or resource are selected in SCS Manager or Dictionary View is opened.

Starting launchers

Each launcher is started from the [Tools] menu. If the same launcher has already been started, a new launcher is not started; instead, the already started launcher is displayed on the foreground and given the focus.

The Engineering launcher and the Maintenance launcher have a push-pin icon. If you place the push-pin icon in the pressed status, the corresponding launcher is always displayed on the foreground without being hidden by other windows. If you disable the push-pin icon, the launcher may be hidden by other windows.

The Controller launcher is always displayed on the foreground.

If two or more launchers are set to be displayed on the foreground, the launcher started up later is displayed on the foreground.

Closing launchers

Each launcher is closed if you click "Close" button of the launcher or close SCS Manager. If you close a launcher by clicking "Close" button, only the launcher is closed and windows opened from the launcher are not closed.
The Controller launcher closes if a menu is selected and the corresponding tool is started.

Engineering launcher

The table below shows builders and tools that can be started from the Engineering launcher.

Table A10.2-1 Engineering launcher menu

Menu item	Operation
SCS Project Properties	Opens the SCS Project Properties dialog box
SCS Constants Builder	Starts SCS Constants Builder
I/O Parameter Builder	Starts I/O Parameter Builder
Communication I/O Builder	Starts Communication I/O Builder
SCS Link Transmission Builder	Starts SCS Link Transmission Builder
Modbus Address Builder	Starts Modbus Address Builder
DNP3 Communication Builder (*1)	Starts DNP3 Communication Builder
Tag Name Builder (*2)	Starts Tag Name Builder
Alarm Priority Builder (*2)	Starts Alarm Priority Builder
Alarm Processing Table Builder (*2)	Starts Alarm Processing Table Builder
Integrity Analyzer	Starts Integrity Analyzer
Cross Reference Analyzer	Starts Cross Reference Analyzer
Database Validity Check	Starts Database Validity Check Tool
SCS Information	Opens the SCS Information dialog box

*1: DNP3 Communication Builder is displayed only for the SCS projects of SCSU1 that are created by the software version R3.02.20 or later.
*2: Only opened in the case of CENTUM integration structures.

If a library project is open in SCS Manager, only the [SCS Project Properties] and [Integrity Analyzer] menu items are displayed.

Controller launcher

The table below shows tools that can be started from the Controller launcher.

Table A10.2-2 Controller Launcher Menu

Menu item		Operation
Save Operation Marks (*1)		Save the operation marks set on CENTUM HIS to SENG
Download Operation Marks (*1)		Download the saved operation marks to SCS
Reset SCS	Restart SCS	Restarts an SCS
	Master Database Offline Download	Performs master database offline download

*1: Only opened in the case of CENTUM integration structures.

If a library project is open in SCS Manager, the Controller launcher cannot be started.

Maintenance launcher

The table below shows tools that can be started from the Maintenance launcher.

Table A10.2-3 Maintenance launcher menu

Menu item	Operation
SCS Status Overview	Starts the SCS Status Overview of SCS Maintenance Support Tool
SCS State Management	Starts the SCS State Management of SCS Maintenance Support Tool
Set SCS Security Level	Opens the Set SCS Security Level dialog box.
I/O Lock Window	Starts the I/O Lock Window
Communication I/O Lock Window	Starts the Communication I/O Lock Window
SCS Link Transmission Lock Window	Starts SCS Link Transmission Lock Window
Inter-SCS Communication Lock Window	Starts Inter-SCS Communication Lock Window
SCS Test Function (*1)	Starts SCS Test Function
Update SCS Test Database (*1)	Updates SCS Test Database

*1: In the case of CENTUM integration structures, this menu item is displayed when the SCS project is a default project or a user-defined project.

If a library project is open in SCS Manager, the Maintenance launcher cannot be started.

IMPORTANT

If SCS Manager is in the logic simulation mode, the I/O Lock window, Communication I/O Lock window, SCS Link Transmission Lock window, and Inter-SCS Communication Lock window cannot be started.

Show/hide SCS Manager toolbars

If you launch SCS Manager or Multi-Language Editor, the displayed toolbar will be the same as that before, when you closed last time. The toolbar display is retained per each Safety Engineering PC (SENG) and cannot be set per each user. If you hid the toolbar last time you used the SCS Manager or Multi-Language Editor and if you want the toolbar to show this time, for example, change the show/hide status of the toolbar.

Follow the steps below to show or hide the toolbar.

1. On the [Options] menu, click [Layout].
   The Layout dialog box appears.

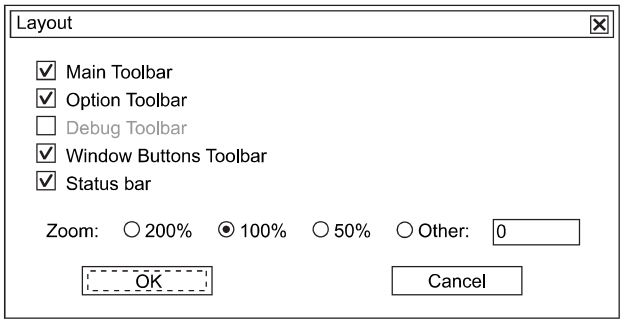

Figure A10.2-1 Layout dialog box

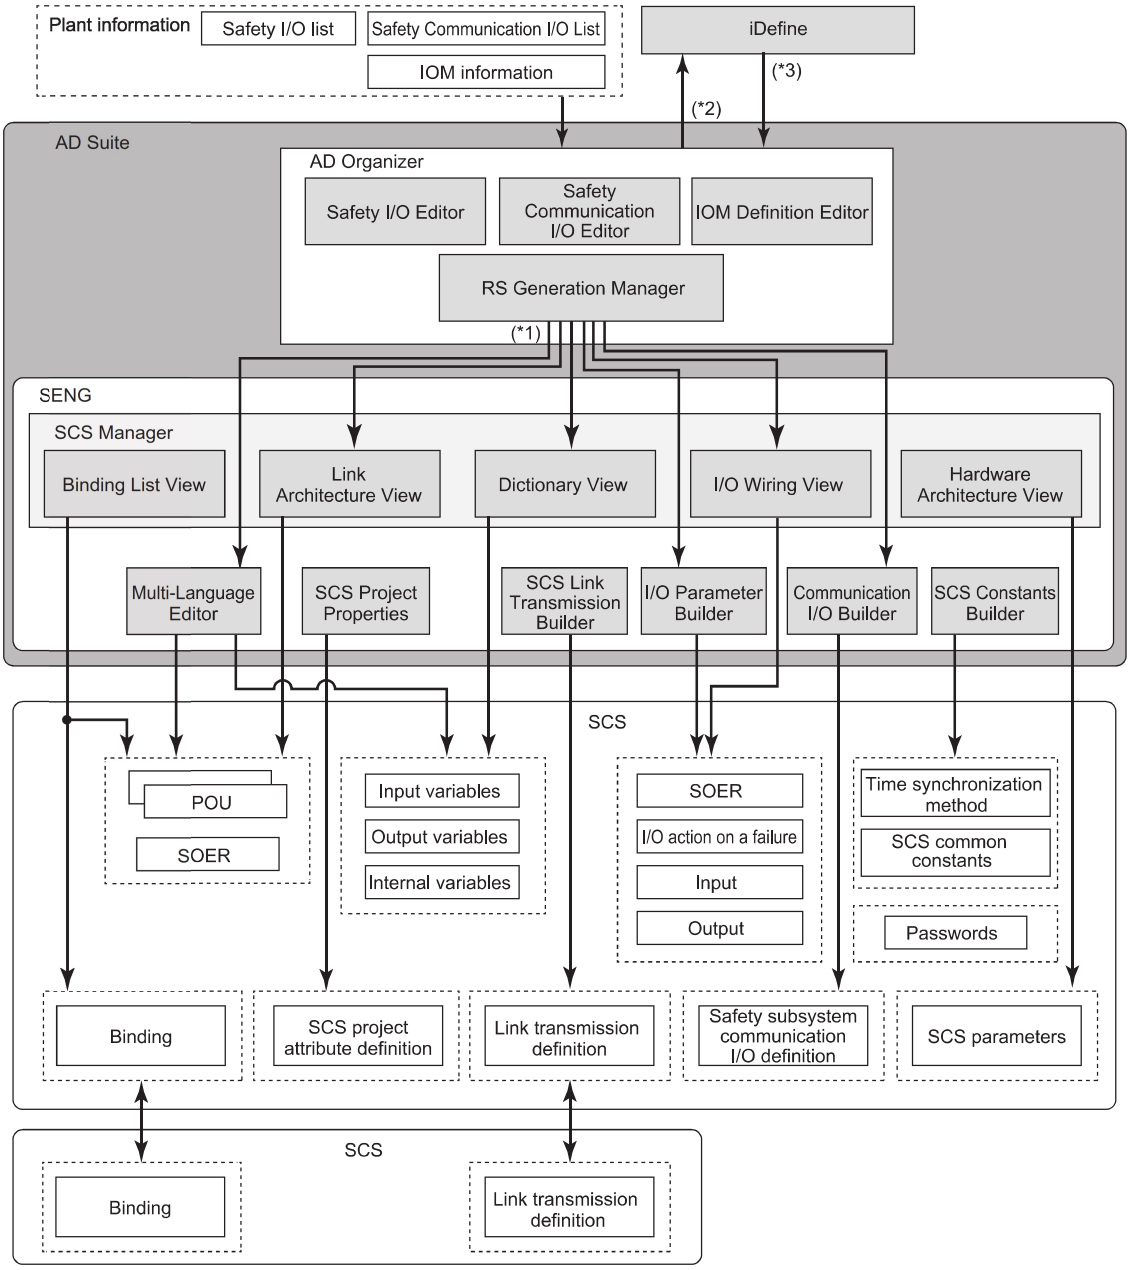

2. Select the check boxes of the toolbar you want to show.
   If you want to hide the toolbar, clear all the check boxes.
3. Click [OK].
   To change the docking or floating status of the toolbar, drag it to the position you like.

A10.3 Safety application definition

Safety applications are created with tools and builders called from the AD Organizer and the SCS Manager.

When using AD Suite to perform I/O list engineering, you need to use the editors in AD Organizer to set the items instead of using I/O Wiring View, I/O Parameter Builder, and Communication I/O Builder.

If you select I/O list engineering and use iDefine, you can create the application logic by using iDefine based on the ProSafe-RS I/O file that was exported from AD Organizer. The ProSafe-RS I/O file is a file generated for engineering with iDefine based on the safety I/O list, safety communication I/O list, and IOM definition.

*1 : In the case of I/O list engineering, you can reflect the safety I/O list, safety communication I/O list, and IOM definition to the SCS Manager builder by running the reflection process through RS Generation Manager. If you run the reflection process on the engineering data that was created by using iDefine through RS Generation Manager, the application data can be reflected to the Multi-Language Editor and SCS.

*2 : AD Organizer exports the data that was created from the safety I/O list, safety communication I/O list, and IOM definition to iDefine.

*3 : AD Organizer imports the engineering data that was created by using iDefine.

Figure A10.3-1 Overview of safety application definition

AD Organizer

AD Organizer is installed in the SENG computer. You can perform the ProSafe-RS engineering by using AD Organizer. AD Organizer comes with some built-in engineering tools, and SCS Manager is one of them.

Safety I/O Editor

This is an engineering tool that can be used from AD Organizer.

The tool is used to create safety I/O lists based on plant information data and import them as engineering data.

It is also used to define variables that are related to the safety I/O. You specify the SCS node and IOM applicable to the P&ID tag and the associated connection information based on the information that is displayed in the Safety I/O Editor.

With this editor, you can export a file containing data for engineering with iDefine.

Safety Communication I/O Editor

This is an engineering tool that can be used from AD Organizer.

This tool is used to create safety communication I/O lists based on plant information data and import them as engineering data.

It is also used to define variables that are related to the safety communication I/O. You specify the SCS node and IOM applicable to the P&ID tag and the associated connection information based on the information that is displayed in Safety Communication I/O Editor.

With this editor, you can export a file containing data for engineering with iDefine.

IOM Definition Editor

This is an engineering tool that can be started from AD Organizer.

In the IOM Definition Editor, a list of nodes and I/O modules are displayed with their properties.

You can use the IOM Definition Editor to define the I/O module configuration and set the properties of nodes and I/O modules. If I/O module assignment information is not defined in the safety I/O list or safety communication I/O list, you can define the assignment of I/O modules to nodes by using IOM Definition Editor.

ADMDB

This is the server database that stores all the engineering data that is included in the AD Server. The revision history of the engineering data and the hardware configuration information are also stored in this database.

The AD Server manages the engineering data.

Generation Manager

For SCS projects that are created with I/O list engineering, Generation Manager reflects the information of the safety I/O lists, safety communication I/O lists, and I/O module configuration and builds SCS projects.

SCS Manager

This is installed in the computer of SENG. It is an environment for creating application logic.

Hardware Architecture View

- Set the configuration name.

- Define the IP address of the SCS.

Link Architecture View

- Configuring the security settings of the SCS project.
- Defining the POU.(*1)
- Adding variable groups.
- Starting the Multi-Language Editor to edit the POU that you have defined.

*1: POU: Program Organization Unit It is a generic term for the programs, function blocks (FB), and functions (FU) that are written with the function block diagram (FBD) and ladder diagram (LD)

SCS Project Properties

Defining Project properties including station type, domain number, and station number of SCS.

Designating location of the integrated CENTUM project folder, in the case of CENTUM Integration Configuration.

SCS Constants Builder

Setting SCS common constants and time synchronization method.

Dictionary View

If you select the RS original engineering method, the Dictionary View is used to set the parameters of FUs and FBs and define project variables. If you select the I/O list engineering method, the variables that were defined by using AD Organizer and iDefine are read-only in Dictionary View.

Multi-Language Editor

Edit the POUs for the LBD, LD, and ST.

POUs that were defined by using iDefine are read-only in Multi-Language Editor.

Binding List View

Binding variables from the producer to the consumer of Inter-SCS safety communication.

SCS Link Transmission Builder

Defining SCS link transmission safety communication and SCS global switch communication.

I/O Wiring View

In the SCS project where the RS original engineering method is selected, the I/O Wiring View is used to define the following:

- Analog I/O module, digital I/O module, universal type I/O module (these three types of modules are collectively called "AIO/DIO modules"), and communication module
- Wiring between I/O module channels and I/O variables

If you select I/O list engineering, this builder is read-only.

I/O Parameter Builder

In the SCS project where the RS original engineering method is selected, I/O Parameter Builder is used to configure the node, module, and channel parameters, including the settings for the operation when a fault is detected in an I/O module or channel, and to define SOER collection through DI/DO.

If you select I/O list engineering, this builder is read-only.

- ### Communication I/O Builder

  For SCS projects for which I/O list engineering is selected, this builder becomes read-only. Use Safety Communication I/O Editor when you assign communication I/O data for safety subsystem communication and perform wiring of communication I/O variables. The contents of Safety Communication I/O Editor will be reflected in this builder by running a reflection from AD Organizer.

iDefine

iDefine is an external engineering tool. Using iDefine, you can create application logic based on data such as the safety I/O list, safety communication I/O list, and IOM information obtained from AD Organizer.

Once data related to the application logic that was created using iDefine is exported to a file and then imported using AD Organizer, the content can be reflected in SCS Manager by using RS Generation Manager.

The safety I/O list, safety communication I/O list, and IOM information created with AD Organizer are read-only in iDefine.

The engineering data that were created in iDefine and reflected in SCS Manager are read-only in SCS Manager.

A10.4 CENTUM integration application definition

The following figure shows the outline of CENTUM integration application definition and the associated builders.

These builders are opened from the engineering launcher of the SCS Manager.

- Tag Name Builder
  This builder defines tag names for FBs and variables which can be used for CENTUM Integration Configuration, and also defines annunciator messages.

  Defining a tag name results in the creation of a mapping block for CENTUM Integration Configuration.

  When engineering by using iDefine, you can also define the tag names for FBs and variables by using iDefine. Use the reflection process from Generation Manager to reflect the definitions in Tag Name Builder. Tag names that were defined by iDefine are read-only in Tag Name Builder.
- Alarm Priority Builder
  This builder defines alarm priority. The condition of alarm activation is set to each alarm priority as in CENTUM.
- Alarm Processing Table Builder
  The Alarm Processing Table Builder is used to import the ‘Alarm Processing Table defined in CENTUM’ to SCS project.

  This table determines the priority of process alarms that are generated from mapping blocks when integrating with CENTUM.

When engineering by using iDefine, you can also configure the tag names in iDefine. The tag names are read-only except for configured tools.

In a CENTUM integration structure, the application of ProSafe-RS needs to be defined with those builders. Furthermore, engineering of CENTUM including SCS definition and tag list generation needs to be executed on CENTUM ENG. This allows HIS to access SCS data with a tag name and to display annunciator messages.

The following figure provides an overview of CENTUM Integration Application Definition.

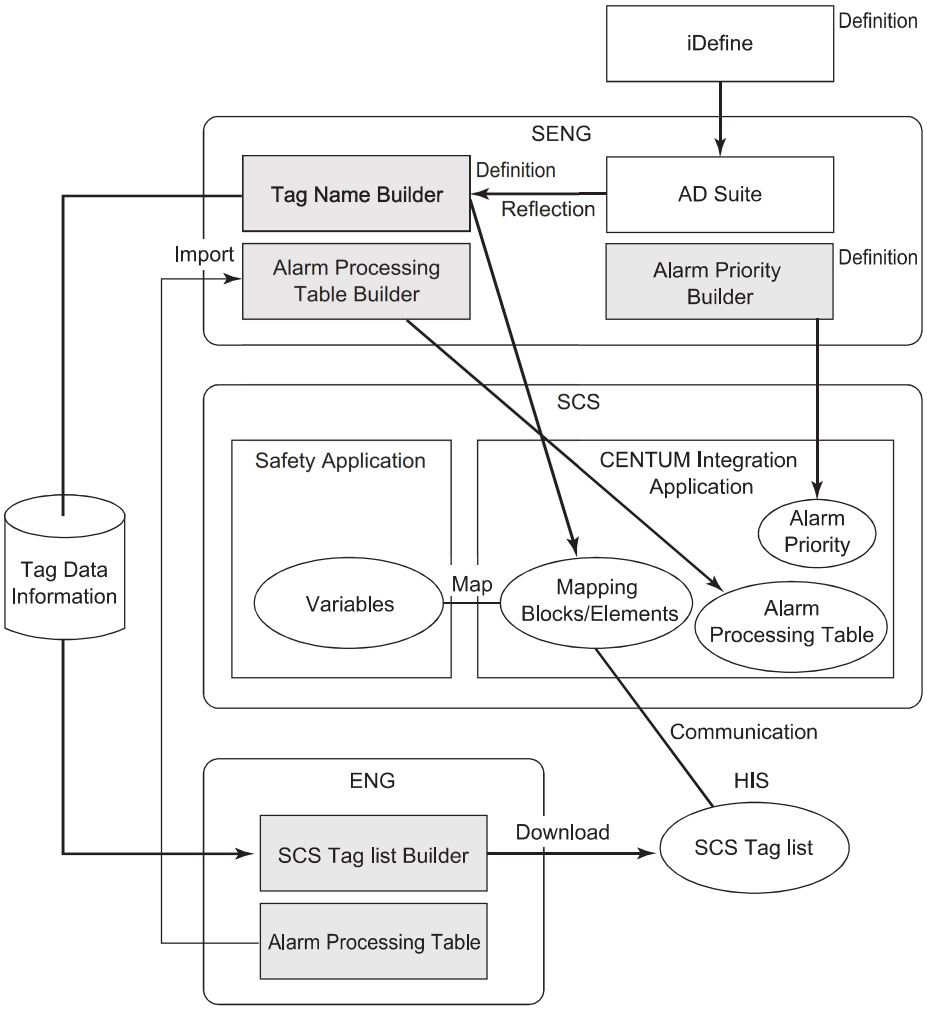

Figure A10.4-1 Outline of CENTUM Integration Application Definition

A10.5 Defining applications that use communication modules

In ProSafe-RS, you can create an application that exchanges data with other system through a communication module. Modbus slave communication, Modbus subsystem communication, and safety subsystem communication are supported. Safety subsystem communication can be used with SCSP3 only. In addition, you can create DNP3 communication applications in SCSU1. Modbus slave communication and Modbus subsystem communication are interference-free functions. Safety communication is included in safety subsystem communication.

The following builder is used for Modbus slave communication:

- Modbus Address Builder
  It defines the Modbus device address.

The following figure shows the outline of the definitions of Modbus slave communication application.

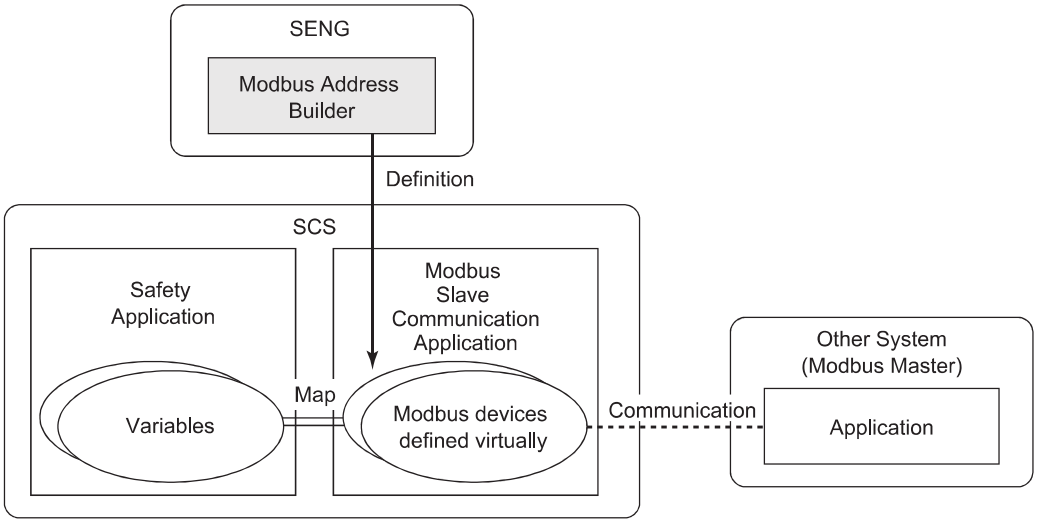

Figure A10.5-1 Outline of Modbus slave communication application definition

The following builder or editor is used for subsystem communication:

- Communication I/O Builder (for RS original engineering)
- Safety Communication I/O Editor of AD Organizer (for I/O list engineering)
  It defines the communication data, and allocates the communication I/O FB there.

The following two types of subsystem communication are supported:

- Using the serial communication module, you can create an application for subsystem communication between SCS and Modbus PLC. By creating an application for subsystem communication between SCS and ProSafe-SLS, you can acquire events and data of ProSafe-SLS.
- Using Ethernet communication module, you can create an application for the subsystem communication between the SCS and Modbus/TCP PLC.

The following editor is used for fire and gas communication:

- Safety Communication I/O Editor of AD Organizer
  Define communication data and assign the PROFINET communication I/O FB and fire and gas communication FB to the communication data.

  Using fire and gas communication modules, you can create an application for safety subsystem communication between the SCS and fire and gas devices.

The following builder is used to define DNP3 communication applications:

- DNP3 Communication Builder
  This builder enables SCS to act as a DNP3 slave station and associates DNP3 data with application logic variables.

The following figure shows the outline of the DNP3 communication application definitions.

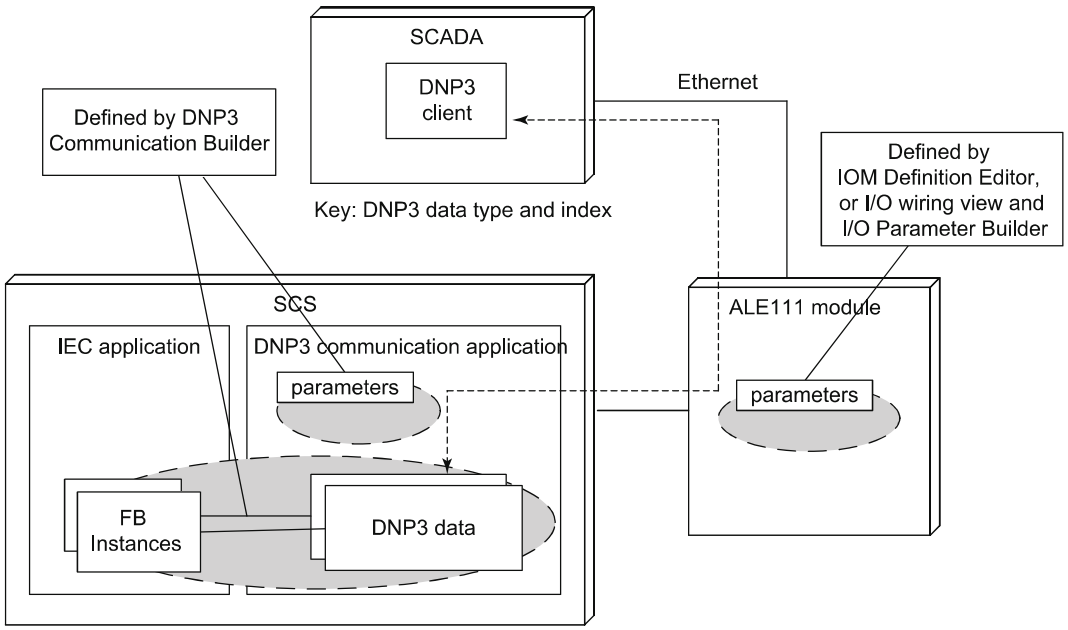

Figure A10.5-2 Outline of DNP3 communication application definition

A10.6 CI Server integration application definition

The following describes the builder and outline of the CI Server integration application definitions. CI Server integration is an interference-free function.

In CI Server integration, you can define I/O modules and create function blocks in addition to using the following builders and tools:

- Domain Properties Setting Tool
  It selects the operating mode of Vnet/IP-Upstream.
- Message Cache Tool
  A group is defined when the network configuration of Vnet/IP-Upstream is in the narrow-band mode.
- Tag Name Builder
  You can enter tag name, and other information to the data to be handled in CI Server.

  When engineering by using iDefine, you can also define the tag names for FBs and variables by using iDefine. Use the reflection process from Generation Manager to reflect the definitions in Tag Name Builder. Tag names that were configured by using iDefine are read-only in Tag Name Builder.

A10.7 Engineering tools

The following describes the tools that are used after you have created a ProSafe-RS application:

Integrity Analyzer

The Integrity Analyzer is used to analyze the safety of existing created application logics. It detects unauthorized FB /FU as the safety function, and outputs results of analyzing on screen or on the analysis report.

Cross Reference Analyzer

It shows, on screen or on the analysis report, the difference between the application previously downloaded (which runs currently on SCS) and the application to be downloaded soon as well as the extent of impact in case of downloading. The Cross Reference Analyzer is for limiting the scope of retesting when application logic is modified.

Self-Documentation function

This is for printing user applications. The entire definitions of an SCS project or any parts can be selected as a printed item.

Project Attribute Tool

This tool can be used to display the attribute of an SCS project.

Test Project Creation Tool

This tool can be used to copy a project that is running at a plant site and create a project for test purpose.

Import/Export function

Import or export functions can be used to import or export SCS project data. Therefore, these data can be used for test functions or for reusing applications.

Project Comparing Tool

This tool can be used to detect the difference between two specified SCS projects and to display and print the result.

Version Control Tool

This is for controlling the version history of an SCS project to support the project updates by users.

By using Version Control Tool, you can save (check-in) the project data of an SCS project at a certain point upon adding a version number and restore (check-out) project data of a certain version. If you are performing I/O list engineering, start this tool from AD Organizer. If you start it from the Start menu, the data of AD Suite cannot be handled by the tool.

SEE ALSO For more information about precautions for handling an SCS project engineered by I/O list engineering that was checked in with Version Control Tool of a revision earlier than R4.03.10, refer to:

"■ Precautions for handling an SCS project that was checked in with Version Control Tool of a revision earlier than R4.03.10" on page C3-2

Master Database Restoring Function

This function is used to restore the contents of the master database as the work database. Use this function to discard changes made to the work database and use the master database as the data subject to engineering (work database). If you are performing I/O list engineering, start this tool from AD Organizer. If you start it from the Start menu, the data of AD Suite cannot be handled by the tool.

SEE ALSO For more information about precautions for restoring an SCS project that was generated by RS generation with AD Organizer of a revision earlier than R4.03.10, refer to:

"■ Precautions for restoring an SCS project that was generated by RS generation with AD Organizer of a revision earlier than R4.03.10" on page C3-2

Database Validity Check Tool

The Database Validity Check Tool is used to check the integrity of the database in the work database and master database of SCS project, and SCS database in SCS. The master database can be repaired if the master database has lost validity due to such as an error that has occurred during online change download. This repair function of the tool repairs the master database by replacing it with the work database.

SCS Information

This function is used to display and print SCS project usage conditions such as POUs used within the SCS and the number of variables. The number of licenses available is displayed separately for SIL 2 and SIL 3. This function can also be used to check the database revisions in the SCS project, number of project I/O licenses and their usage. You need to build an SCS project before using this function.

B. Designing applications

In the basic design of ProSafe-RS system configuration, you must consider the safety functions, architecture, installation method, and field I/O devices of the systems, as well as the management of documents and software.

B1. Key points of basic design

Having a proper basic design is very important for designing and building a safety instrumented system.

This section explains the important points to be considered for the basic design.

When the user has set a requirement for the safety integrity level (SIL), the requirement should be reviewed before calculating the PFD (Probability of Failure on Demand) of each safety loop in order to create a basic design that meets the required SIL.

Independence of safety instrumented system and process control system function

Establish independence of safety functions in a ProSafe-RS system and of control functions in a Process control system such as DCS.

Safety function and safety integrity

Consider the following items for Safety Function and Safety Integrity.

- Whether Redundancy for ProSafe-RS is needed or not (CPU and I/O modules)
- The failure rate of each component comprising the safety loop (Sensors, transmitters, relays, logic solver and final elements)
- Requirements for SIL and PFD value of a loop
- Interval between proof tests
- The possibility to easily perform validity check and proof tests for the applied system

Safety applications that can be used in ProSafe-RS

The ProSafe-RS system can primarily be used for the following applications.

- Emergency Shutdown System (ESD)
- Fire and Gas System (FGS)
- Burner Management System (BMS)

ProSafe-RS is capable of handling both applications configured of a combination of a NC (Normally-Closed) input and a DTS (De-energized-To-Safe) output and applications configured of a combination of a NO (Normally-Open) input and an ETS (Energized-To-Safe) output.

Architecture (basic functions)

Consider the following items for Architecture.

- Choice of “Normally Open (NO)” or “Normally Close (NC)”
- Choice of "Energized-to-Safe state principle (ETS)" or "De-energized-to-Safe state principle (DTS)"

IMPORTANT

It is recommended that SCS be separated into two SCSs. : One SCS with applications comprised of NC inputs and DTS outputs are performed. The other SCS with applications comprised of NO inputs and ETS outputs are performed.

- Redundant structure of safety loops
- Actions under fault conditions
- Safety time and scan period for process
- Requirements for Sequence Of Event Recorder (SOER) Data Collection and Time Synchronization System
- Man Machine Interface
- Requirements for each communication line
- Consideration for maintenance
- Maintenance override and bypass

Power supply and grounding

See and follow the ProSafe-RS Installation Guidance for installation.

SEE ALSO

For more information about power supply and grounding for SCS that supports SIL 3, refer to:

ProSafe-RS Installation Guidance (TI 32P01J10-01EN)

For more information about power supply and grounding for SCS that supports SIL 2, refer to:

ProSafe-RS Lite Installation Guidance (TI 32P51J10-01EN)

Common cause failure

Consider the distribution of functions of the ProSafe-RS system in order to deal with common cause failures.

Field input devices (sensors, transmitters and signal converters)

Consider the following items for field input devices:

- Number of points for each signal type (DI or AI)
- Independence from control system
- Process parameter in normal operation and trip point
- Redundancy of input devices: 1oo1, 1oo2, 2oo3 and 2oo4
- Failure rate of input devices, especially the dangerous failure rate
- Whether Wiring Check is needed or not

Field output devices (actuator, solenoid valve, shutdown valve, etc.)

Consider the following items for field output devices:

- Number of points for each signal type.(DO or AO, voltage value and current value separately)
- Independence from control system
- Choice of Actuator and final element, and their speed of actions (Open direction and Close direction)
- Redundancy of actuators and final elements
- Considering the case of using relay output
- Failure rate of actuators and final elements, especially the dangerous failure rate

- Whether Wiring Check is needed or not

Man machine interface

Consider the following items for the Man Machine Interface.

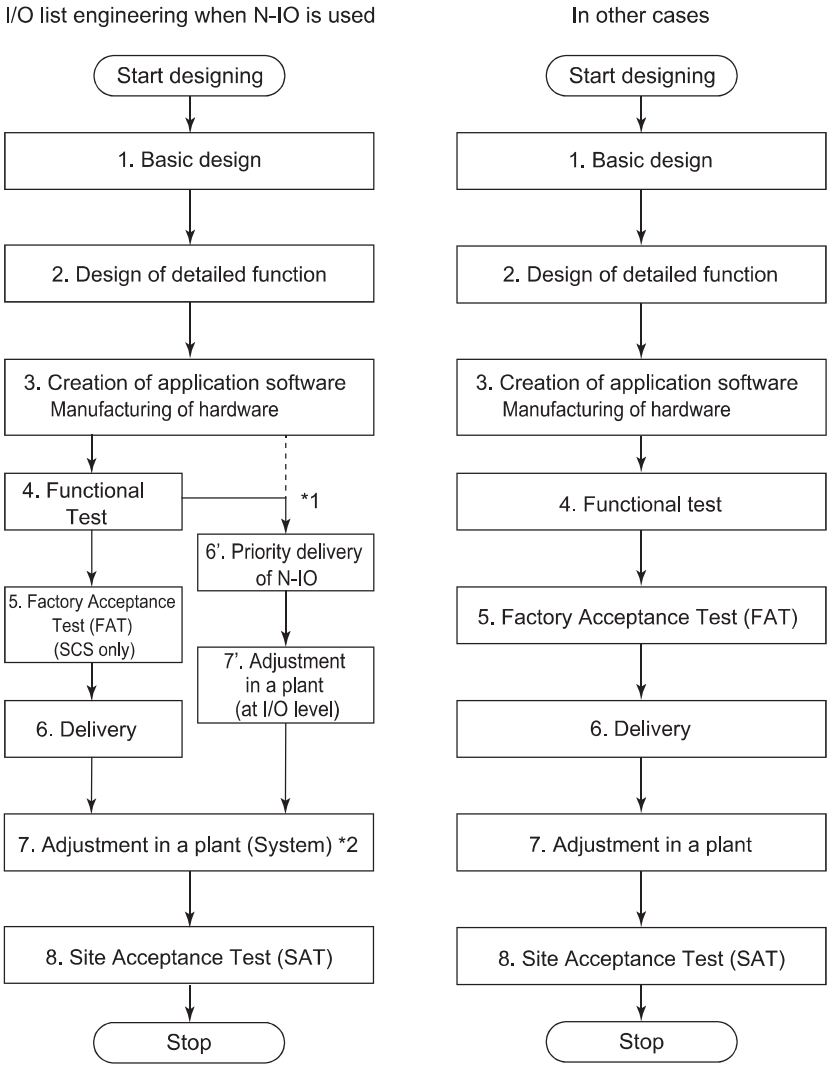
- For Operator Interface
  - Screens such as CRT and LCD
  - Annunciators:
    size of display/actions/colors/sounds
  - Switches and lamps for a monitoring board
  - Print items of a printer
- Manual shutdown
- Reset function on recovery
- Interface for maintenance and engineering
  - Configuration definition of system hardware
  - Building application logics and downloading them to SCS
  - Modification, testing and monitoring of the application logics
  - Maintenance override
  - Monitoring system status of SCS and diagnostic information
  - Controlling SCS security level
  - SOER

Management for design documents and software

Consider the following items.

- Print and storage management of design documents
- Management of changes for hardware and software

TIP



If you use iDefine, you can use the functional safety management (FSM) function of iDefine.

B2. Procedure for engineering

The regular engineering procedures from design to actually starting the operation, including production, inspection and commissioning, vary depending on the engineering method that you select and the type of nodes to be used.

If you are using N-IO and you have selected I/O list engineering, you can ship the N-IO before SCU. In the shipping destination, you can perform loop check between the N-IO and field devices first. The entire system is calibrated after the SCU has reached the shipping destination.

In all other cases, engineered SCUs and I/Os are shipped at the same time.

*1: You can flexibly decide the timing of priority delivery in a range from step 3 to 5 depending on the customer's request.
*2: Perform the remaining functional test items.

Figure B2-1 Procedure for engineering

1. In Basic Design, the following items should be decided based on user's requirements and specifications.
   - The making of safety specification
   - System configuration and hardware
   - The number of I/Os

- Safety Integrity Level (SIL) of loops
- Signal interface with another system

The following documents are made as a result of these work.

- Diagrams of the system structure
- Hardware specifications
- System basic design document
- Safety I/O list
- Safety communication I/O list
- List of interfaces with other systems (items not included in the safety communication I/O list)

2. Prepare a functional specifications document based on the user's requirements and specifications. Detailed logics such as shutdown logic and others are included in the functional specifications.
3. Create ProSafe-RS projects and applications on a computer installed with the SENG function. The hardware is also manufactured.

IMPORTANT

When prioritizing the N-IO delivery, you can flexibly decide the priority delivery timing in a range from step 3 to 5 depending on the customer's request.

4. Functions of the created application are checked. After making a document about the Test Specification, usually testing of functions is conducted in the following order.

   (1) Desk test

   The created applications are checked with self documents on the desk.

   ↓

   (2) Unit test-1

   Verify the created logic operations. You can use the SCS simulation test and logic simulation test environments on the computer for verification.

   ↓

   (3) Unit test-2

   In the target test using SCS, the overall logic etc. are verified.

   ↓

   (4) Integration test

   The integrated final test is conducted on the SCS target. Before the test, it is required to provide an environment, where SCS can be used, in combination with panel, console, a host computer and other subsystems. The testing for system failure such as hardware failure is also conducted.
5. Conduct the hardware and software Factory Acceptance Test (FAT) in the presence of the user. When prioritizing N-IO delivery, perform the Factory Acceptance Test (FAT) only for the SCS.

6'. When prioritizing N-IO delivery, deliver the N-IO hardware.

6. Deliver the hardware and software after they are confirmed by the users during FAT.

7'. When prioritizing N-IO delivery, calibrate the N-IO hardware that is installed on site.

7. Adjust the hardware and software that are installed on site through the system. When prioritizing N-IO delivery, perform tests on the remaining items of the function inspection.
8. Hand over the system to the user after conducting a final Site Acceptance Test (SAT).

TIP

iDefine can be used to create and test applications.

SEE ALSO

For more information about the engineering flow when using iDefine, refer to:

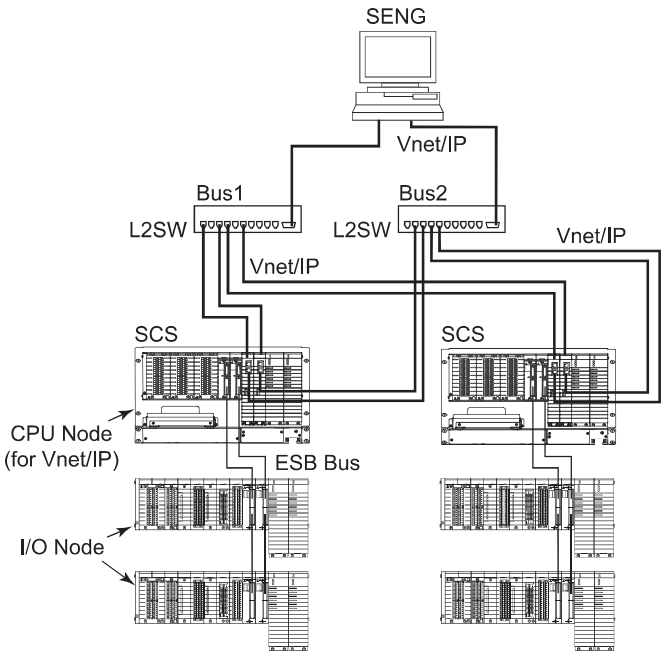
C2.2.3, “Engineering by using iDefine” on page C2-17

B3. Example of ProSafe-RS system configuration

This chapter describes the standard configuration of ProSafe-RS systems.

ProSafe-RS basic configuration

The basic configuration of ProSafe-RS consists of SENG and SCS. The following figure illustrates an example of the basic configuration of ProSafe-RS consisting of one SENG and two SCSs.



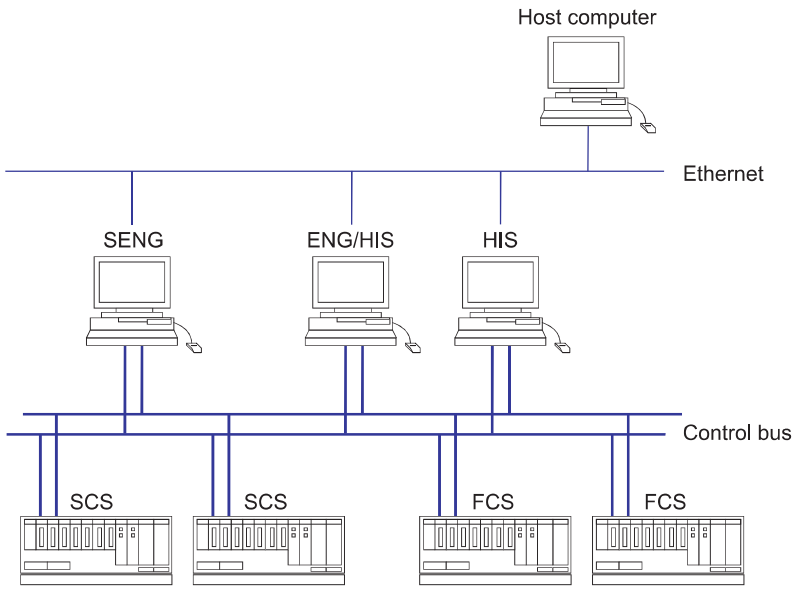
SCS and SENG are connected via control buses. Safety communication through control buses allows data to be sent and received between SCSs.

In SCS, I/O can be expanded by increasing the number of I/O nodes.

In the following figure, each of two SCSs has a Safety Control Unit (CPU node) which is connected to two Safety Node Unit (I/O nodes). I/O modules may also be installed in the CPU node.

Example of Vnet/IP system configuration

The following figure shows an example of the basic configuration of a ProSafe-RS system on a Vnet/IP network.



SCS: Safety Control Station to perform safety applications (for Vnet/IP)
SENG: PC for engineering functions like editing applications, downloading, tests and for maintenance.
L2SW: Layer 2 Switch

Figure B3-1 Example of a ProSafe-RS configuration

CENTUM integration configuration

The structure of a ProSafe-RS connected with CENTUM projects is called CENTUM Integration Configuration.

SCS: Control Station to perform safety applications
SENG: PC for engineering functions like editing applications, downloading, tests, and for maintenance.
FCS: Field Control Station to execute process control.
HIS: Human Interface Station
PC which provides interfaces for operators who monitor and operate the plant
ENG: PC installing CENTUM engineering function

Figure B3-2 CENTUM integration configuration

- For CENTUM Integration Configuration, both FCS and SCS can be operated and monitored from HIS.
  FCS can read or write data in SCS via Control bus. But the SCS is designed so that its safety function is not affected even when data is written by FCS.
- SCS engineering is performed from SENG. FCS and HIS engineering is performed from ENG. Engineering of CENTUM integration function is performed from both SENG and ENG.
  SENG functions, ENG functions and HIS functions can be installed in several PCs as well as to the same PC.
- The Exaopc OPC interface package of CENTUM (for installation on HIS) on HIS enables a host computer for production management, to access the data of FCS and SCS by using the OPC Interface.
  Moreover, using the ProSafe-RS SOE OPC interface package allows access to SOE information in SCS from the host computer.
- As a type of the CENTUM Integration Configuration, it is possible to connect only HIS function to ProSafe-RS.
  In this case, the structure is the same as in the previous figure without FCS.
- SENG is connected to control buses in CENTUM integration configuration. In addition, SENG, HIS and ENG terminals are connected via Ethernet.

Structure of connection with other systems

The SCS supports the Modbus slave communication function, subsystem communication function, safety subsystem communication function, and DNP3 communication function as functions for connecting with other systems. The Modbus slave communication function, subsystem communication function, and DNP3 communication function are interference-free functions. Safety subsystem communication is a safety communication but includes partially interference-free communication.

Connections with other systems are realized by installing communication modules in the SCS nodes. Application logic that is created for the communication functions of the Modbus slave

communication function, subsystem communication function, and DNP3 communication function cannot be used in safety loops.

The functions and configurations for connection are as follows.

- Modbus slave communication function
  In this configuration, an external system acts as an Modbus master and the SCS acts as a Modbus slave. You can, for example, construct an operator interface in other system by accessing data in the SCS from the other system that acts as the communication master. You can make redundant Modbus slave communication by creating a user application on the Modbus master.

  Serial communication modules or Ethernet communication modules need to be installed in the SCS nodes to be connected to other systems.

- Subsystem communication function
  The subsystem communication function allows the SCS to act as the communication master and communicate with other systems. The subsystem communication function of the SCS supports Modbus protocol. By using the SCS that acts as a communication master, you can read and set I/O data in the subsystems from the SCS. The subsystem communication can be made redundant.

  Serial communication modules or Ethernet communication modules need to be installed in the SCS nodes to be connected to other systems.

- Safety subsystem communication function
  The function within the safety subsystem communication function where the SCS serves as the communication master and connects with field devices by using fire and gas communication is referred to as the fire and gas communication function. This is a safety communication function which connects field devices with the SCS via communication modules and field wireless control stations, etc. Communication modules cannot be redundantly configured.

  Fire and gas communication modules are installed in SCS nodes to connect with field devices.

- DNP3 slave function
  The function using the DNP3 open protocol wherein the SCS operates as a DNP3 slave and communicates with a DNP3 master such as SCADA is referred to as the DNP3 slave function.

  The Ethernet communication module is installed in SCS nodes to connect to the DNP3 master.

The following figure shows an example of connection.

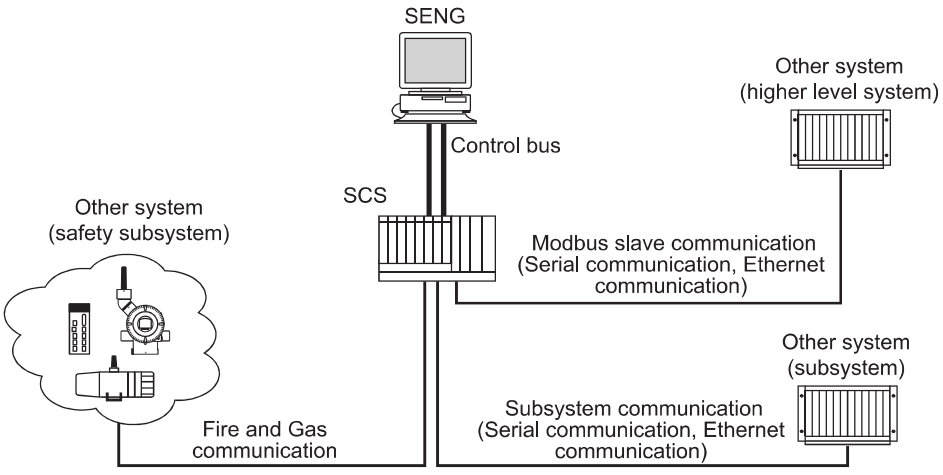


Figure B3-3 Connection with systems except CENTUM

Stand-alone SCS configuration

You can construct a stand-alone SCS configuration system environment without connecting to the Vnet/IP network when operating the SCS. The SCS and SENG can be connected temporarily via network while performing engineering and maintenance. The following figure shows a stand-alone SCS configuration system.

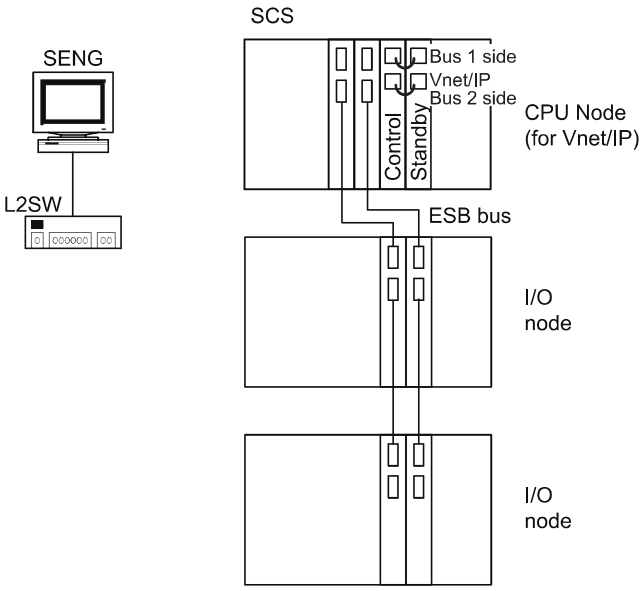

Figure B3-4 Stand-alone SCS configuration system

- Prepare an environment where an SENG can be connected to a stand-alone SCS for its maintenance. When connecting an SENG in a stand-alone SCS configuration environment, connect it to the SCS via a Layer 2 switch (L2SW).
- For maintenance, you need to connect an SENG to the SCS. Use network cables that are long enough for connection of the SENG.

IMPORTANT

- System status and errors should be notified by outputting them on a hardware-wired panel, or should be checked on the SCS State Management window on a connected SENG.
- In order to enable outputs automatically without using an SENG after turning on the power of the SCS, it is necessary to use SYS_STAT to perform the output enable operation from the application logic. The output module status is available through parameters such as the NRO parameter of SYS_IOALLST.
- While operating in a stand-alone configuration, the SCS itself becomes the Vnet/IP time master and its time may gradually deviate from the absolute time. Check the system time and adjust it accordingly when the SCS is connected to an SENG for maintenance and so forth.
- In a stand-alone SCS configuration system, do not turn on the power to the SCS when the battery of the CPU module has run out. If you do so, the date setting in the SCS will be changed to January 1st, 1970.

Size of system

The number of maximum connectable stations in the system which consists of stand-alone ProSafe-RS system and in ProSafe-RS integrated with CENTUM system is shown below respectively. Each system can be expanded as follows:

Number of stations (ProSafe-RS integrated with CENTUM)

- Connectable control bus: V net or Vnet/IP
- Number of connectable domains: 16
- Number of connectable stations in a domain: 64
- Number of connectable stations: 256
- Hierarchy: three-level hierarchy (three levels of control bus) (Up to two BCVs or two pairs of CGWs)

For HIS, 16 stations/domain at maximum.

For multiple domains, system generation function of CENTUM is required. In addition, V net requires BCVs and Vnet/IP requires Layer 3 switches.

Number of stations (stand-alone ProSafe-RS system)

- Connectable control bus: V net or Vnet/IP
- Number of connectable domains: 1
- Number of connectable stations in a domain: 64

A stand-alone ProSafe-RS system cannot be configured as a multiple-domain system. Only single-domain configuration is supported.

Vnet/IP domain connection specifications (when integrated with CENTUM)

Connect between Vnet/IP domains with a Layer 3 switch (L3SW) on each bus. This also requires the CENTUM system builder function.

- Number of connectable domains: 16 (Total of Vnet/IP domains and V net domains)
- Number of Layer 3 switches (L3SW) allowed: 15 levels

Connection specifications in a Vnet/IP domain (when integrated with CENTUM)

- Number of connectable Vnet/IP stations: Max. 64 (Vnet/IP stations including V net routers)
- General-purpose Ethernet communication devices: Max. 124 (PCs, Routers, etc.)
- Distance between stations in a Vnet/IP domain: Max. 40 km
- Distance between Layer 2 switch and a station: Max. 100 m (for Unshielded Twisted Pair (UTP))
- Distance between Layer 2 switches: Max. 5 km (for fiber-optic cable)
- Number of connectable Layer 2 switches in a domain: Max. 7 per each Bus. (Multilayer by cascade connection allowed)

B4. System reaction time

This section describes Reaction Time and PFD Calculation.

System reaction time

The system reaction time of SCS consists of the reaction time for the external demand (Demand reaction time) and the reaction time when a fault is detected in the SCS (Fault reaction time).

- Tr: system reaction time
- Tscan: scan period for application logic execution

Demand reaction time

The demand reaction time differs as follows, depending on whether the loop includes safety communication.

- When not using the inter-SCS safety communication

Figure B4-1 Reaction time 1

Tr = Tscan x 2 + Input processing time + Output processing time-Idle time

Idle time = Tscan - Application logic execution time

The output module processing time is shown in the following table.

Table B4-1 Output response time of the output module

Output module	Output response time
SDV531/L1DV531	30 ms
S2MMM843	110 ms for AO mode (90% response)
	30 ms for DO mode
S2MDV843	30 ms

- When using the inter-SCS safety communication
  When using the inter-SCS safety communication, the calculation formula varies depending on the relation between the scan periods of producer SCS and consumer SCS.
  - If Tscan on the producing side > Tscan on the consuming side:
    Tr = Tscan on the producing side x 2 + Tscan on the consuming side x 2 + transmission delay
  - If Tscan on the producing side ≤ Tscan on the consuming side:
    Tr = Tscan on the producing side x 2 + Tscan on the consuming side x 3 + transmission delay

  Transmission delay (For Vnet)
  - No BCV/CGW used: 10 ms
  - BCV/CGW used: number of BCV used x 50 ms + number of pairs of network levels via CGWs x 500 ms

  Transmission delay (Vnet/IP)

Table B4-2 Transmission delay in the case of Vnet/IP

Range	Mandatory values
Within a Vnet/IP domain	10 ms
Between Vnet/IP domains without a wide area connection (*1)	50 ms (Regardless of the number of L3SWs)
Between Vnet/IP domains with a wide area connection	250 ms (Regardless of the number of L3SWs and existence of WAC routers)
If the Vnet/IP domain and V net domain are connected using a V net router	Number of the hops of V net router x 50 ms

*1: Connecting two domains through wide-area network is called "wide area connection."

Figure B4-2 Reaction time 2

- When using SCS link transmission safety communication
  Tr= Sender Tscan x 2 + Receiver Tscan x 2 + Transmission Delay

  Transmission Delay: 100 ms
- When fire and gas communication is being used
  The demand reaction time is the total value of the following items (1) through (6):

Table B4-3 Demand reaction time when fire and gas communication is being used

Item	Description
(1) Time until GS01 detects the gas concentration	Refer to the GS01 User Manual.
(2) SCS reaction time	SCS reaction time = Tscan x 2 + Input processing time + Output processing time - Idle time Input processing time = 100 ms (for S2LP131) Idle time = Tscan - Application logic execution time
(3) Time until communication between S2LP131 and YFGW410 is restored after control rights of a redundant YFGW410 is switched over	5 seconds. This time includes the 1 second for switching of YFGW410 to be completed. In the following cases, the time is 0 seconds: • When YFGW410 is of a single configuration • When assuming that detection of gas and switching of YFGW410 will not occur at the same time
(4) PROFIsafe communication time from the SCS to GS01	8 seconds is recommended.
(5) PROFIsafe communication time from GS01 to the SCS	Always 2 seconds.
(6) SCS reaction time	Same as the description for (2).

Fault reaction time

How to calculate the fault reaction time of the ProSafe-RS system is shown as follows:

- In the case of faults within the Safety Control Station

  Basically, fault reaction time (maximum) is calculated by the following formula:

  Tr = (Fault detection time) + Tscan × 2 + Output module processing time - Idle time

  In the formula, the maximum value (of fault detection time) is as follows for each module.

Table B4-4 Fault detection dime of each I/O module

I/O module types	Fault detection time
SDV144, SDV521, SDV531, SDV526, SDV541, SDV53A, L1DV144, L1DV521, L1DV531, L1DV526, L1DV541, and L1DV53A	520 ms
SAI143, SAI533, L1AI143, L1AI533	600 ms
SAV144, L1AV144	1360 ms
SAT145, SAR145, L1AT145, L1AR145	2100 ms
S2MMM843	600 ms for AI mode, AO mode
	520 ms for DI mode, DO mode
S2MDV843	520 ms

The fault reaction time for the fault in communication between CPU module and output module is shown in the following formulas:

- Tr = 1 s (Tscan =< 250 ms)
- Tr = Tscan x 2 + 0.5 s (Tscan > 250 ms)

After the time (Tr above) passed since the faults, the output module outputs the Output value at fault.

- For failures involving a field device or wiring
  You need to enter the values specified in following table in the (fault detection time) of the previously mentioned formula only when calculating the fault reaction time for the following types of faults. Both are maximum values.

Table B4-5 Fault detection time of field wiring and devices

Type of Fault	Module	Fault detection time (Maximum)
Short circuit between channels	SDV144, SDV521, SDV531, SDV541, SDV53A, L1DV144, L1DV521, L1DV531, L1DV541, and L1DV53A	1.46 s (*1)
	SAI533, L1AI533	0.6 s
Short circuit in output wiring (while outputting OFF signals)	SDV531, SDV541, L1DV531, L1DV541	1.46 s (*1)
	SDV521, L1DV521	10 s (*1) (*2)
	SDV53A, L1DV53A	10 s (*1) (*3)
	DO mode of S2MMM843, S2MDV843	1.6 s(*4)
Open circuit	SAT145, SAR145, L1AT145, L1AR145	1.5 s(*5)
	DO mode of S2MMM843, S2MDV843	1.6 s(*6)
Inputting the signal out of the range	SDV144, L1AV144	1.02 s (*7)
	DI mode of S2MMM843, S2MDV843	1.02 s (*7)
Open circuit or short circuit with the power supply line (while sending OFF signal)	SDV526, L1DV526	302 s
Overload of field device	SDV526, L1DV526	1.5 s

*1: Can be detected only when the pulse test is enabled.
*2: Value for style S3 and above.

*3: Value for style S2 and above.
*4: Can be detected only when low voltage pulse test (on) is enabled.
*5: Can be detected only when burnout detection is enabled.
*6: Can be detected only when detect disconnection and low voltage pulse test (on) is enabled.
*7: This value applies when the modules are in dual redundant configuration. The value for non-redundant configuration is 520 ms as noted in the above explanation.

- Inter-SCS safety communication
  The reaction time while using inter-SCS safety communication is the timeout period that is specified in the FB for inter-SCS safety communication.

  Tr = OUTT + DLYT

  - OUTT: Reception Interval Timeout value
  - DLYT: Transmission Delay Timeout Value

- SCS link transmission safety communication
  The reaction time while using SCS link transmission safety communication is the timeout period that is specified for the receiver SCS.

  Tr = OUTT + DLYT

  - OUTT: Reception Interval Timeout value
  - DLYT: Transmission Delay Timeout Value

- Fire and gas communication
  The fault reaction time when fire and gas communication is being used is the total value of the following items (1) through (3):

Table B4-6 Fault reaction time when fire and gas communication is being used

Item	Description
(1) PROFIsafeWatchDogTime with communication immediately prior to the gas concentration being reflected onto the output value of GS01	30 to 60 s
(2) PROFIsafeWatchDogTime with communication after the gas concentration being reflected onto the output value of GS01	30 to 60 s
(3) SCS reaction time	SCS reaction time = Tscan x 2 + Input processing time + Output processing time - Idle time Input processing time = 100 ms (for S2LP131) Idle time = Tscan - Application logic execution time

SEE ALSO For more information about setting OUTT and DLYT, refer to:

- "● Inter-SCS safety communication timeout settings" in "■ Precaution for engineering" in A7., "Inter-SCS safety communication" in Engineering Guide Vol. 2 (IM 32P01C20-01EN)
- "■ Definition of receive data" in A6.2, "Data structure and definition of the SCS link transmission" in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

Example of calculating the Fault Reaction Time (Tr)

Conditions:

Scan period of application logic: 200 ms

Idle time: 30%

DO module: SDV531 (output response time = 30 ms)

- Case 1 (Fault with the DI module)
  Tr (max.) = 520 ms + 200 ms x 2 + 30 ms – (200 ms x 0.3) = 890 ms
- Case 2 (Communication fault between the CPU module and the output module)
  Tr (max.) = 1 s (because Tscan < 250 ms)

- Case 3 (Short circuit fault between DI channels)
  Tr (max.) = 1460 ms + 200 ms x 2 + 30 ms – (200 ms x 0.3) = 1830 ms

PFD calculation

The average PFD (System PFDavg) of a system is calculated with the model in the following figure.

System PFDavg = Sensors PFDavg + Controller PFDavg + Valves PFDavg

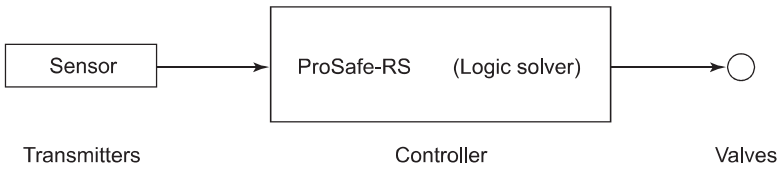

Figure B4-3 PFD calculation model

For ProSafe-RS (SIL 3), when the interval between proof tests is 10 years and the DIO module is used, the Controller PFDavg is indicated as follows.

Controller PFDavg = 6.63×10^{-6}

Further information about PFD calculation is available on request.

C. Basics of creating applications

This part describes the preparations common to all engineering methods of ProSafe-RS, the procedures for creating applications for each engineering method, precautions, analysis tools, and test methods in the following order:

1. Preparing the project
   This section describes how to prepare the AD Server to create a new project for SCS engineering and register the project in the AD Server.
2. Work flow for creating applications
   The work flow to define I/O and creating applications differs depending on the engineering method used. This section describes the work flow and main points of creating applications for each engineering method.
3. Precautions when creating applications
   This section describes the precautions when creating applications.
4. Procedures for generating a database
   After creating the application, generate a database. This section describes the method and precautions for generating a database.
5. Testing with the Safety Analyzer
   After generating the database, test the application by using the Safety Analyzer. This section describes the Safety Analyzer.
6. Simulation tests
   Run tests using simulators if necessary. This section describes simulation tests.
7. Offline download to the system
   Offline download the created application to SCS. This section describes the offline download.
8. Output enable operation
   After performing the output enable operation, values from the application are sent from the output module. This section describes the enable output operation.
9. Target tests
   The created application must undergo target testing. This section describes target tests.

C1. Preparing the project

After the preparation for the AD Server is complete, prepare the project. This section explains the type of projects that need to be prepared and how to prepare them.

C1.1 Type of project

ProSafe-RS has the following types of projects:

- AD project
  It is a project for managing multiple RS projects in the AD Server.
- RS project
  It is a project for managing multiple SCS projects. You can view the status of SCS projects which are included in the same RS project by using the SCS Maintenance Support Tool.
- SCS project
  It is a project that corresponds to a single SCS and is the smallest project unit.

The following figure shows the relationship between the actual SCS and each project type.

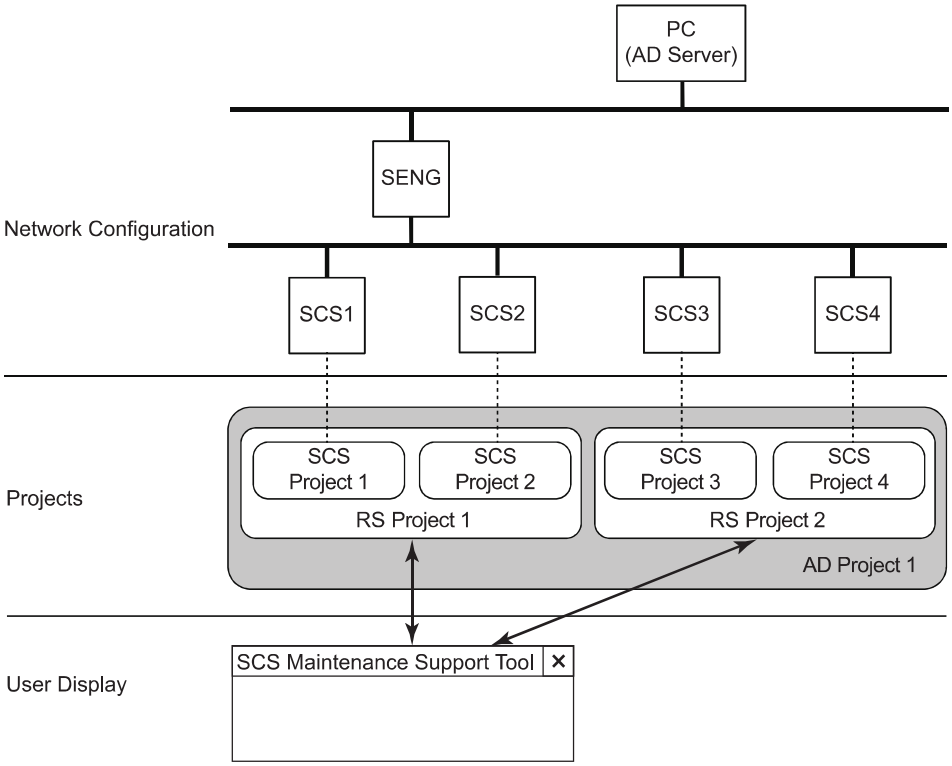

Figure C1.1-1 Relationship between the actual SCS and each project type

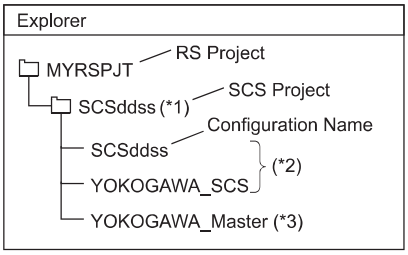
For integration with a CENTUM system, a definition to associate the CENTUM Project with SCS Project is required.

In addition to these projects, there are library projects where the engineering data can be used as a library. You can also register library projects in AD projects.

Relationship between SCS project and RS project



An SCS project is included in an RS project. One SCS project, which is always included in one RS project, is not shared with another RS project. In addition, an RS project is not included in another RS project.

Folder configuration of SCS project and RS project

The SCS projects that constitute an RS project are specified by the folder configuration.

- RS Project
  A folder created in Windows Explorer

- SCS Project
  A folder created by using the SCS Manager under an RS project folder. It is placed as one folder.

*1: The folder name must be identical to the SCS project name. (dd: Domain number, ss: Station number)
*2: This is a work database.
*3: This is a master database.

Figure C1.1-2 Folder configuration of SCS project and RS project

C1.1.1 AD project

It is a project for managing multiple RS projects. The engineering data of AD Suite is managed per AD project.

I/O licenses are counted for all SCSs contained in the RS projects that are registered in one AD project.

The following figure shows the relationship between the ProSafe-RS license project and the AD project.

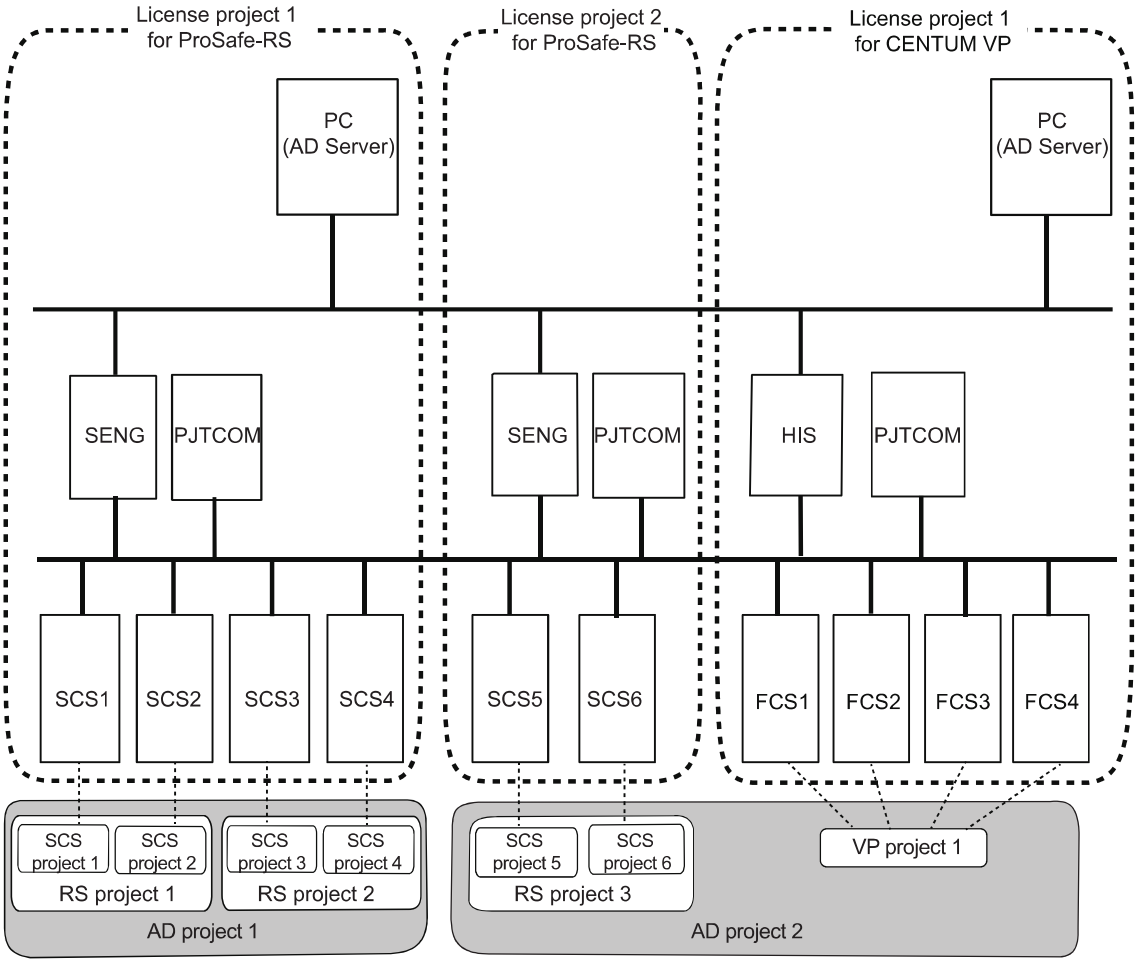


Figure C1.1.1-1 Relationship between the ProSafe-RS license project and the AD project

If the number of I/O points exceed the number of licenses, you will not be able to download SCS projects to the SCS. Use the SCS information display function to check the number of licenses.

SEE ALSO

For more information about the SCS information display function, refer to:

"■ Checking the usage status of I/O licenses" in F1., "Display SCS information" in Engineer's Reference Manual (IM 32P04B10-01EN)

C1.1.2 RS project

An RS project is a combination of several SCS projects in order to bundle engineering data of SCS projects. Defining an RS project permits the collective monitoring of the status of the constituent SCSs by using the SCS Maintenance Support Function.

You must register all RS projects that involve the SCSs to which a license of the same license project is assigned in a single AD project.

C1.1.3 SCS projects

You need to define one SCS project for each SCS. An SCS has an attribute and contains the following databases:

- Work database (SCS database and source files)
- Master database (running SCS database and source files)

■ SCS project attribute

An SCS project will be defined with the following three attributes.

The attributes of a project determine whether it can be downloaded to actual SCS and whether it can be tested by SCS simulation. However, a logic simulation test can be preformed for any project regardless of its attribute.

● Default project

A new project created in the SCS Manager will be the default project. The default project should be a project that has not been downloaded to the actual SCS. Engineering works for a new project are always carried out on the default project.

Downloading to the actual SCS: Always use offline download

Testing by SCS simulation test: Available

After offline download to the actual SCS has been completed successfully, the attribute of the project will change from Default Project to Current Project automatically.

● Current project

If the offline download to the actual SCS is completed successfully at least once, the attribute of the project will change to Current Project.

Downloading to the actual SCS: Available

Testing by SCS simulation test: Unavailable

● User-defined project

The attribute of a project created by using the Test Project Creation Tool is User-Defined Project.

SCS simulation tests cannot be run on the current project. To check the changes made to the application through the SCS simulation test, copy the current project by using the Test Project Creation Tool and test the changes using the copied project. Based on the scale of the changes made, decide whether to make a copy after modifying the current project or modify the project after copying.

Downloading to the actual SCS: Unavailable

Testing by SCS simulation test: Available

SEE ALSO For more information about reflecting the changes made to a user-defined project in the current project, refer to:

"■ Operations required after SCS simulation tests (user-defined project)" in 3.1.2, "Engineering procedure after SCS simulation tests" in Test Function Guide (IM 32P04B30-01EN)

■ Configuration and functions of SCS project database

In ProSafe-RS, one SCS project is defined and managed for each SCS. The following data are stored in each SCS project folder.

- Work database

- Master database

The following shows the components and related functions of an SCS project.

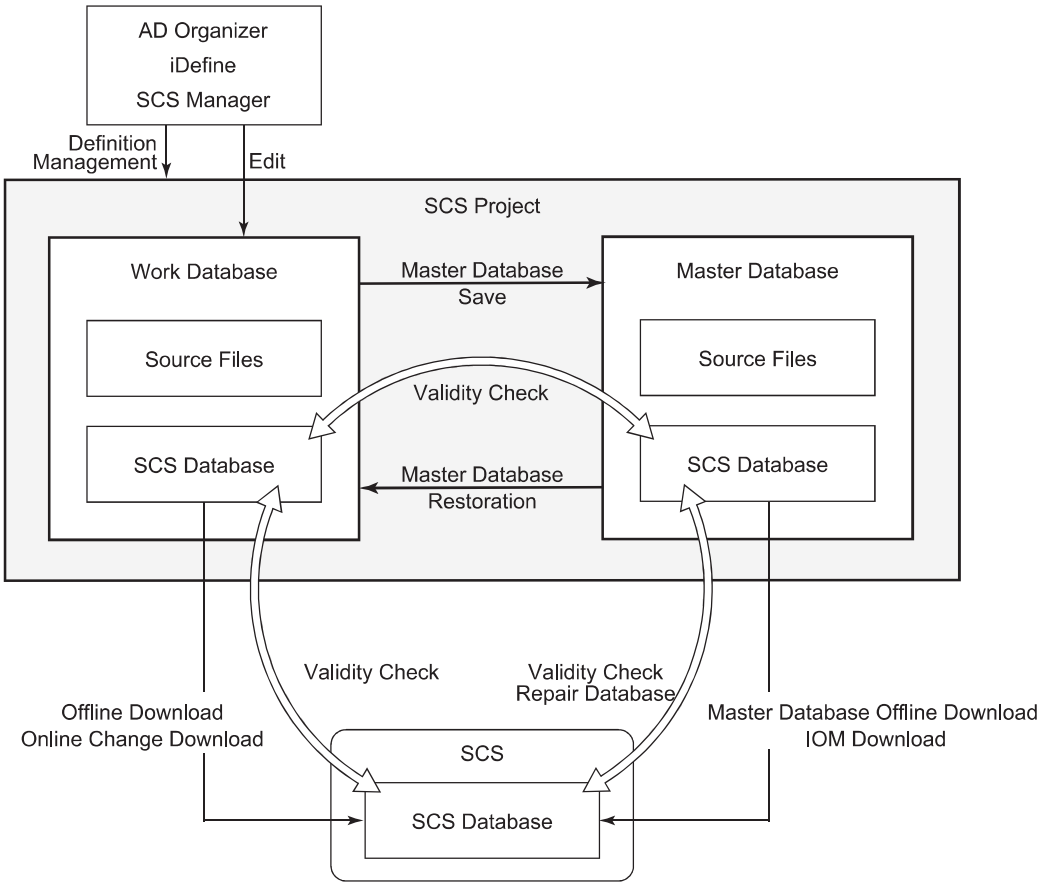

Figure C1.1.3-1 Configuration of SCS project

Work database

The SCS database with the edited content reflected on it and its source files are called work database.

After applications are edited using SCS Manager, Multi-Language Editor, or Builders, the source files will be created.

When performing I/O list engineering, the results are reflected in the work database when the data is edited in AD Organizer and the reflection process is run. You can edit by using iDefine in addition to AD Organizer.

The SCS database is created if you run RS generation from AD Organizer or if you build from SCS Manager.

Master database

The master database refers to the running SCS database and a group of its base source file group at the time when the SCS database is downloaded to the SCS via offline download or online change download.

The master database is also used both online change download and to detect differences from the work database by Cross Reference Analyzer.

IMPORTANT

Do not edit the master database using Windows explorer.

Master database saving function

This function automatically saves the contents of the work database to the master database when the SCS database is downloaded to the SCS via offline download or online change download, and retains it at all times in SCS projects. Therefore you do not need to upload the database from the SCS to SENG.

Master database restoring function

The Master Database Restoring function is provided as a function to delete the work database that is being edited and restore the contents of the master database as the work database.

Database validity check tool function

You can check the validity among the master database, work database, and the SCS database that is downloaded to the SCS. You can also eliminate any inconsistencies in the databases. This function is provided as the Database Validity Check Tool.

Editing rules and purpose of SCS project database

The rules to follow when editing SCS projects are as follows:

- You cannot open multiple SCS Managers on one SENG at the same time.
- You can use one SENG to edit the SCS projects that are stored on another SENG. However, you cannot operate the same SCS project from several SENGs at the same time.

The master database and the work database are separated, so the following is possible:

- The user can perform monitoring based on the master database running on an SCS regardless of whether the work database is being modified or not.
- Even if an SCS hardware failure occurs and a CPU module and/or input/output module require replacement, the user can restore the SCS application by master database offline download and IOM download.
- The user can restore the work database from the master database in order to cancel changes made to the SCS project.

SEE ALSO For more information about the function for downloading the master database onto SCS, refer to:

- I4.4, “Master database offline download” on page I4-76
- F4., “Master Database Restoring Function” in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about precautions for restoring an SCS project that was generated by RS generation with AD Organizer of a revision earlier than R4.03.10, refer to:

“■ Precautions for restoring an SCS project that was generated by RS generation with AD Organizer of a revision earlier than R4.03.10” on page C3-2

C1.1.4 Library project

A library project is a project database that can be used as a library independent of the specific SCS. Library projects can be used for creating application logics and can be debugged only by a logic simulation test. (An individual library project cannot be tested by SCS simulation test or by target test for debugging.)

The functions and function blocks that are used among two or more SCSs can be created as library projects and be copied to each SCS project.

When engineering by using iDefine, library projects cannot be used.

C1.2 Procedures for creating projects

Follow these steps to prepare the project data. Use the same steps for both the RS original engineering method and the I/O list engineering method.

1. Set the location of ADMDB by using the ADS Administration Tool.
2. Create an AD project by using the ADS Administration Tool.
3. Configure the user management and access control by using the ADS Administration Tool.
4. Connect to the AD project by using the ADS Administration Tool.
5. Create an RS project folder by using Windows Explorer.
6. Register the RS project to the AD project by using AD Organizer.

TIP

Even if you have selected RS original engineering, register RS projects to AD projects. You can also register RS projects that include SCS projects that were created before introducing AD Suite.

7. Call SCS Manager from AD Organizer and create an SCS project.

TIP

When creating an SCS project, you select a station type and an engineering method. You cannot change the engineering method later.

SEE ALSO

For more information about ADMDB location configuration, refer to:

C1.1.4, “Setting the location of the ADMDB” in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about creating AD projects, refer to:

C1.2.1, “Creating and deleting AD projects” in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about configuring user management and access control, refer to:

C1.2.2, “Controlling access to AD projects” in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about procedures to connect AD projects to the AD Server, refer to:

C1.2.1, “Connecting to AD projects” on page C1-11

For more information about creating RS projects, refer to:

C1.2.2, “Creating RS projects” on page C1-12

For more information about procedures for registering RS projects in an AD project, refer to:

C1.2.3, “Registering RS projects in the AD project” on page C1-13

For more information about SCS project creation procedure, refer to:

C1.2.4, “Creating SCS projects” on page C1-15

C1.2.1 Connecting to AD projects

After you complete the project registration, user management, and definition of access control on the AD Server, you must configure the settings for connection from AD Organizer to the AD project.

You need to perform the following procedure for setting:

1. Start AD Organizer.
   When AD Organizer is started for the first time, the Select AD Project dialog box appears.
2. When AD Organizer is not started for the first time, select [File] > [Change AD Project] from the menu bar on AD Organizer.
   The Select AD Project dialog box appears.
3. Enter the computer name or IP address of the AD Server, and then click [Connect].
   A connection is established to the specified AD Server and a list of AD projects that are found on the corresponding AD Server is displayed.
4. Select the target AD projects, and then click [Save Settings].
   If a logged-in user of AD Organizer is registered in the target project, the connection request succeeds, the Select AD Project dialog box closes, and the project information is displayed in AD Organizer.

SEE ALSO

For more information about project registration with AD Server, refer to:

“● Project registration” in “■ Server processing and status of the ADMDB at the time of the ADMDB location setting” in C1.1.3, “ADMDB location setting” in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about defining user management and access control with AD Server, refer to:

C1.2.2, “Controlling access to AD projects” in Engineer's Reference Manual (IM 32P04B10-01EN)

C1.2.2 Creating RS projects

When you install ProSafe-RS software, a folder for an RS project is automatically created. You can also create another RS project.

You need to set the folder of the RS project as a shared folder.

Initial status of RS projects

When you install ProSafe-RS software, one RS project is automatically created as the `C:\RS-Projects\MYRSPJT` folder. When this folder is used as is, you do not need to create a new RS project.

Operations when sharing an RS project

You need to set the automatically created RS-Projects folder of `C:\RS-Projects` as a shared folder, or create an RS project under a shared folder.

Creation of new RS projects

It is possible to create new RS projects in addition to the RS project created at the installation. In this case, use Windows Explorer to create a folder with the name of new RS project. The folder name is used as the name of the RS project. The following restrictions apply to the folder name.

- Folder name: Up to 8 single-byte characters, starting with an upper case alphabet character
- Characters that can be used: Single-byte alphabet characters in upper case, numerals, underscore and hyphen
- Absolute path of the folder: The path to the RS project folder cannot contain the following characters:
  Single-byte space, `\, /, :, ;, *, ?, ", <, >, |, .`

TIP

Keep the absolute path of the folder as short as possible. If an error occurs due to a restriction in the file name length of Windows, review the length of the following names as well:

- Length of the absolute path of RS projects
- Length of the library project name
- Length of the library project configuration name
- Length of the library project resource name

C1.2.3 Registering RS projects in the AD project

After creating a folder of RS projects, you can use AD Organizer to register RS projects in the AD project.

You must register all RS projects that involve SCSs to which a license of the same license project is assigned in the same AD project. This registration enables you to correctly count the number of I/Os in the scope of the ProSafe-RS license project. After registering the RS project to an AD project, do not copy, move, or delete the RS project using Windows Explorer. In addition, make sure to use AD Organizer when you create a backup of the RS project.

You need to perform the following procedure to register RS projects in the AD project:

1. Start AD Organizer.
2. On the System Structure Navigator, select [Register System Project] from the sub menu. The System Project Registration dialog box appears.

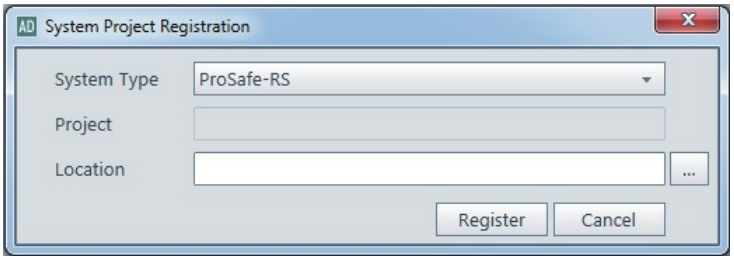

Figure C1.2.3-1 Project registration screen

3. Configure the settings as follows:

System type	Select ProSafe-RS.
Project	A folder that is created for RS projects is displayed. You cannot configure the settings.
Location	Set the location of RS projects.

4. Click the [Register] button.

Editing RS project properties

You need to perform the following procedure to edit the properties of the RS project:

1. Select the RS project displayed on the System Structure Navigator and select [Properties] in context menu.
   The Properties tab appears.
2. Edit items.
3. Click the [OK] button.

Unregistering RS projects

You need to perform the following procedure to unregister RS projects:

1. In the System Structure Navigator, select the RS project.
2. From the sub menu, select [Unregister System Project].
   The RS project in the AD project is unregistered.

Reflecting the changes in RS projects to the data in AD Organizer

The settings such as RS project definition and station are edited in SCS Manager and saved in ADMDB and RS project database. After registering or unregistering an RS project or editing

its properties, you need to perform the following operation to update the system information of System Structure Navigator in AD Organizer.

- From the menu bar of AD Organizer, select [View] > [Refresh].

C1.2.4 Creating SCS projects

You need to start SCS Manager from the System Configuration Navigator of AD Organizer and use the new SCS project creation function to create a new SCS Project.

The generated information is stored in the RS project database and ADMDB. In AD Organizer, when the update is done by using the System Structure Navigator, the latest status appears.

SCS project creation procedure

This section describes the procedures to create an SCS project.
To create a new SCS project, launch SCS Manager from AD Organizer and configure the following settings:

Do not use Windows Explorer functions to copy or move the SCS projects that you have created.

1. Setting an SCS project folder
   Set a folder in which to store the SCS project data.
2. Setting SCS project items
   Set Domain number and Station number etc. of the SCS project. Some of the items can only be specified in the process of creating a new SCS project and others can be changed later.
3. Setting a resource
   A resource refers to a set of SCS application logics. In this step, the resource name and resource number are specified. In ProSafe-RS, one resource can be set for one SCS.
4. Setting a configuration
   A configuration refers to a software object corresponding to one SCS. The configuration name is specified in this step. In ProSafe-RS, one configuration can be set for one SCS. A configuration includes a resource.
5. Setting an IP address
   Specify an address related to TCP/IP communication of the SCS.
6. Setting SCS constants
   Specify SCS constants.

Setting an SCS project folder

Follow these steps to create an SCS project:

1. From AD Organizer, start SCS Manager and select [File] > [New Project/Library] from the menu bar.
   The New dialog box appears.
2. Enter the following details:

Destination folder:	Folder where the SCS project is saved
Name:	SCS project name `SCSddss` dd denotes Domain number, and ss denotes Station number.
Comment:	64 characters or less
Template:	`SCS_Default_Target`

Create SCS project folders directly under RS project folder.

SEE ALSO For more information about details on SCS project folder settings, refer to:

"Working with projects" in "Workbench" in the Workbench User's Guide

Setting SCS project items

When the SCS project folder has been configured, the SCS Project Properties dialog box appears. Configure the settings related to the SCS and project on the [SCS] tab and the [Project] tab of this dialog box.
In the SCS Project Properties dialog box, the [I/O List Engineering] check box appears. This check box becomes available when you select a Station Type to which I/O list engineering is applicable. If you select the check box, the I/O list engineering is applied. If you create an SCS with this check box clear, RS original engineering is applied. You cannot change the engineering method later.

SCSP3/SCSL2/SCSP2/SCSP1/SCSU1can be a target of I/O list engineering.

When the system is integrated with CENTUM, specify a CENTUM project folder on the [Project] tab.

SEE ALSO For more information about details on SCS Project Properties dialog box, refer to:

C1.2.5, “SCS Project Properties dialog box” on page C1-18

Setting a resource

A resource refers to a set of application logics created by the user. Multiple programs can be run in one resource. Only one resource can be run in one SCS.
Right click the resource on Link Architecture View and then choose [Properties] from the pop-up menu so as to display the Resource Properties dialog box. The resource name and the resource number can be defined on the General tab. Specify "SCSddss" for the resource name and "ddss" (dd: domain number, ss: station number) for the resource number.

SEE ALSO For more information about details on resource settings, refer to:

"Resources" in "Link architecture view" in "Workbench" in the Workbench User's Guide

Setting a configuration

In order to execute an application logic set, it is necessary to specify the hardware configuration of each SCS.
Right click the configuration on Hardware Architecture View and then choose [Properties] from the pop-up menu so as to display the Configuration Properties dialog box. The configuration name can be defined on General tab.

Specify "SCSddss" (dd: domain number, ss: station number) for the configuration name.

SEE ALSO For more information about details on configuration settings, refer to:

"Configuration properties" in "Hardware Architecture View" in "Workbench" in the Workbench User's Guide

Setting an IP address

The IP address can be defined on Hardware Architecture View. Double click "Connection" so as to display Connection - Properties dialog box. The IP address needs to be set for "Value" item.
In the standard, the IP address sets "172.16.dd.ss" (dd: domain number, ss: station number).

SEE ALSO For more information about details on IP address settings, refer to:

"Connections" in "Hardware Architecture View" in "Workbench" in the Workbench User's Guide

Setting SCS constants

Specify constant values for SCS and parameters for communicating with external systems in SCS Constants Builder.

SEE ALSO For more information about details on SCS Constants Builder, refer to:

C1.2.6, “SCS Constants Builder” on page C1-21

C1.2.5 SCS Project Properties dialog box

The SCS Project Properties dialog box is used to make various basic settings for an SCS, including domain number and station number.

Calling the SCS Project Properties dialog box

The SCS Project Properties dialog box appears if you perform the following operations in SCS Manager.

- When a new SCS project is created
  The SCS Project Properties dialog box appears automatically when the SCS project folder settings are completed.
- When a menu is selected from the Engineering launcher menu of SCS Manager
  To edit an SCS project after it is created, select [Engineering] from the [Tools] menu of SCS Manager. The Engineering launcher menu appears; select [SCS Project Properties].

Components of the SCS Project Properties dialog box

The SCS Project Properties dialog box has the following components.

SCS tab

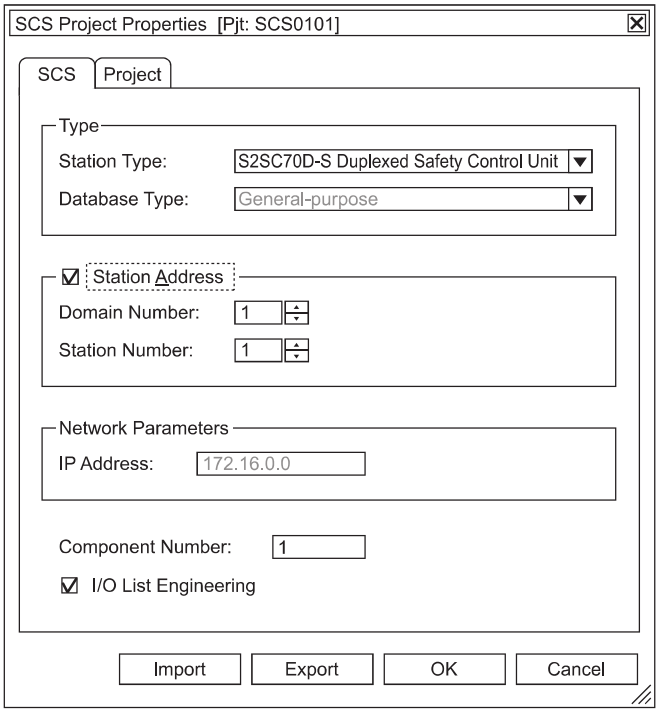

Figure C1.2.5-1 SCS tab

The table below shows the components of the "SCS" tab.

Table C1.2.5-1 Setting items in the "SCS" tab

Item	Setting (*1)	Description
Station Type	Only possible when a new project is created	Specify the model of the SCS station.
Database Type	Display only	Database type is displayed.

Continues on the next page

Table C1.2.5-1 Setting items in the "SCS" tab (Table continued)

Item	Setting (*1)	Description
Station Address	Yes	Select the check box to allow setting the domain number and station number. The check box is selected by default when a new project is created. The check box is not selected by default when this dialog box is opened from the Engineering launcher menu.
Domain Number	Yes	Specify the domain number. Select a value using the spin box or enter a character string directly. A value in the range from 1 to 31 can be specified.
Station Number	Yes	Specify the station number. Select a value using the spin box or enter a character string directly. A value in the range from 1 to 64 can be specified.
IP Address	Display only	The IP address set in Hardware Architecture View is displayed.
Component Number	Yes	Enter the component number. (*2) Up to 4 characters, which can be any alphanumeric characters, can be entered.
I/O List Engineering	You can configure the settings only when creating a new project.	Specify whether to use the I/O list engineering method

*1: Yes: Setting possible
*2: This is a number assigned to identify the devices belonging to an RS project. It is assigned when installing an SCS in a cabinet, etc., and used to show the connection origin and destination of each cable when wiring cables.

IMPORTANT

- Make sure to specify the station type and engineering method when creating a new SCS project. They cannot be changed later.
- After you have defined the station address (domain number and station number), try not to change it if possible. Changing the station address deletes the master database.

Project tab

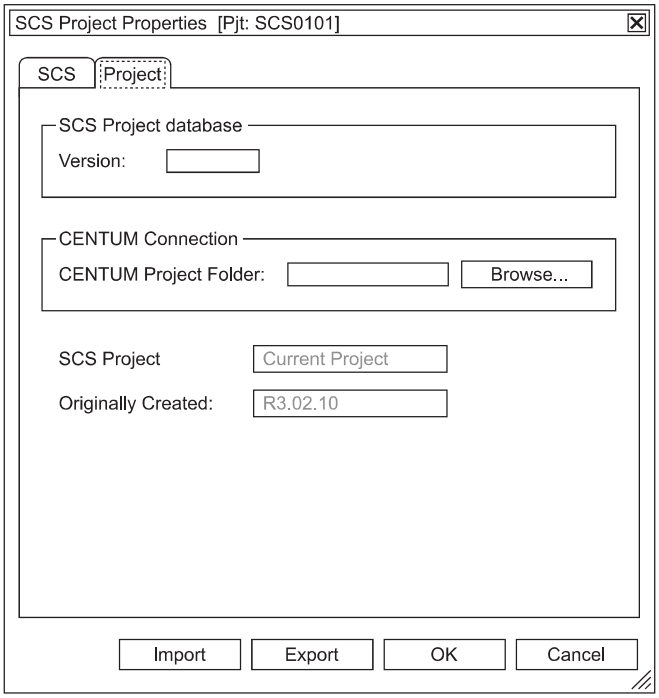

Figure C1.2.5-2 Project tab

The table below shows the components of the "Projects" tab.

Table C1.2.5-2 Setting items in the projects tab

Item	Setting (*1)	Description
Version	Display only	The version number is displayed if the versions of the project data are maintained. The field is blank in the case of an SCS project that has never been checked in with Version Control Tool.
CENTUM Project Folder	Yes	Specify the top folder of the CENTUM project. Enter the path directly or specify the path from the Folder Selection dialog box that is displayed by clicking [Browse]. (*2) (*3) This is valid only when a license for the CENTUM VP Integration Package has been assigned to the PC.
SCS Project	Display only	Displays SCS project attribute. Project Attribute: Default Project, Current Project, User-Defined Project
Originally Created	Display only (*4)	Displays the software revision number of the SENG that the project was created from.

*1: Yes: Setting possible
*2: If the entire length of the specified path cannot be displayed in the text edit box, the middle part of the path is omitted and displayed as [...].
*3: A path specified in the local drives format is automatically converted to a path in UNC format.
*4: If the project was created in SENG with a software revision number prior to R1.03, the software revision number cannot be displayed.

TIP

SCS Project Properties dialog box is available for both SCS project and Library project. It differs in the SCS project properties dialog box of Library project as follows:

- This dialog box will not automatically start when the project is newly created.
- When started from SCS Manager, only "Project" tab will be displayed.
- There is no need to specify [CENTUM Project Folder].
- [Default Project] will be displayed as SCS Project.

C1.2.6 SCS Constants Builder

SCS Constants Builder is used to specify constant values for SCS and parameters for communicating with external systems.

Calling SCS Constants Builder

Select [Engineering] from [Tools] menu of SCS Manager. When the Engineering launcher menu appears, select [SCS Constants Builder]. The SCS Constants Builder starts.

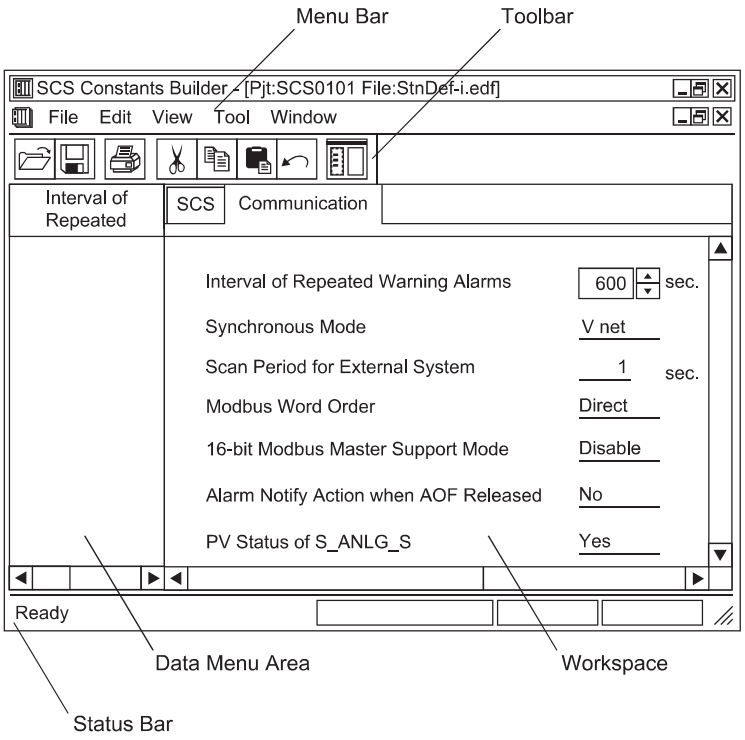

Figure C1.2.6-1 Communication tab of SCS Constants Builder window

SCS Constants Builder contains the following tab sheets:

- SCS tab
  For common setting parameters related to SCS
- Communication tab
  For setting parameters related to communication with external systems

SEE ALSO For more information about menu bar, toolbar, data menu area, and message display area, refer to:

A4.1, “Window components common to builders” in ProSafe-RS User’s Guide (IM 32P01B10-01EN)

SCS tab

On the SCS tab, you can set the following items:

Optical ESB Bus Repeater: SCSV1/SCSP1

Select [Yes] if you use the Optical ESB Bus Repeater. [No] if not. The initial setting is [No].

Maximum Extension Distance: SCSV1/SCSP1

Set the Maximum Extension Distance for the Optical ESB Bus Repeater.

If Optical ESB Bus Repeater is set to [Yes] for SCSP1, the maximum distance can be set within the range from 5 to 50 km in 5 km units. If Optical ESB Bus Repeater is set to [Yes] for SCSV1, [5 km] can be set. The initial setting is 5 km.

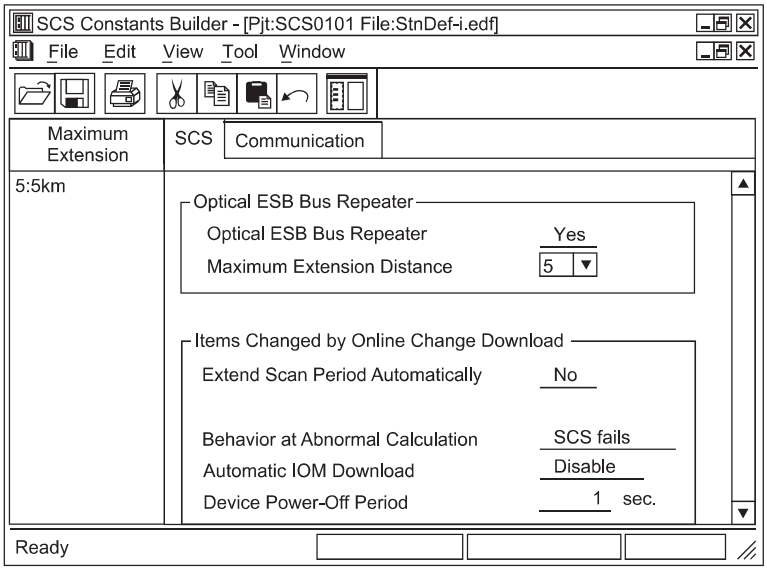

Figure C1.2.6-2 SCS tab of SCS Constants Builder

SEE ALSO For more information about specifying the SCSP1 node extension distance, refer to:

Appendix 1.1, “Setting items for nodes” on page App.1-2

Extend Scan Period Automatically

Select [Yes] or [No] to set whether to adjust the scan period of the application logic automatically. The default setting is [No]. If set to [Yes], the scan period will be extended automatically when the execution time of the application logic has extended the scan period specified on the SENG for some reasons. This prevents the communication performed by the SCS, for example, inter-SCS safety communication, from being discontinued. This setting is changeable by online change download.

SEE ALSO For more information about details on setting and checking the scan period of the application logic, refer to:

A7.2, “Automatic extension function for scan period of the application logic execution function” on page A7-5

Behavior at Abnormal Calculation

Select [SCS fails] or [SCS continues] to set the behavior of the SCS when an abnormal calculation has occurred in the application logic. The default setting is [SCS fails]. This setting is changeable by online change download.

SEE ALSO For more information about details on specifying the behavior at abnormal calculation, refer to:

G2.1.3, “Behavior at abnormal calculation” on page G2-7

Locking of Internal Variables: SCSP3/SCSL2/SCSP2

You can select [Enable] or [Disable] to set whether to lock the internal variables that are used in the application logic. This setting is displayed only when the SCS type is SCSP3, SCSL2, or SCSP2 and [Extend Scan Period Automatically] is set to [Yes]. By default, it is set to [Disable]. You can change this setting by online change download.

SEE ALSO For more information about details on locking internal variables, refer to:

"■ Locking internal variables" in F8.1, "Variable locking" in Engineer's Reference Manual (IM 32P04B10-01EN)

Automatic IOM Download

Select [Enable] or [Disable] to set whether to enable automatic IOM download. The default setting is [Disable]. This setting is changeable by online change download.

SEE ALSO For more information about Automatic IOM download details, refer to:

"■ Automatic execution of IOM download" on page I4-81

Device Power-Off Period

This item is used to reset the Smoke and Heat Detector.

You can set the number of seconds until the power ON command is output from when the function block HSDTR outputs a power OFF command. This is the number of seconds for which the Smoke and Heat Detector is power OFF. This setting is changeable by online change download.

- Setting range: 1 to 10 (seconds) (default: 1)

TIP This setting is displayed when using an SCS project newly created with a version of SENG that is R4.03.00 or later. However, this is not displayed with SCSV1. When importing an SCS project created with a version of SENG that is earlier than R4.03.00, an import error will occur with this item and the value will be set to 1.

Device Startup Waiting Period

This item is used to reset the Smoke and Heat Detector.

You can set the number of seconds until startup is completed from when the power of the Smoke and Heat Detector is turned ON. When there are multiple types of devices and equipment in the station, enter the maximum number of seconds. This setting is changeable by online change download.

- Setting range: 0 to 60 (seconds) (default: 0)

TIP This setting is displayed when using an SCS project newly created with a version of SENG that is R4.03.00 or later. However, this is not displayed with SCSV1. When an SCS project created with a version of SENG that is earlier than R4.03.00 is imported, this value is set to 0.

Alarm Suppression During Device Reset

This item is used to suppress the alarm during the reset status of the Smoke and Heat Detector.

You can set whether or not to suppress the display of system alarms and process alarms while the Smoke and Heat Detector is in the reset status. Set the value to [Enable] to suppress the display of system alarms and process alarms, or set the value to [Disable] to not suppress the display. This item cannot be changed by online change download.

TIP This setting is displayed when using an SCS project newly created with a version of SENG that is R4.03.00 or later. However, this is not displayed with SCSV1 and SCSU1. When an SCS project created with a version of SENG that is earlier than R4.03.00 is imported, this value is set to [Disable].

SEE ALSO For more information about engineering for resetting the Smoke and Heat Detector, refer to:

A3.4.4, “Engineering regarding the device reset function and alarm suppression during device reset” in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

Command Line

TIP Specify the command line with no more than 256 single-byte characters. If the command line is not set, the default value is used for each applicable item. The format is as follows:

Item name = Data value, Item name = Data value, ...

- PSINITIM (Fire and gas communication startup time)
  This item is the time required to initialize fire and gas communication during the SCS start-up processing. Before the initialization of fire and gas communication is completed, the data status of the data obtained by the communication is BAD. Therefore, specify this time to delay the completion of the startup of SCS. This setting is applicable to SCS in which one or more S2LP131 are defined.

  The number entered here is the communication cycle for GS01. The conversion from the GS01 communication cycle to the fire and gas communication startup time is implemented internally within the SCS.

  The formula is as follows:

  Fire and gas communication startup time (s) = 20 + (GS01 communication cycle + 8) x 4

  When the GS01 communication cycle is 12 seconds, the fire and gas communication startup time is 100 seconds.

  - Format
    PSINITIM=12
  - Parameter
    The configurable range is 8 to 30 seconds. The default value is 12 seconds.

Settings with the Communication Tab

On the Communication tab, you can set the following items:

Interval of Repeated Warning Alarms

This item should be set in the case of a CENTUM integration structure.

Set the time from the occurrence of a process alarm to the next occurrence of the same alarm. Repeated warning alarms are intended to notify the engineer that serious process alarms are existing continuously.

If the cause of an alarm still persists after a certain time has elapsed from the occurrence of the alarm, the process alarm message is sent again, regardless of whether or not the alarm is acknowledged.

The interval of repeated warning alarms can be specified in the range from 0 to 3600 seconds. The initial setting is 600 seconds.

If 0 is specified for the interval of repeated warning alarms, repeated warning alarms are disabled.

Synchronous Mode

This item allows specifying the method of synchronizing system time. The time of the SCS is used for the time stamps of messages recorded in SOERs.

For SCSV1, two options [IRIG-B] and [V net] are provided for time synchronization. The default is [V net].

For SCSP3/SCSL2/SCSP2/SCSP1, it is Vnet/IP time synchronization.

Table C1.2.6-1 Time Synchronous Mode

Method	Description
IRIG-B time synchronization	The time information is acquired from the externally installed GPS clock through IRIG-B and set to the CPU and I/O module. The GPS clock and CPU nodes of all SCSs are connected by IRIG-B. Specify this option when highly accurate synchronization is required for discrete input module time between different SCSs.
V net time synchronization	This method sets Vnet time to the CPU and I/O module. The Vnet time is also recorded in SOER.
Vnet/IP	This method sets Vnet/IP time to the CPU and I/O module. The Vnet/IP time is also recorded in SOER. If the SNTP server is connected to Vnet/IP network, the Vnet/IP time synchronizes with the SNTP server time.

Scan Period for External System

Specify the scan period used when connecting to external systems such as CENTUM. The scan period for external system setting refers to the operating period at which the connection function is executed.
Select either 1 second or 2 seconds. Default: 1 second.

Modbus Word Order

When establishing a connection with an external system and acquiring 32-bit data from the external system, the order of the most significant word and least significant word can be changed. Select either the order of the most significant word and then the least significant word, or the reverse order. The reverse order is used generally in Modbus. [Direct] is selected by default.

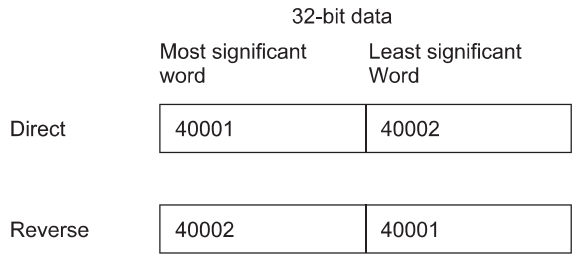

Figure C1.2.6-3 Modbus Word Order

16-bit Modbus Master Support Mode

This item specifies whether to allow the following accesses by the external Modbus master in Modbus slave communications.

These accesses are allowed when 16-bit Modbus master support mode is set to [Enable]. By default, it is set to [Disable].

- Write to a single holding register
  Function code is 06.
- Read 16-bit data
  Function codes are 03 and 04.
- Write 16-bit data
  Function code is 16.

Alarm Notify Action when AOF Released

This item should be set in the case of a CENTUM integration structure.
Specify to (or not to) output the suppressed messages when AOF is deactivated.

When you output the suppressed process alarm message, you need to set this setting to [Yes], otherwise, you can set this setting to [No]. By default, this setting is [No].

SEE ALSO For more information about activating/deactivating alarm suppression, refer to:

B8.2.4, “Alarm inhibition (AOF)” in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

● PV Status of S_ANLG_S

This setting item is used for a CENTUM integration structure.
With this setting, whether to keep the PV status on the mapping block (S_ANLG_S) of ANLG_S (Analog Input Block with Data Status) can be defined. If you want to have BAD data status on the mapping block S_ANLG_S when the data status of IN terminal of ANLG_S block is BAD, you need to set this setting to [Yes], otherwise, you can set this setting to [No]. By default, this setting is [Yes].

● The first number of annunciator messages with tag name

You can specify the first number of annunciator messages with tag name (%AN).

The numbers from the specified number up to the maximum number of annunciator messages are used for annunciator messages with tag name.

However, if you specify 0 as the first number, all the numbers are used for annunciator messages instead of annunciator messages with tag name.

- For SCSP1/SCSU1: 0 to 1000
- For SCSP3/SCSL2/SCSP2: 0 to 2000

The initial setting is 0. It is not displayed in SCSV1.

● DNP3 Slave Function

When you use the DNP3 slave function, you need to set it to Enable, otherwise, you can set it to Disable. By default, it is set to Disable.

TIP This setting is displayed only for the SCS projects of SCSU1 that are created by the software version R3.02.20 or later. When the SCS projects that are created by the software prior to R3.02.20 are imported, this setting is set to Disable.

● Skip password dialog box for manual operation FB

This setting determines whether to skip the Password Input dialog box in HIS for MOA/MOB_11/MOB_21 FB when an empty string constant (′′) (two apostrophes) is specified in an input terminal (PSWD) that is used to set the password.

Set [No] if you do not want to skip the Password Input dialog box and [Yes] if you do. The initial value is [No] and the input dialog box is displayed even if the password is an empty string constant.

You can change this setting by online change download. This is not displayed for SCSV1 and SCSU1.

■ Change process alarm name of Analog Input Block with Data Status

The alarm name of the ANLG_S (Analog Input Block with Data Status) can be changed so as to match the alarm name on the diagnosis information window and SOE Viewer with the alarm name of CENTUM.

Before changing the alarm name, the CENTUM process alarm text strings need to be modified first. For more information about defining the process alarm text strings, please contact Yokogawa agents.

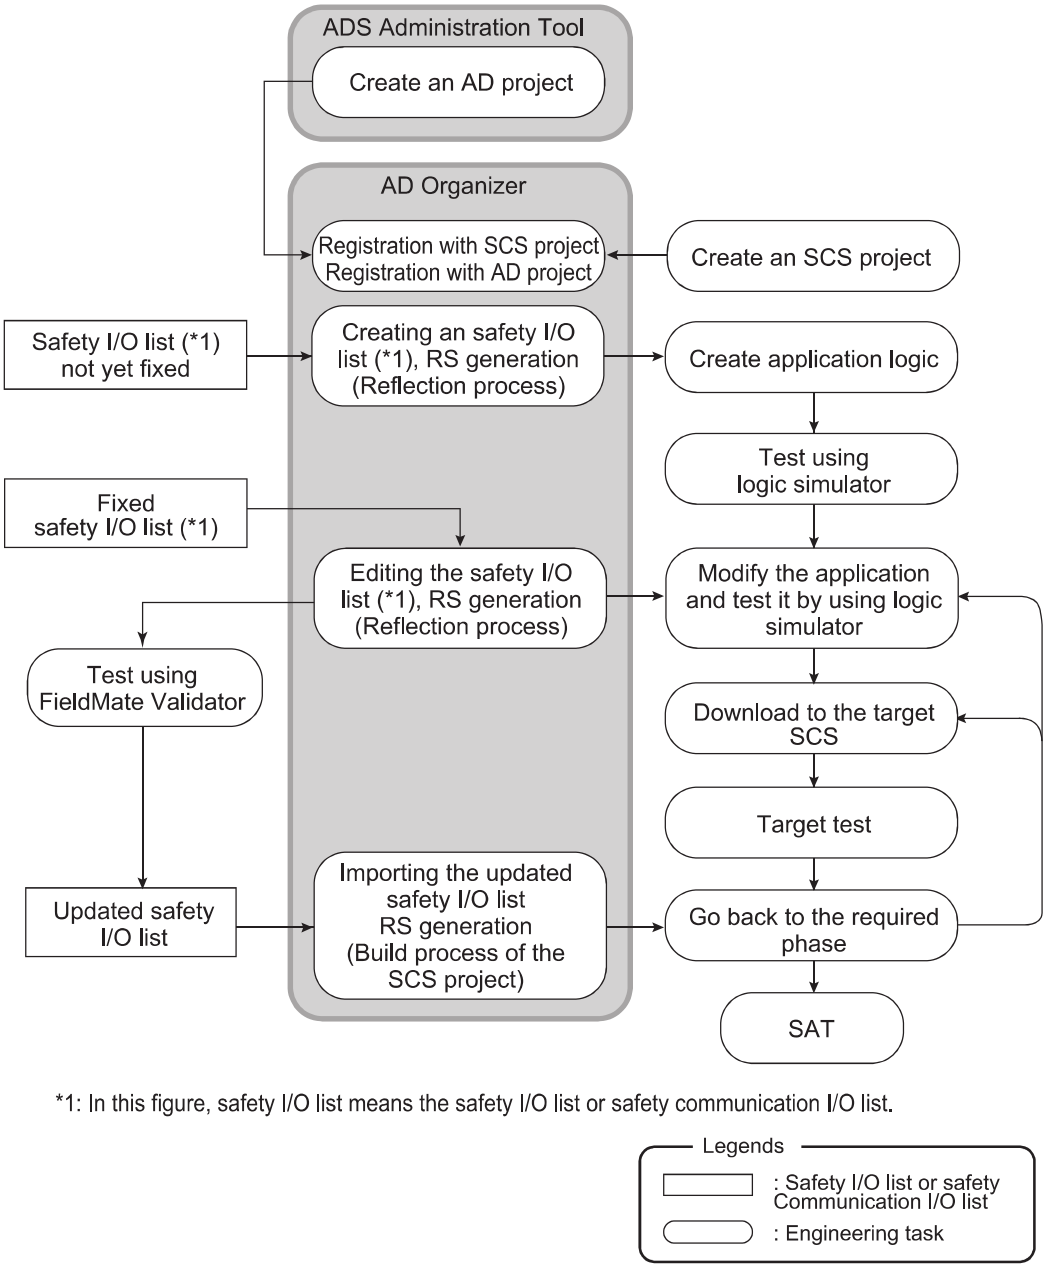
IMPORTANT

When applying this feature, if the SCS project to be monitored on CENTUM contains both ANLGI and ANLG_S blocks, the ANLGI blocks should be changed to ANLG_S blocks.

C2. Work flow of creating applications for each engineering method

After preparing the project, create applications by using the engineering functions.

The procedures for creating applications differ for each engineering method.



This chapter explains the engineering procedures and main points for each engineering method.

For modifying the application, it is necessary to analyze any effects caused by the modifications in advance and take the required measures against the effects.

C2.1 Work flow of I/O list engineering

This chapter explains the engineering flow of the I/O list engineering method. I/O list engineering is used even when you use iDefine as an engineering tool. Read the following section if you are using iDefine.

The following figure shows the engineering flow when using the AD Suite, SCS Manager, and FieldMate Validator. This flow describes only the differences from the flow of RS original engineering. By using FieldMate Validator, you can configure and adjust the I/O channels of universal type I/O modules without using the SCU.

*1: In this figure, safety I/O list means the safety I/O list or safety communication I/O list.

Figure C2.1-1 Engineering flow in AD Suite

SEE ALSO For more information about steps for I/O list engineering, refer to:

D., “Procedures to create applications using the I/O list engineering method” on page D-1

For more information about operations that are necessary when using iDefine, refer to:

C2.2, “Work flow of I/O list engineering with iDefine” on page C2-11

Engineering using a safety I/O list and safety communication I/O list

The safety application is a function element that can operate and control the plant in a safe manner, and is built mostly by using application logics based on input/out variables.

You can start building an application logic with the I/O variables being reflected onto Dictionary View from a safety I/O list and safety communication I/O list as long as you do not use iDefine as the engineering tool.

Handling of the safety I/O list and safety communication I/O list

The user can use the safety I/O list or safety communication I/O list to make definitions based on the P&ID tag name in the application, and proceed to build the application without having to wait for the detailed design of I/O modules or data communication.

The required information varies depending on whether the I/O addresses are set in the safety I/O list or safety communication I/O list.

When the I/O address is not set, the following information is required to create an application logic by using the safety I/O list or safety communication I/O list.

- Information required for the safety I/O list
  - P&ID tag name
  - I/O type (AI, AO, DI, DO)
  - I/O Tag
  - Signal Type
  - P&ID Group

  Information required to reflect variables onto Dictionary View is as follows:
  - P&ID tag name
  - I/O type (AI, AO, DI, DO)
  - I/O Tag
  - Data Type
  - P&ID Group
- Information required for the safety communication I/O list
  - P&ID tag name
  - I/O type (AI, AO, DI, DO)
  - Signal Protocol
  - I/O Tag
  - P&ID Group

  Information required to reflect variables onto Dictionary View is as follows:
  - P&ID tag name
  - I/O type (AI, AO, DI, DO)

    - Data Type
    - Signal Protocol
    - P&ID Group

  The type of the FB is decided as soon as the following information is decided:

    - I/O type (AI, AO, DI, DO)
    - Signal Protocol
    - Data Type

The P&ID tag name and the I/O type are mandatory to save the safety I/O list and safety communication I/O list.

When a safety I/O list or safety communication I/O list that contains I/O addresses is read by AD Organizer, IOM definitions are created by operating Create Node & IOM in IOM Definition Editor. The required information is as follows:

- Information required for the safety I/O list
    - SCS project name
    - RS project name
    - Node type
    - Node number
    - IOM category
    - IOM type
    - Unit number
    - Slot number
    - Terminal number
    - Signal type
- Information required for the safety communication I/O list
    - SCS project name
    - RS project name
    - Node type
    - Node number
    - IOM category
    - IOM type
    - Slot number

TIP

Even in a situation where the IOM definitions are not yet complete, the user can perform the reflection process in order to be able to define variables of safety I/O in POUs in the SCS project.

IMPORTANT

When using S2MMM843 or S2MDV843 in an explosion protection system, refer to the following document without fail because the approved values of the explosion protection parameters are different depending on the signal type.

ProSafe-RS/ProSafe-RS Lite Explosion Protection (TI 32S01J30-01E)

P&ID tag and P&ID group

The P&ID tag is a name that identifies an I/O point. The I/O points are identified by using the P&ID tag as the key while defining the I/O information for each line in the safety I/O list. The P&ID tag needs to be uniquely defined in the P&ID group.

The P&ID group is the label name required for identifying the safety I/O list or safety communication I/O list. The P&ID group name is used as the file name that is created under the I/O-List folder of the system configuration navigator of AD Organizer.

I/O Tag

The I/O Tag is a name that identifies an I/O point. The I/O Tag needs to be uniquely defined.

Engineering procedures for SCS I/O

This section describes the work flow for engineering regarding inputs/outputs.

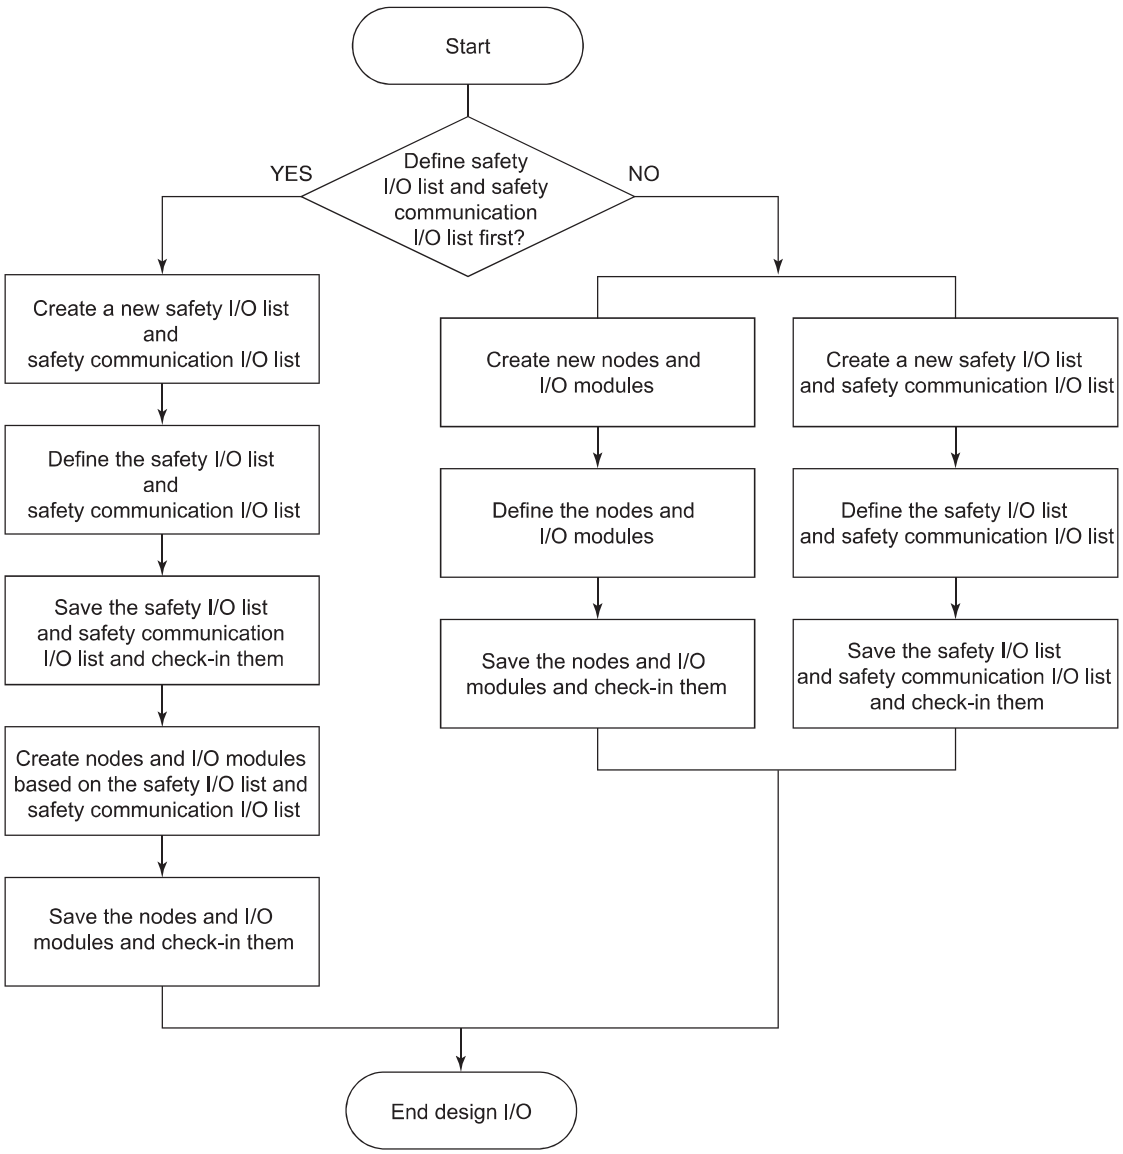


Figure C2.1-2 Work flow for engineering regarding inputs/outputs

The safety I/O list and safety communication I/O list can be created before or at the same time as an I/O module. By creating the safety I/O list and safety communication I/O list in advance, an application can be built alongside an I/O design.

Editor and tools that are used for I/O list engineering

The following table shows the editors and tools used when performing I/O list engineering.

You can start the SCS Manager from the System Structure Navigator in AD Organizer.

Table C2.1-1 Editor and tools that are used in I/O list engineering

Category	Operation	Means to operate editors and tools SCS Manager/AD Organizer	Editor or tool name	Remarks
Safety application	Safety logic definition	SCS Manager	Multi-Language Editor (*1)	-
	Variables and parameters definition	SCS Manager	Dictionary View (*1)	I/O variables are automatically created from the safety I/O list. Instances of subsystem communication I/O FB, PROFINET communication input FB, and fire and gas communication input FB are automatically generated from the safety communication I/O list. Internal variables and FB instances can be defined by iDefine.
I/O	I/O list definition	AD Organizer	Safety I/O Editor Safety Communication I/O Editor	The following information is generated: • Dictionary View • I/O Wiring View • I/O Parameter Builder • Communication I/O Builder
	Node/IOM detailed definition	AD Organizer	IOM Definition Editor	The information for the following is created: • I/O Wiring View • I/O Parameter Builder
System	Creation of SCS projects	SCS Manager	SCS Manager	The contents will be reflected in the AD Organizer.
	SCS project attribute	SCS Manager	SCS Project Properties	
	SCS constant definition	SCS Manager	SCS Constants Builder	-
	SCS parameter setting	SCS Manager	Hardware Architecture View	-
	POU definition	SCS Manager	Link Architecture View (*1)	-
	Safety communication association	SCS Manager	Binding List View	-
	SCS Link transmission data definition	SCS Manager	SCS Link Transmission Builder	-

Continues on the next page

Table C2.1-1 Editor and tools that are used in I/O list engineering (Table continued)

Category	Operation	Means to operate editors and tools SCS Manager/AD Organizer	Editor or tool name	Remarks
RS generation	Database generation	AD Organizer	RS Generation Manager	-

DNP3 communication	DNP3 slave definition	SCS Manager	DNP3 Communication Builder	-

*1: iDefine can be used as well.

Procedure for I/O list engineering without iDefine

The procedure for I/O list engineering without using iDefine is described as follows. The AD project is defined as a prerequisite.

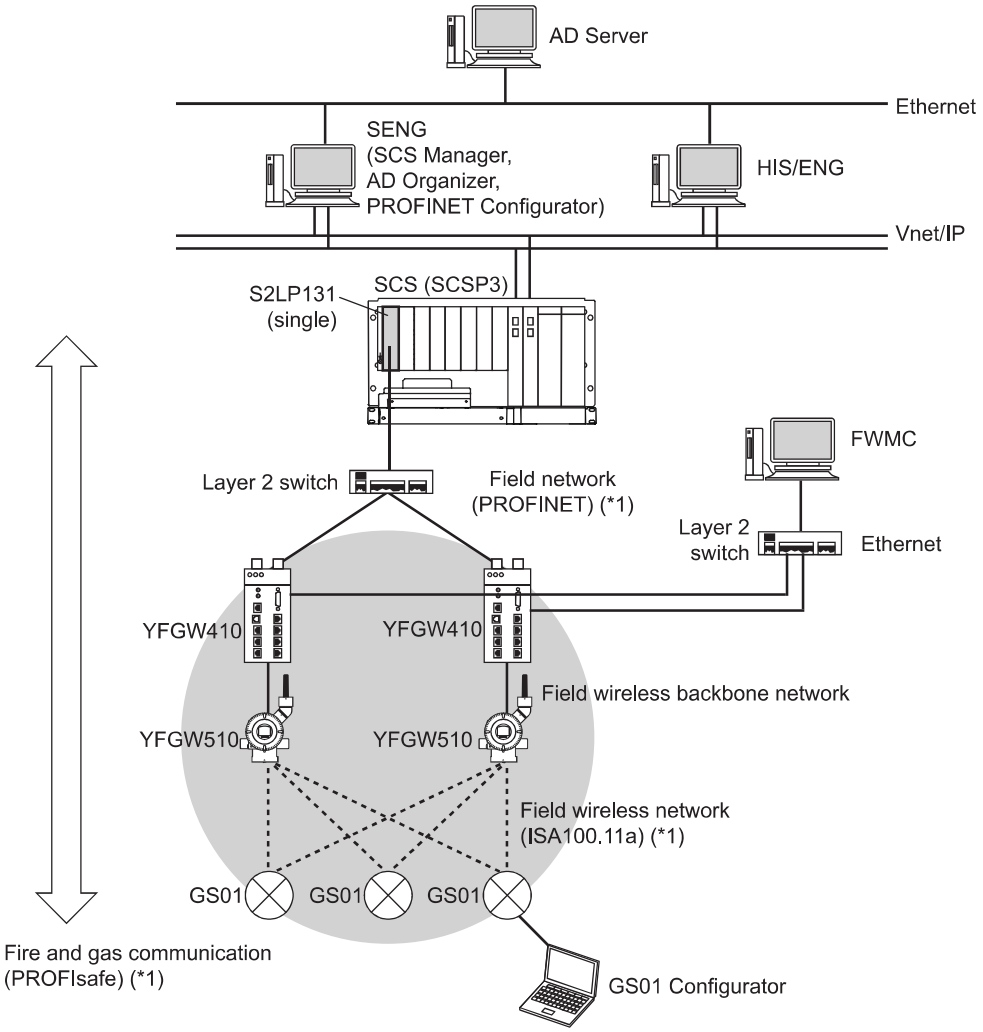
1. Configure the I/O modules and I/O variables.
   Import the safety I/O list or safety communication I/O list and then add or modify I/O variables by using AD Organizer. Define the I/O modules and I/O parameters as well.
2. When using the fire and gas communication function, define fire and gas communication modules and fire and gas communication.
3. Select an SCS project and run Reflection.
4. Use the Multi-Language Editor and Link Architecture View of SCS Manager to create and modify POUs for the safety application.
5. Create applications other than the application logic and generate the databases to download to SCS.
6. Examine the created application by using Safety Analyzer.

SEE ALSO For more information about details on how to create an application logic, refer to:

A., “Configuring application” in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

Creating a communication I/O list for a subsystem communication module

For SCS projects created in R4.01 to R4.03.00, you must enable the setting items of the subsystem communication modules to be handled in a safety communication I/O list.



SEE ALSO For more information about how to create a safety communication I/O list, refer to:

“■ Communication I/O List Output Tool” on page App.3-16

Engineering for fire and gas communication modules

Engineering for fire and gas communication modules can be implemented with I/O list engineering only.

Fire and gas communication modules are used for safety communication with Gas Detector GS01 from GasSecure AS. The following figure shows an example of device configuration.

*1: For fire and gas communication, PROFINET is used as the field network between SCS and YFGW410 and ISA100.11.a as the field wireless network. In addition, the PROFIsafe protocol is used for the safety layer of fire and gas communication.

Figure C2.1-3 Example of system configuration using fire and gas communication modules

Fire and gas communication modules can be defined with Safety Communication I/O Editor and used in SCS projects of SCSP3.

Overall flow of engineering for fire and gas communication

The following figure shows the flow of engineering for fire and gas communication.

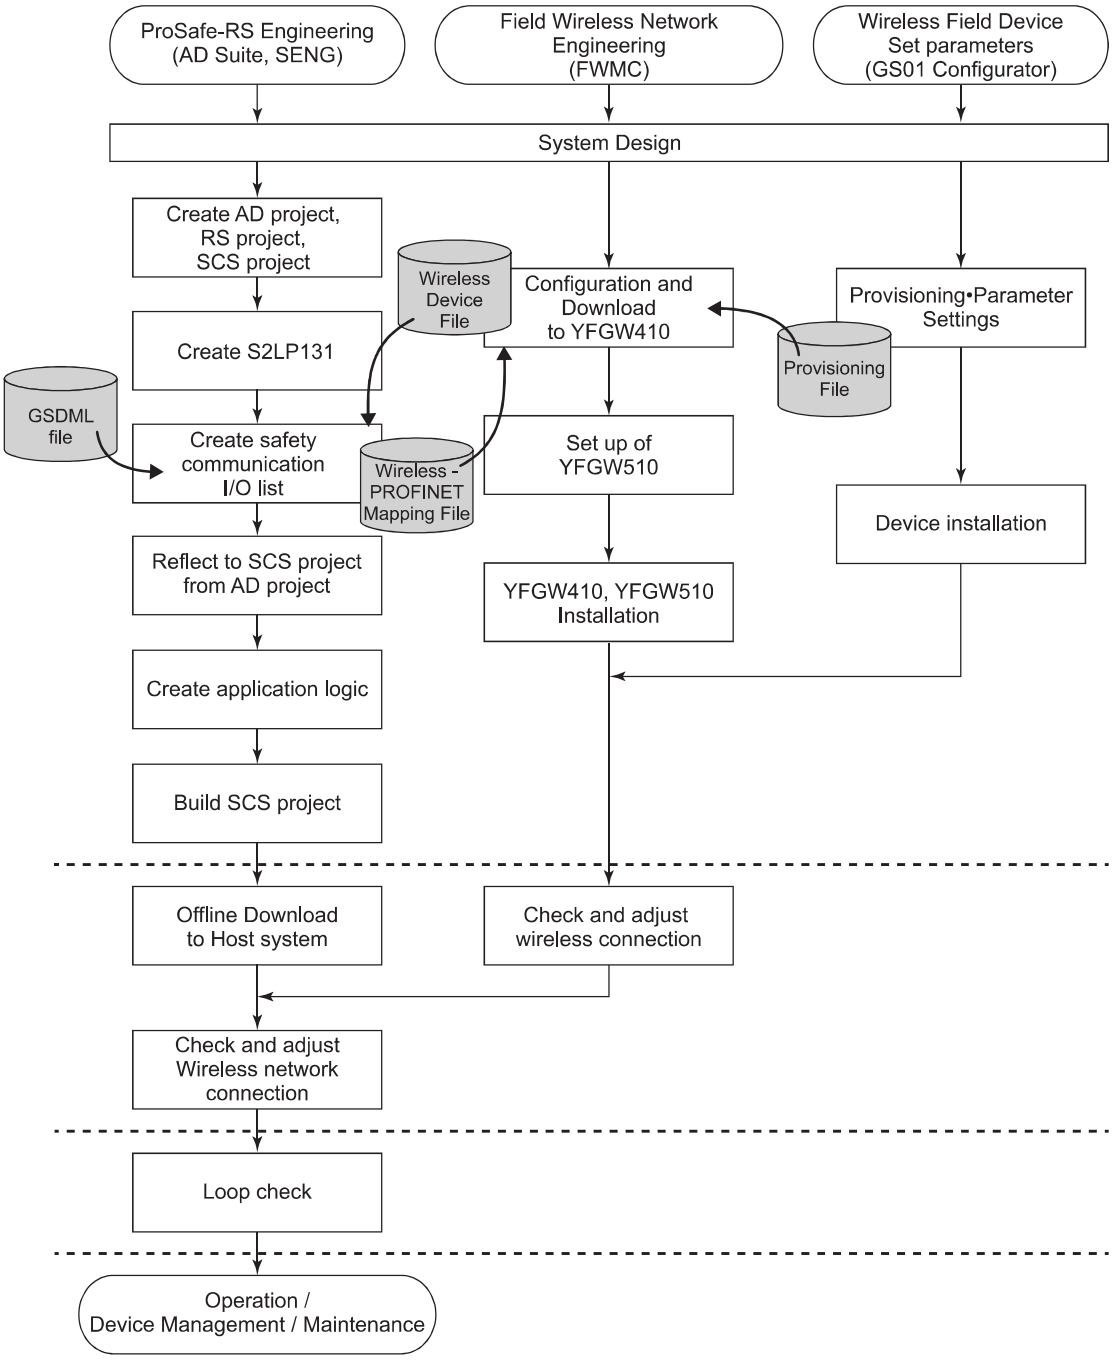


Figure C2.1-4 Flow of engineering for fire and gas communication

The following engineering is required to build a system for fire and gas communication:

- Engineering for SCS
- Engineering for a field wireless network
- Engineering for wireless field devices

SEE ALSO For more information about details of ProSafe-RS engineering, refer to:

E1.5, “Engineering for fire and gas communication” in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

C2.2 Work flow of I/O list engineering with iDefine

In the case of I/O list engineering, you can use iDefine for part of the engineering and testing process. This section explains the following important points for using iDefine:

- System configurations of ProSafe-RS and iDefine
- ProSafe-RS engineering functions and iDefine interface
- Engineering flow when using iDefine

IMPORTANT

When using ProSafe-RS and iDefine, use ProSafe-RS R4.02 to R4.08.

If you want to use SENG to edit engineering data created with iDefine, contact YOKOGAWA.

C2.2.1 System configuration when using iDefine

When using iDefine in ProSafe-RS, you can install ProSafe-RS (AD Organizer and SENG) and iDefine on the same computer or on separate computers.

The following figure shows an example of the system configurations when ProSafe-RS and iDefine are installed on the same computer.

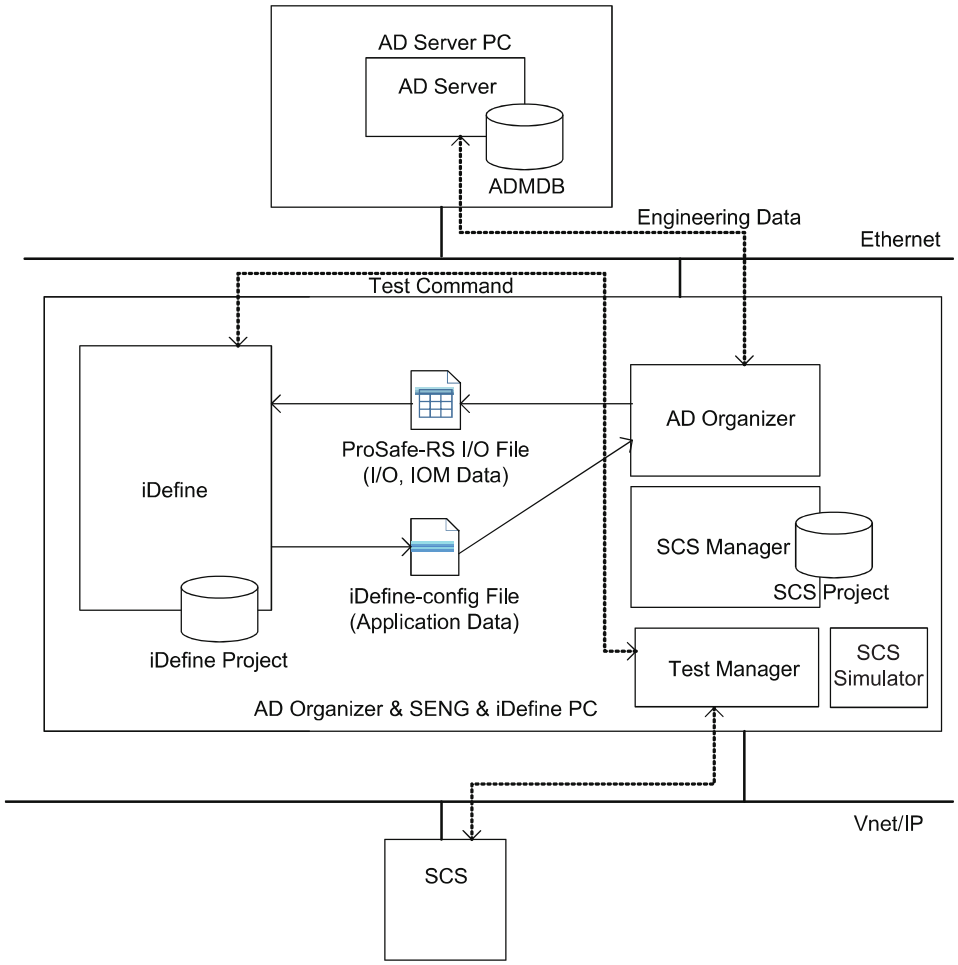

Figure C2.2.1-1 System configurations of ProSafe-RS and iDefine

C2.2.2 Relationship between ProSafe-RS engineering functions and iDefine

The following describes the relationship between ProSafe-RS engineering functions and iDefine when using iDefine.

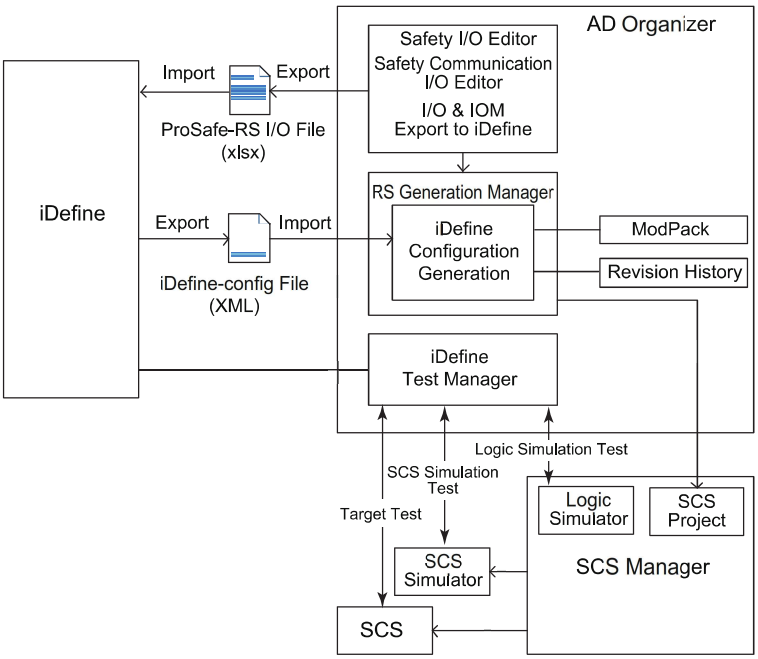

Figure C2.2.2-1 Relationship between ProSafe-RS engineering functions and iDefine

iDefine is used in the following ways in the application creation phase:

- iDefine can manage the data from multiple SCS projects. The engineer should decide how best to manage and associate iDefine projects with ProSafe-RS projects.
- The IOM definition, safety I/O list, and safety communication I/O list are managed in AD Suite and exported for iDefine as a ProSafe-RS I/O file in the xlsx format.
- The user creates an application in iDefine. Using information on the I/O of SCS, the ProSafe-RS I/O file that was generated from AD Organizer is imported and put to use. Engineering results are written as iDefine-config files in XML format for each SCS.
- The iDefine-config files that were generated are imported to AD Suite and reflected in SCS projects.

IMPORTANT

When starting iDefine from AD Organizer, there is no need to export the ProSafe-RS I/O file manually. You can import the I/O and IOM definitions of AD Organizer directly in iDefine. The iDefine-config file is imported directly from iDefine to AD Organizer.

- Data created by using iDefine such as POU and variables become read-only after it is reflected in SCS Manager.
- The run sequence of the POUs that were created by using the Multi-Language Editor can be changed in the Multi-Language Editor. The run sequence of the POUs that were created by using iDefine can be changed in iDefine.
- iDefine-config files can be assigned to ModPack in AD Suite. The history of iDefine-config files is also managed.

Logic simulation tests, SCS simulation tests, and target tests can be run from the iDefine test function.

- Launch iDefine Test Manager in AD Suite.
- iDefine can be connected with the logic simulator and SCS simulator of SCS Manager, and the actual SCS through iDefine Test Manager.
- Tests can be run using the iDefine test function.

Interface between ProSafe-RS and iDefine

ProSafe-RS I/O file and iDefine-config file serve as the interface between ProSafe-RS and iDefine.

- ProSafe-RS I/O file
  It includes information on the safety I/O list, safety communication I/O list, and I/O modules that are saved in ADMDB.

  The following items must be configured in the safety I/O list:

  - P&ID Tag
  - I/O Type (AI, AO, DI, DO)
  - I/O Tag
  - Signal Type
  - P&ID Group

  The following items must be configured in the safety communication I/O list:

  - P&ID Tag
  - I/O Type (AI, AO, DI, DO)
  - Signal Protocol
  - I/O Tag
  - P&ID Group

  If a value has been entered in the column for iDefine reference, such as Typical, in Safety I/O Editor and Safety Communication I/O Editor, you can view the value for reference purposes in iDefine.

  The safety I/O parameter profile defined in AD Organizer can be used as the I/O Parameter Profile of iDefine.

  Data that is checked-in to the AD Server is exported.

  The file is in the xlsx format with five worksheets.

  The following table shows the relationship between each worksheet and each iDefine editor.

Table C2.2.2-1 Relationship between the worksheets in ProSafe-RS I/O file and iDefine editors

Worksheet	iDefine editor
CIO worksheet	Client IO Table
IO worksheet	Client IO Table
IO Parameter worksheet	ProSafe-RS IO Parameter
Node worksheet	ProSafe-RS IO Node
IOM worksheet	ProSafe-RS IO Module

The content defined with Safety I/O Editor is not exported to the CIO worksheet.

The content defined with Safety Communication I/O Editor is not exported to the IO worksheet and the IO Parameter worksheet.

The following table shows the conditions for reflecting the data that is managed in AD Suite in each worksheet in the ProSafe-RS I/O file based on the rules for assigning information.

Table C2.2.2-2 Conditions for definitions of Safety I/O Editor being reflected onto the ProSafe-RS I/O file

Definition status of the I/O signal	Worksheet in the ProSafe-RS I/O file	Are definitions reflected onto the worksheet?
The I/O module to which the I/O signal is to be assigned is determined and the node to which the I/O module is to be assigned is already defined in IOM Definition Editor. However, the I/O module is not defined in IOM Definition Editor.	IO worksheet	Yes
	IO Parameter worksheet	Yes
	Node worksheet	Yes
	IOM worksheet	No
The I/O module to which the I/O signal is to be assigned is determined. However, the node to which the I/O module is to be assigned is not defined in IOM Definition Editor.	IO worksheet	Yes
	IO Parameter worksheet	Yes
	Node worksheet	No
	IOM worksheet	No
The I/O module to which the I/O signal is to be assigned is not determined yet. For example, one of the following columns in Safety I/O Editor is empty: • RS Project • SCS • Node Type • Node • IOM Category • IOM Type • Unit (For N-IO) • Slot • Terminal	IO worksheet	Yes
	IO Parameter worksheet	Yes (*1)
	Node worksheet	No
	IOM worksheet	No
The I/O Tag is not defined in the I/O signal.	IO worksheet	No
	IO Parameter worksheet	No
	Node worksheet	No
	IOM worksheet	No

*1: When a value has been entered for IOM Type

Table C2.2.2-3 Conditions for definitions of Safety Communication I/O Editor being reflected onto the ProSafe-RS I/O file

Definition status of the I/O signal	Corresponding worksheet	I/O signal definitions reflected?
The communication I/O module to which the communication I/O signal is to be assigned is determined and the node to which the communication module is to be assigned is already defined in IOM Definition Editor. However, the communication module is not defined in IOM Definition Editor.	CIO worksheet	Yes
	Node worksheet	Yes
	IOM worksheet	No

Continues on the next page

Table C2.2.2-3 Conditions for definitions of Safety Communication I/O Editor being reflected onto the ProSafe-RS I/O file (Table continued)

Definition status of the I/O signal	Corresponding worksheet	I/O signal definitions reflected?
The I/O Tag is defined in the communication I/O signal and the communication module to which the communication I/O signal is to be assigned is determined. However, the node to which the communication module is to be assigned is not defined in IOM Definition Editor.	CIO worksheet	Yes
	Node worksheet	No
	IOM worksheet	No
The I/O Tag is not defined in the communication I/O signal.	CIO worksheet	No
	Node worksheet	No
	IOM worksheet	No

- iDefine-config file
  This includes the POU, defined words, internal variables, FB instances, tag names, and parameters that were created by using iDefine.

  The file is in XML format.

SEE ALSO For more information about columns for iDefine reference, refer to:

"■ Setting items of the Safety I/O Editor" on page D1-7

■ Data from iDefine that is reflected in SCS Manager

When you import the iDefine-config file exported from iDefine into AD Organizer and run Reflection from RS Generation Manager, the data is reflected in the SCS Manager view and builders.

Table C2.2.2-4 Where data included in the iDefine-config file is reflected

Data in the iDefine-config file	Destination
POU	Link Architecture View
Internal variables and user defined FB instances (*1)	Dictionary View
Defined words	Dictionary View
Tag names and parameter	Tag Name Builder (*2)

*1: I/O variables and communication FB instances are not generated by iDefine. These are generated based on definitions of AD Organizer. The variables for instances of subsystem communication I/O FB can be defined with Safety Communication I/O Editor.
*2: It is reflected only when the CENTUM VP Integration Package or the CI Server Integration Package is enabled.

■ Selecting a FB with an instance name

From the function blocks that were defined in the POU that was created by using iDefine, you can select according to the type, the function blocks with instance name after imported to the SCS project. Select a function block with an instance name before you run Build All in iDefine. If you are starting iDefine directly, you can also select a function block with an instance name when importing the iDefine-config file to AD Organizer.

C2.2.3 Engineering by using iDefine

Applications can be created in iDefine by using the I/O list engineering method. The following methods are available for engineering by using iDefine depending on how iDefine is started:

- Starting iDefine from AD Organizer
- Starting iDefine directly

If you start iDefine from AD Organizer, operations between AD Organizer and iDefine are automated, and you can operate with reduced steps, for example, you do not have to start or switch tools, or check in.

If you start iDefine directly, you must import, export, and check in files, as well as start and switch tools.

This section describes the operation flow depending on how iDefine is started and details on the engineering method for iDefine, including AD Suite.

Refer to the following if you want to confirm the operation flow depending on how iDefine is started:

- Operation flow when starting iDefine from AD Organizer
- Operation flow when starting iDefine directly

Refer to the following if you want to confirm the details on the engineering method for iDefine, including AD Suite:

- Engineering flow when using iDefine

Engineering flow when using iDefine

The engineering flows when using iDefine are described in each of the following flows:

- Work flow from the start of engineering until the end of Typical test
- Work flow for engineering and testing the POU and I/O data of the SCS

Work flow from the start of engineering until the end of Typical test

iDefine breaks into parts the typical logic, such as the common input and output processes of application logics, and registers them as a template in Typical. Unit tests can be run on registered Typicals by using the emulator on iDefine, but sometimes the test function in SCS Manager is also used for testing to prevent engineering regression. However, it is possible that the specification for the application logic and I/O definition have not been finalized at this stage. In such a case, you need to configure a dummy I/O and logic, which is the bare minimum required to run a Typical test. The following figure explains the tasks that need to be done in SCS Manager, AD Suite, and iDefine in order to run a Typical test by using SCS.

*1: Data that is required to test Typical is included, as well as a tentative safety I/O list
*2: Operations that run automatically if you install AD Suite and iDefine on the same computer and start iDefine from AD Organizer.

C2.3 Work flow for RS original engineering

The following figure shows the engineering flow from the creation of an RS project and SCS project to the backing up of the projects (check-in) after completion in RS original engineering.

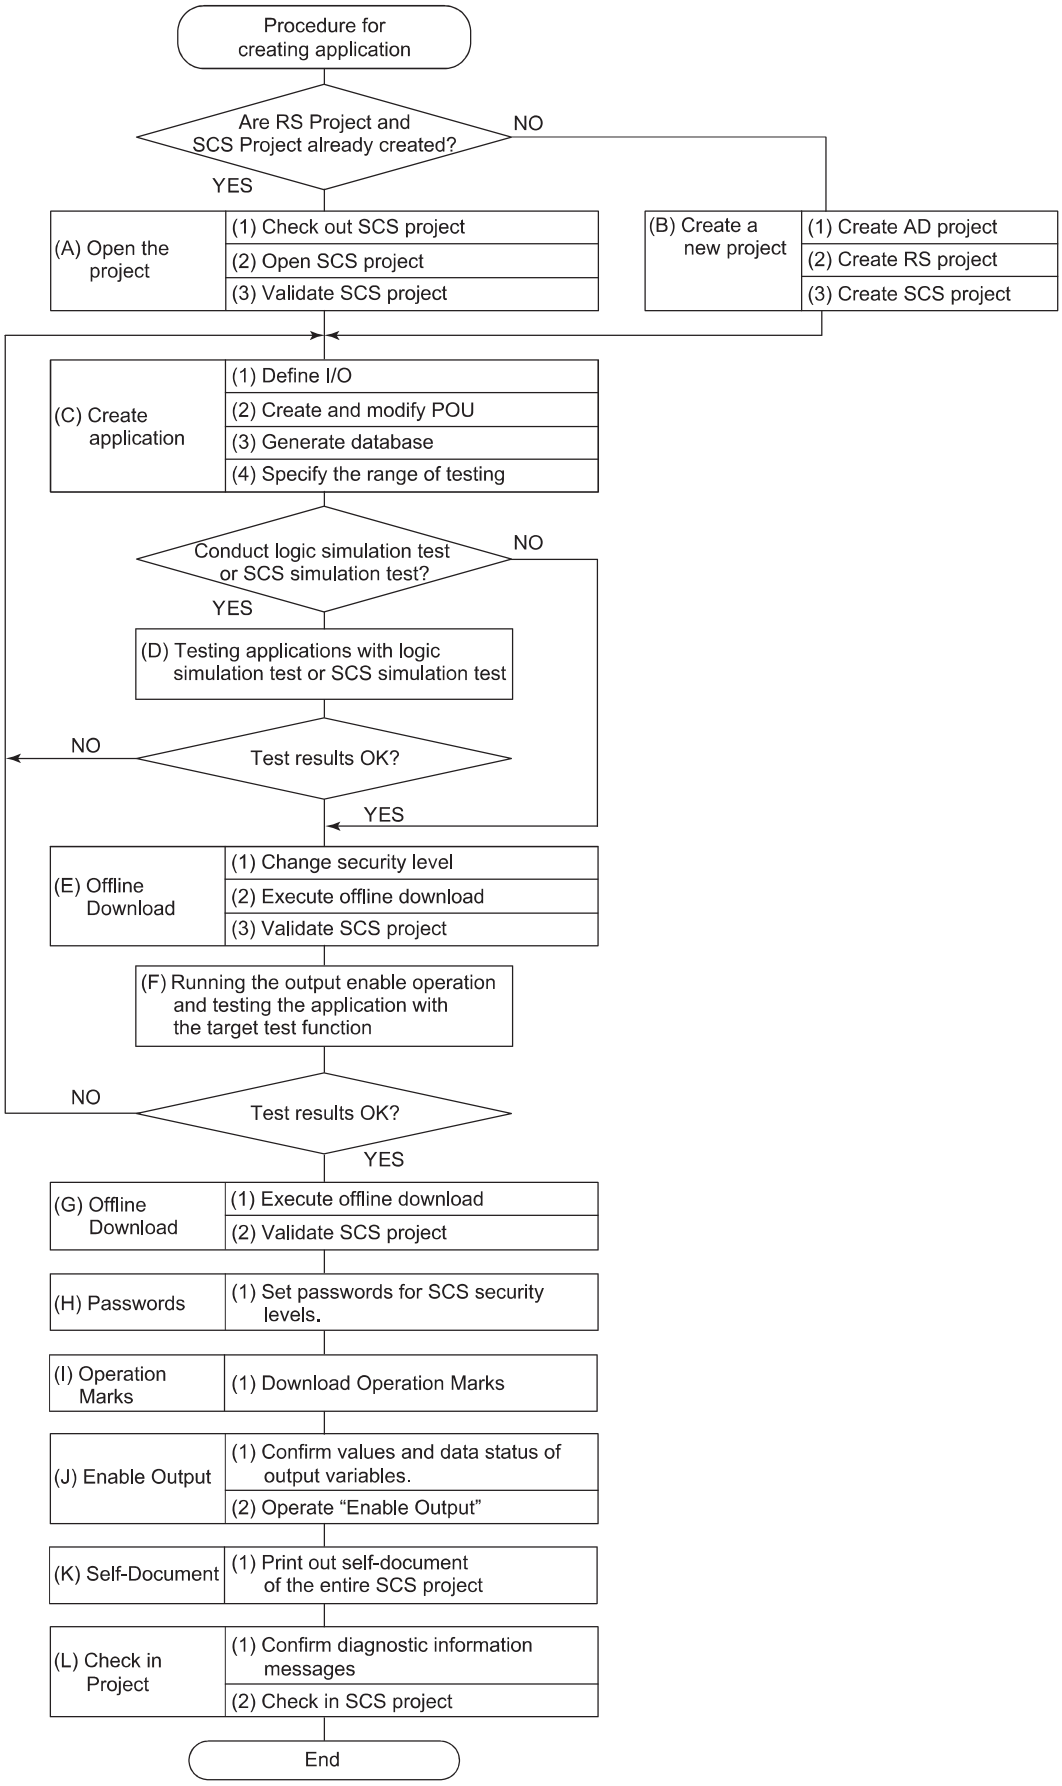

Figure C2.3-1 Procedure of creating an application

Detailed procedure for creating a new application

(A) Opening the project

Table C2.3-1 Procedure for opening the project

Item	Description
(1) Check out SCS project	• When check-in is performed by temporarily discontinuing on-going creation of an application, you can check out the created SCS project by using the Version Control Tool.
(2) Open SCS project	• Launch the SCS Manager. • Open the SCS project. • Enter the password for the SCS project.
(3) Validate SCS project	• Run the Database Validity Check Tool and check that the CRC codes and generation times of the databases are consistent between the SCS and SCS project. • Repair a database if there is a discrepancy in the database.

(B) Creating a new project

Table C2.3-2 Procedure for creating a new project

Items	Description
(1) Create an AD project	Perform the following tasks by using the ADS Administration Tool: • Set the ADMDB location • Create an AD project
(2) Create an RS project	• Only one folder of RS project is automatically created when the engineering function is installed. You need to set the folder of the RS project as a shared folder. • Then you can use AD Organizer to register the RS project in the AD project.
(3) Create an SCS project	To create a new SCS project, you need to configure the following settings by using SCS Manager: • Folder for SCS project • Properties of SCS project • Resource • Configuration • IP address

(C) Creating an application

Table C2.3-3 Procedure for creating an application

Items	Description
(1) Define Input/Output	• Define I/O variables.(Dictionary View) • Define I/O modules.(I/O Wiring View) • Perform wiring of channels and I/O variables (I/O Wiring View). • Set parameters for nodes, I/O modules and channels.(I/O Parameter Builder)
(2) Create and modify POU	• Open POU which you want to create and modify. • Edit POU. • Save POU. • Print POU. • Confirm that the logic entered in Multi-Language Editor is the same as the logic printed by using the self-document function. • Confirm that the execution order of FB/FU is correct.
(3) Generate database	• Perform build. • Analyze and confirm that the safety applications such as FU/FB are correct in terms of safety by using the Integrity Analyzer.

Continues on the next page

Table C2.3-3 Procedure for creating an application (Table continued)

Items	Description
(4) Specify the range of testing	• Run the Cross Reference Analyzer to check the changed Program Organization Unit (POU) and the affected POU and then authorize them. Then, visually check the following setting items, which are critical for safety, to be sure that there are no unintended changes, because changes in these items cannot be detected by the Cross Reference Analyzer. [Cycle Timing] in Resource Properties of SCS Manager Items in SCS Constants Builder: • [Optical ESB Bus Repeater] (for SCSP1/SCSV1) • [Maximum Extension Distance] (for SCSP1/SCSV1) • [Extend Scan Period Automatically] • [Behavior at Abnormal Calculation] • [Automatic IOM Download] • [Locking of Internal Variables] (for SCSP3/SCSL2/SCSP2) • [Device Power-Off Period] (for SCSP3/SCSL2/SCSP2/SCSP1/SCSU1) • [Device Startup Waiting Period] (for SCSP3/SCSL2/SCSP2/SCSP1/SCSU1) • [Skip Password Dialog Box for Manual Operation FB] (for SCSP3/SCSL2/SCSP2/SCSP1)

SEE ALSO For more information about Integrity Analyzer, refer to:

C5.1, “Integrity Analyzer” on page C5-2

For more information about Cross Reference Analyzer details, refer to:

C5.2, “Cross Reference Analyzer” on page C5-19

(D) Testing the application with the SCS simulation test or Logic simulation test function

Test the user application by using the SCS simulation test or logic simulation test.

SEE ALSO For more information about details of SCS simulation test and logic simulation test, refer to:

C6., “Simulation tests” on page C6-1

(E) Offline download

Table C2.3-4 Procedure for offline download

Items	Description
(1) Change Security Level	• Start the SCS Maintenance Support Tool which monitors the SCS from the SCS Manager. • Set the SCS security level to 0. Entering a password is required. • Confirm that the SCS Security Level is 0 on the SCS State Management window of the SCS Maintenance Support Tool. • Confirm the diagnostic information message indicating the security level at 0 with the SCS Maintenance Support Tool.
(2) Execute Offline Download	• Execute offline download. • When integrated with CENTUM, choosing offline downloading menu will pop up a dialog box to prompt for saving the operation marks. The operation marks may be saved as necessary. • Confirm that SCS has started normally on the SCS State Management window of the SCS Maintenance Support Tool.
(3) Validate SCS project	• Start the Database Validity Check Tool to check that CRC and generation time of four kinds of databases for SCS and SCS project are correct. • Repair a database if there is a discrepancy in the database.

SEE ALSO For more information about offline download operations, refer to:

"■ Procedure for offline download" on page C7-2

For more information about repairing a database, refer to:

"■ Repair database" in F3., "Database Validity Check Tool" in Engineer's Reference Manual (IM 32P04B10-01EN)

(F) Target tests

Perform the output enable operation and test the user application on the target SCS.

SEE ALSO For more information about details of target test, refer to:

C9., "Target tests" on page C9-1

(G) Offline download

Table C2.3-5 Procedure for offline download

Items	Description
(1) Execute Clean Project and Build	• Before you execute offline download, you should perform Clean Project. Then perform build to create the database for downloading.
(2) Execute Offline Download	• Execute offline download. • When integrated with CENTUM, choosing offline downloading menu will pop up a dialog box to prompt for saving the operation marks. Save the operation marks as necessary. • Confirm that SCS has started normally on the SCS State Management window of SCS Maintenance Support Tool.
(3) Validate SCS project	• Run the Database Validity Check Tool and check that the CRC codes and generation times of the databases are consistent between the SCS and SCS project. • Repair a database if there is a discrepancy in the database.

SEE ALSO For more information about clean project, refer to:

Cleaning Projects" in "Build" in "Code Generator" in "Workbench" in the Workbench User's Guide

(H) Setting passwords

Table C2.3-6 Procedure for setting passwords

Items	Description
Set passwords for Security Levels	• Set passwords for security levels 1 and 0 from the SCS Manager. • Confirm the diagnostic information message from SCS for which passwords for the security levels have been set with the SCS Maintenance Support Tool.

(I) Download operation marks

Table C2.3-7 Procedure for downloading operation marks

Items	Description
Download Operation Marks	• In the case of the CENTUM integration structure, the operation marks saved in advance are downloaded to the SCS.

(J) Enabling output

Table C2.3-8 Procedure for enabling output

Items	Description
(1) Confirm values and data status of output variables	• Confirm which output channels are disabled on the SCS State Management window of SCS Maintenance Support Tool. • Start the I/O Lock Window.(This can be performed at security level 2.) • Confirm that values and statuses of logical data and physical data for output variables are correct.
(2) Operate “Enable Output”	• Perform the Output Enable Operation for output modules on the SCS State Management window of SCS Maintenance Support Tool. • Confirm that the diagnostic information message on the Output Enable Operation for output modules is displayed. • Confirm that Output Channels are enabled on the SCS State Management window. • Confirm that the SCS operating mode is "Running" on the SCS State Management window.

SEE ALSO For more information about Output enable operation details, refer to:

“■ Enable Output operation” on page C8-2

(K) Self-document

Table C2.3-9 Procedure for self-document

Items	Description
(1) Print out whole SCS project using self-document	• In preparation for the desk check performed at application software changes in the future, print out the latest SCS project database as self-documents.

(L) Checking in project

Table C2.3-10 Procedure for checking in a project

Items	Description
(1) Confirm the diagnostic information message	• Confirm whether any diagnostic information messages you have not confirmed are displayed or not with the SCS Maintenance Support Tool.
(2) Check in SCS project	• Close the SCS Manager. • Check in the SCS project with the Version Control Tool.

SEE ALSO For more information about check-in operations, refer to:

F5.3, “Checking in project data” in Engineer's Reference Manual (IM 32P04B10-01EN)

C3. Precautions when creating applications

The tools and builders that can be used to define variables, POU, tag names are not the same due to differences in the engineering method. This section explains the precautions for handling them.

Precautions for handling variables in I/O list engineering

In the case of I/O list engineering, the variables can be defined by using Safety I/O Editor, Safety Communication I/O Editor, and SCS Manager. Variables defined by using other tools are read-only. iDefine can also be used to define variables if you are using the tool.

The differences are as follows:

- Safety I/O Editor
  This is used to define I/O variables.
- Safety Communication I/O Editor
  The following can be defined:
  - Instances of subsystem communication I/O FB
  - Instances of PROFINET communication FB
  - Instances of fire and gas communication FB

  In addition, the following variables can be assigned to the communication I/O data area:
  - FB instances defined with Safety Communication I/O Editor
  - Local FB instances defined with SCS Manager
  - FB instances of user defined FB parameters defined with SCS Manager or iDefine

  The communication I/O data area is shown in Communication I/O Builder on the Comm. I/O Wiring tab or Safety Comm. I/O Wiring tab.
- iDefine
  This is used to define internal variables and FB instances.
- SCS Manager
  This is used to define internal variables and FB instances.

Precautions for handling POU

- Handling POU when using iDefine
  You can create POU by using iDefine or the Multi-Language Editor. However, POUs that were created by using iDefine are read-only in Multi-Language Editor. POUs that were created by using the Multi-Language Editor can only be changed in the Multi-Language Editor. However, if you create a POU by using iDefine with the same name as a POU that is already registered in the Link Architecture View, you can overwrite the existing POU with confirmation when you run Reflection in RS Generation Manager.

Precautions for handling tag names

You can define tag names by using iDefine or the Tag Name Builder. Tag names that were defined by using iDefine are read-only in the Tag Name Builder. Tag names that were defined by using iDefine can only be changed in iDefine. Tag names that were defined by using the Tag Name Builder can only be changed in the Tag Name Builder.

Precautions on communication I/O definitions

When performing I/O list engineering with a version of SENG that is R4.03.10 or later, engineering for subsystem communication and safety subsystem communication is all implemented with Safety Communication I/O Editor and IOM Definition Editor of AD Organizer. Communication I/O Builder will be used as read-only. Engineering for Modbus slave communication and the DNP3 slave function is implemented with SCS Manager.

When reusing engineering data related to subsystem communication I/O created with version earlier than R4.03.10, convert the data into a safety communication I/O list by using Communication I/O List Output Tool.

SEE ALSO For more information about communication I/O List Output Tool, refer to:

"■ Communication I/O List Output Tool" on page App.3-16

Precautions for handling an SCS project that was checked in with Version Control Tool of a revision earlier than R4.03.10

When you check out an SCS project that was checked in with Version Control Tool of a revision earlier than R4.03.10 and is handled by I/O list engineering, perform the task of restoring the safety I/O list and IOM information within AD Organizer to the content labeled at the time of the previous download.

Precautions for restoring an SCS project that was generated by RS generation with AD Organizer of a revision earlier than R4.03.10

If you have used Master Database Restoring Function to restore an SCS project that was generated by RS generation with AD Organizer of a version earlier than R4.03.10 and downloaded to the SCS, you must also restore the safety I/O list and IOM information to the correct contents. By using AD Organizer, recover the safety I/O list and IOM information that are labeled at the time of downloading last time.

Precautions for managing SCS projects in AD Server

SCS projects are managed in an AD Server. The following describes the precautions for handling SCS projects:

- Creation of new SCS projects
  The selection of station type and I/O list engineering method should be determined at the time of SCS project creation, and cannot be changed afterwards.
- Deleting SCS projects
  To delete an SCS project, you must clear all items under the SCS project folder by using Windows Explorer. After that, delete the SCS project by using AD Organizer.
- Moving SCS projects
  For SCS projects registered in AD Server, you need to move the SCS projects by using the export/import function of AD Organizer. In the destination folder, do not duplicate the SCS project name and station address. Do not move the SCS project in Windows Explorer.
- Modification of SCS project names
  You need to use the SCS project export/import function of AD Organizer. You need to specify a new SCS project name at the time of importing. Do not rename the SCS project in Windows Explorer.
- Backup of SCS projects and RS projects
  You need to use the backup function of AD Organizer. You cannot run backup from Windows Explorer.

- Test Project Creating Tool
  In the case of SCS projects created with I/O list engineering, the safety I/O list, safety communication I/O list, and IOM information are registered in AD Organizer, while various setting files are included in SCS projects managed by SCS Manager.

  In case of creating a test project from the current project, you need to create a separate AD project for testing.

- License management
  You can check whether the I/O number has exceeded the number of I/O licenses by using the SCS information display function.

  If a module is added, you need to confirm the license count at the time of RS generation

C4. Procedures for generating a database

After creating the application, generate a database. This chapter describes the steps for generating a database.

Generating a database

After creating the application, build it and generate a database for SCS.

- Generating a database in I/O list engineering
  In the case of I/O list engineering, run RS generation from AD Organizer. The reflection process of RS generation reflects the engineering result of AD Organizer in SCS Manager. If you have specified the build, after the reflection process has been completed successfully, the application is built and the database is generated.

  When an SCS project for which I/O list engineering is selected has been built successfully, labels are set to the safety I/O list, safety communication I/O list, and IOM information of AD Suite. Label names are as follows:

  ```
  SCS project name-Build-Time
  ```

- Generating a database in I/O list engineering with iDefine
  Import the relevant SCS iDefine-config file that was generated from iDefine into AD Organizer and perform RS generation. To adjust the POU run sequence, run the reflection process only, change the sequence by using the Link Architecture View, and build by using SCS Manager. If you do not adjust the POU run sequence, run the build process for SCS projects by using RS Generation Manager.
- Generating a database from SCS Manager
  From the menu bar of SCS Manager, click [Project] > [Build Project], or run build project from the tool bar of SCS Manager. This method is used to build and generate a database in the case of RS original engineering. The message from database creation function appears in SCS Manager.

C5. Testing with the Safety Analyzers

The following tools are provided for the purpose of analyzing application logic.

- Integrity Analyzer
- Cross Reference Analyzer

Integrity Analyzer is used to analyze application logics and detect functions whose use is not permitted in terms of safety. If unauthorized functions are used, operations for acknowledging the use are required.

Cross Reference Analyzer is used to analyze areas affected by modifications and display the test area when the application logic is modified. It is required to perform acknowledgement operation for this test area.

IMPORTANT

Make sure to perform the acknowledgement operations for both analyzers before downloading the application logic to an SCS. If acknowledgement by both analyzers has not been completed, offline download and online change download to SCS cannot be performed.

It is recommended to perform the acknowledgement operation with Integrity Analyzer first and then with Cross Reference Analyzer.

C5.1 Integrity Analyzer

Integrity Analyzer analyzes application logics, detects "functions that are not allowed to be used" for the functions for safety and displays them in the window by highlighting for visual emphasis.

The user can check whether or not functions prohibited from use for safety applications are used. You can also print the analysis results.

If there is a program that intentionally makes use of functions prohibited from use for application, the user can acknowledge their use for each program upon examining the program based on the results of the analysis.

If functions prohibited from use for safety applications are used unintentionally, the application logic must be modified. Make changes to the application logic, perform a build operation and then analyze the application logic with Integrity Analyzer again.

IMPORTANT

- Before downloading application logic to SCS or before performing the SCS simulation test, run Integrity Analyzer and Cross Reference Analyzer, check and acknowledge the analysis results.
- It is possible to execute an application logic on a PC in logic simulation tests even if it has not been analyzed by both analyzers.
- Even when logic simulation tests are used, make sure to check that only functions whose use is permitted for safety applications and interference-free functions are used in an application logic by Integrity Analyzer at the appropriate time in order to detect errors in the application logic.

C5.1.1 Methods for checking analysis results

This section explains how to check results of analysis by Integrity Analyzer.

Starting Integrity Analyzer

1. After a build operation, select [Engineering] from the [Tools] menu of SCS Manager.
   The Engineering launcher menu appears.
2. Select [Integrity Analyzer] from the Engineering launcher menu.
   Integrity Analyzer starts up and analyzes the application logic in question.

IMPORTANT

- Start Integrity Analyzer after modifying and saving an application logic and performing a build operation. Integrity Analyzer analyzes the databases generated by the build operation.
- If Integrity Analyzer has already been started when you attempted to perform a build or download operation, a dialog box prompting to close Integrity Analyzer appears. In this case, neither the build nor the download operation is performed.

Procedure for using Integrity Analyzer

The procedure for using Integrity Analyzer is explained below.

1. Checking functions prohibited from use in terms of safety in Project Tree
   The results of analyzing the application logic with Integrity Analyzer are displayed in Project Tree. Check whether or not functions prohibited from use in terms of safety are used.
2. Checking with analysis result report
   Check the Integrity Analysis Report showing the analysis results, either directly in a window or by printing it out.
3. Acknowledgement of functions prohibited from use in terms of safety
   If there are programs that use interference-free functions intentionally, acknowledge the use of those functions for each program in the Acknowledge Non-Compliance dialog box upon examining the programs based on the analysis results.

   If interference-free functions are used unintentionally or prohibited functions are used, it is necessary to modify the application logic in question. Close Integrity Analyzer without approving the functions, modify the application logic, perform a build operation and then analyze the application logic by Integrity Analyzer again.
4. Saving and printing analysis results
   Save the analysis results and print them if necessary.

Checking functions prohibited from use in terms of safety in project tree

Project Tree allows checking whether or not functions that are prohibited from use in terms of safety exist in an application logic.

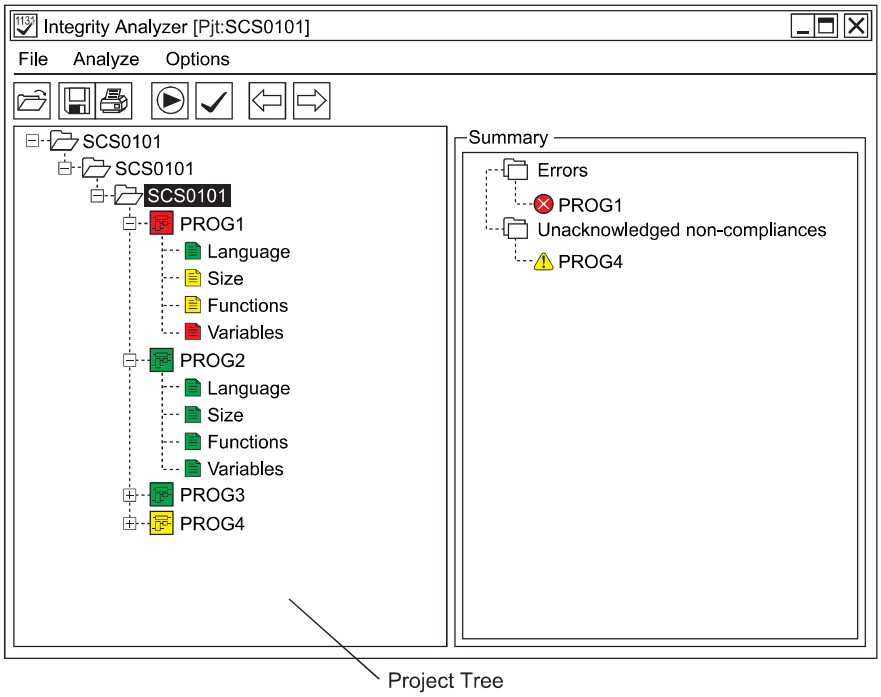

Figure C5.1.1-1 Project tree of Integrity Analyzer

The graphical analysis results can only be viewed in the window; it cannot be printed out.

How to understand icon colors

Project Tree displays SCS projects, configurations, resource and programs in a tree structure. Double-click a program icon to display icons for [Language], [Size], [Functions] and [Variables]. Analysis results are shown using colored icons placed to the left of the labels in the tree.

Table C5.1.1-1 Meaning of colors of icons on the left side of project tree

Icon color	Description
Red	Errors. Red icons indicate that prohibited functions are used. For example, using AND with 17 or more input parameters or using arrays in FBD or LD fall under this classification. It is necessary to modify programs for which red icons are displayed and remove the prohibited functions. It is not possible to download application logics to an SCS if they contain prohibited functions.
Yellow	Warnings. Yellow icons indicate that interference-free functions are used. For example, SIN and COS functions cannot be used in safety applications but can be used in other applications (control logics that do not influence safety). Check that the areas where the interference-free functions exist are outside the range of safety applications. Alternatively, check that there is no influence on safety applications. Once the use of interference-free functions is acknowledged, the applications can be downloaded to an SCS.
Green	No error. Green icons indicate that a program is created using only the functions for safety (safety applications are created). Though acknowledgement is not required, the acknowledgement status needs to be saved.

If you select an individual icon in Project Tree, detailed analysis information of items to be checked is displayed in the right pane of the window. The right pane shows analysis results of an item selected in Project Tree using one of the following icons.

Table C5.1.1-2 Meaning of icons in the right pane

Icon	Meaning
 (red)	Error. Prohibited functions are used.
 (yellow)	Warning. Interference-free functions are used.
 (green)	No error. A program is created using only the functions for safety.

SEE ALSO For more information about details on how to read the analysis results of the program in Project Tree, refer to:

C5.1.3, “Confirmation of analysis results by project tree” on page C5-12

Checking with Analysis report

The Integrity Analysis Report organizes and summarizes all the information in analysis results. It can be displayed in a window, printed or saved in a file (using RTF or TEXT format) as a report.

The Integrity Analysis Report is used mainly for the following two applications.

- It provides more detailed information than the information obtained by expanding Project Tree.
- The Integrity Analysis Report can be used as a part of operation records or application construction documentation, by printing it out or saving it to a file. The Integrity Analysis Report also includes information about whether or not acknowledgement is made in the Acknowledge Non-Compliance dialog box, along with comments. In order to record acknowledged items, print or save the report in a file after acknowledgement.

Figure C5.1.1-2 Example of Integrity Analysis report

Saving and displaying Analysis report

1. Select a resource in Project Tree and select [Save Analysis] from the [File] menu. Alternatively, click the [Save current analysis history] button in the toolbar.
   the analysis results are saved.
2. Select [Report] from the [Analyze] menu.
   The saved analysis results are displayed as an analysis report.

IMPORTANT

Make sure to save the analysis results before creating an analysis report.

If the current analysis results and acknowledgement history are not saved before creating an analysis report, a message prompting you to save the history is notified. If you click [Yes] button in the message box, the current analysis results and acknowledgement history are saved, overwriting the history saved before in the process, and an analysis report is created. An analysis report is not created if you click [No] button.

Acknowledgement of interference-free functions

If the analyzed application logic includes programs using interference-free functions, it is necessary to acknowledge such programs one by one in the Acknowledge Non-Compliance dialog box.

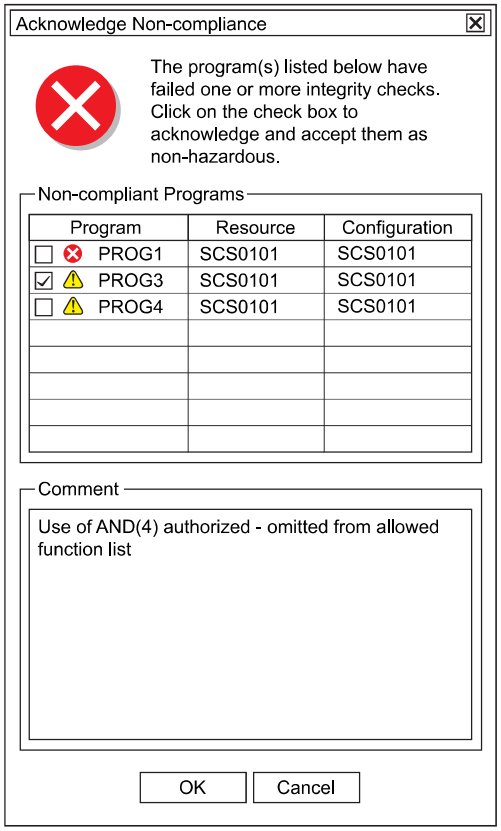

Figure C5.1.1-3 Acknowledge Non-compliance dialog box

Displaying the Acknowledge Non-compliance dialog box

Select [Authorize] in the [Analyze] menu. Alternatively, click "Display program non-compliance dialog" button in the toolbar. The Acknowledge Non-Compliance dialog box appears.

Acknowledgement of programs and displayed icons

This dialog box shows analysis results of each program with one of the following icons.

Table C5.1.1-3 Meaning of icons

Icon (color)	Description
 (red)	A program uses prohibited functions. This icon has the same meaning as the red program icon displayed in Project Tree. Modify the program and remove the prohibited functions. This program cannot be acknowledged.
 (yellow)	A program uses interference-free functions. This icon has the same meaning as the yellow program icon displayed in Project Tree. In order to download the programs to an SCS, it is necessary to check each check box of all the programs marked with this icon and acknowledge them.

Before approving, confirm that only the functions for safety are used in the safety application using Project Tree or by checking the Integrity Analysis Report.

The reasons why interference-free functions are used, results of analysis for the purpose of acknowledgement, etc., can be entered as comments. The Integrity Analysis Report includes information about whether or not acknowledgement was made along with any comments entered.

C5.1.2 Integrity Analyzer window structure

This section explains the window structure of Integrity Analyzer.

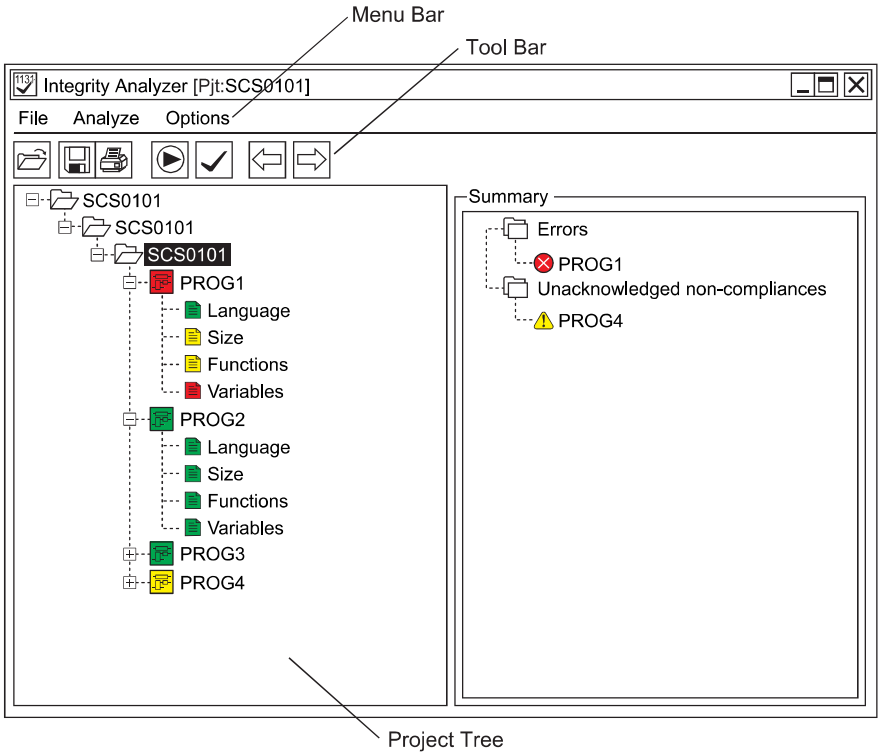

Figure C5.1.2-1 Integrity Analyzer window structure

Menu bar

The menu bar provides the following menus.

- [File] menu
- [Analyze] menu
- [Options] menu

The menu items of each menu are explained below.

Table C5.1.2-1 File menu

Menu item	Description
Print Report	Prints an analysis report saved by [Save Analysis]
Save Report	Creates an analysis report and saves it in a file (RTF or TEXT format)
Save Analysis	Saves analysis results and acknowledgement status.
Exit	Closes Integrity Analyzer

Table C5.1.2-2 Analyze menu

Menu item		Description
Start	With history	Performs analysis and compares with the results of previous warning acknowledgement and analysis. If the areas acknowledged in the previous analysis are not modified this time, it is regarded as if they have already been acknowledged.
	Without history	Performs analysis without comparing it with results of previous acknowledgement and analysis

Continues on the next page

Table C5.1.2-2 Analyze menu (Table continued)

Menu item	Description
Report	Creates and displays the analysis report in the Integrity Analysis Report window
Authorize	Displays the Acknowledge Non-Compliance dialog box.

Table C5.1.2-3 Options menu

Menu item	Description
Settings	Displays the Settings dialog box

IMPORTANT

Make sure to save the analysis results before creating an analysis report.

If the current analysis results and acknowledgement history are not saved before creating an analysis report, a message prompting you to save the history is notified. If you click [Yes] button in the message box, the current analysis results and acknowledgement history are saved, overwriting the history saved before in the process, and an analysis report is created. An analysis report is not created if you click [No] button.

Toolbar

The toolbar provides the following buttons.

Table C5.1.2-4 Toolbar buttons

Button	Name	Description
	Save current analysis history	Saves analysis results and acknowledgement status.
	Print report for a selected resource	Prints analysis reports.
	Display program non-compliance dialog	Displays the Acknowledge Non-Compliance dialog box.
	Previous non-compliance	Selects the icon of the previous interference-free element or element not allowed in terms of safety relative to the currently selected icon in Project Tree (the upward direction in the tree).
	Next non-compliance	Selects the icon of the next interference-free element or element not allowed in terms of safety in Project Tree relative to the currently selected icon (the downward direction in the tree).

Project tree

Project Tree is displayed on the left pane of the Integrity Analyzer window.

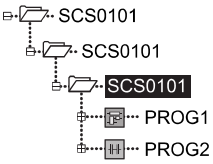

Figure C5.1.2-2 Project tree

Each level of Project Tree can be expanded or collapsed by double-clicking an icon or text label, or clicking the +/- button on the left edge.

Analysis results of an item selected in Project Tree are displayed in the right pane of the window.

The display arrangement of Project Tree can be defined in Settings dialog box.

Displaying the Settings dialog box

On the [Options] menu, click [Settings]. The Settings dialog box appears.

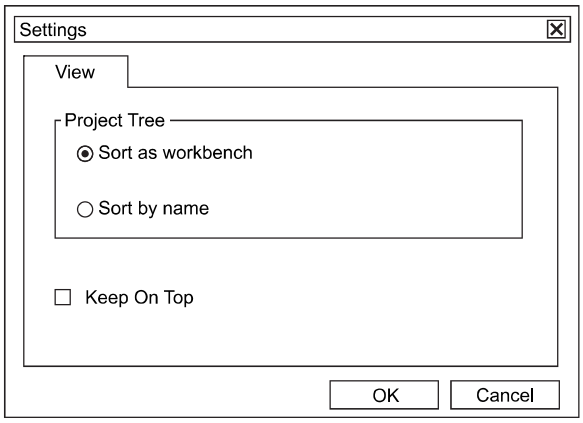

Figure C5.1.2-3 Settings dialog box

- Project Tree
  Sort as workbench: Contents displayed on Project Tree are sorted along with Workbench.

  Sort by name: Contents displayed on Project Tree are sorted by names alphabetically.
- Keep On Top
  Integrity Analyzer window is kept always on top.

C5.1.3 Confirmation of analysis results by project tree

This section explains how to understand the detailed information displayed when the following layers below the resource (the SCS project) are selected in Project Tree.

- Resource (list of program errors and unacknowledged warnings in a resource)
- Program (program classification and analysis results)
- Language (language usage information of a program)
- Size (size information of a program)
- Functions (results of analyzing program source code and object code)
- Variables (results of analyzing variables in a program)

Displaying analysis results of Functions and Function Blocks

Project Tree displays analysis results of FUs and FBs as part of the summary for the program that calls the FUs and FBs.

That is, if you expand an icon of a program name, not only the analysis results of the program itself, but also the analysis results for the FUs and FBs called by the program are displayed.

Checking resources

A list of analysis statuses of resources (SCS projects) is displayed in the right pane of the window. The list displays detected errors and unacknowledged warnings.

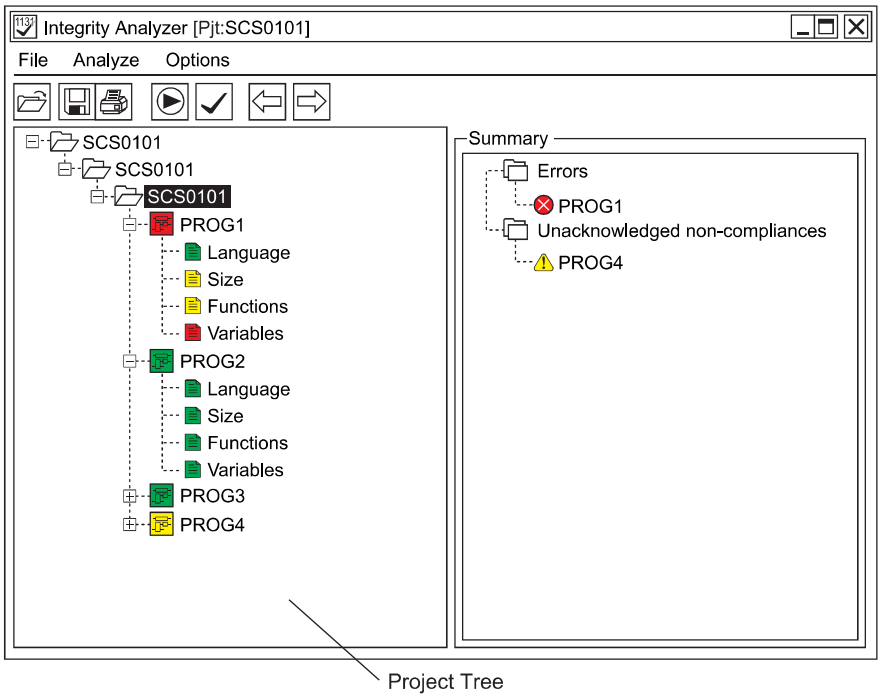

Figure C5.1.3-1 Analysis results of resource

The analysis results of the selected resource are classified into errors and unacknowledged warnings, and displayed in a tree structure in the right pane. Errors and unacknowledged warnings can be expanded or collapsed.

These graphical analysis results can only be viewed in the window; they cannot be printed out.

Checking programs

When you select a program name in Project Tree, a list of analysis results of the program is displayed in the right pane of the window. The classification of the program and the result of analysis (Pass, Fail, Warning) are displayed.

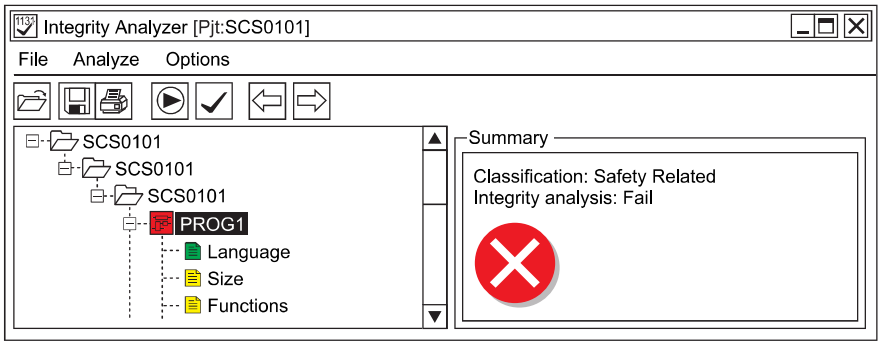

Figure C5.1.3-2 Analysis results of a program for which error occurred

These graphical analysis results can only be viewed in the window; they cannot be printed out.

Checking program languages

If you select [Language] in Project Tree, the language used for the program is displayed in the right pane of the window. If the program includes user-defined FUs or user-defined FBs, the languages used for them are shown as well.

Table C5.1.3-1 Icons displayed on the left side of program names and meaning

Icon (color)	Meaning
✓ (green)	POUs are created using permitted languages
✗ (red)	POUs are created using languages that are not allowed (*1)

*1: When using ST to write a program other than FU and FB, an error will occur.

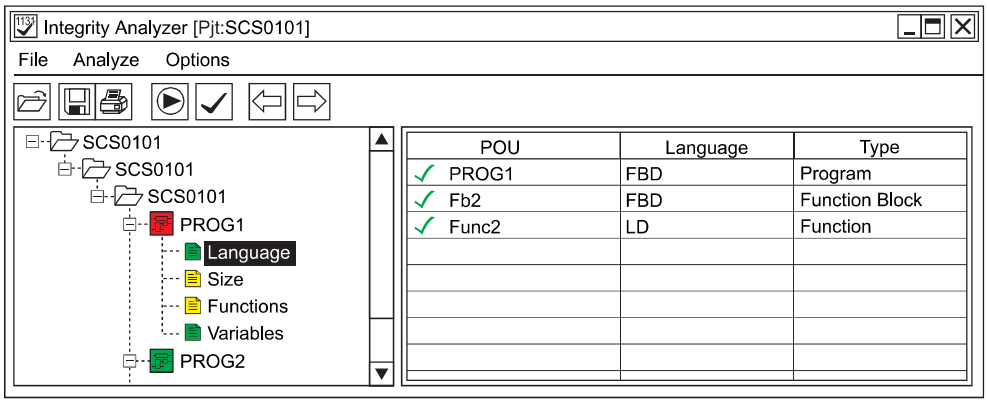

Figure C5.1.3-3 Results of checking languages used in programs

The screenshot example above shows the result of analyzing languages used in PROG1. PROG1 uses a function block called Fb2 and a function called Func2. PROG1, Fb2 and Func2 are written with permitted languages.

These graphical analysis results can only be viewed in the window; they cannot be printed out.

Checking program size

IMPORTANT

If the program size exceeds the specified limit, a warning is displayed. However, even if the warning is displayed, you can still use the program for a safety function after sufficiently confirming the validity of the program through some testing.

If you select [Size] in Project Tree, the size of the program and the specified upper limit size are displayed in the right pane of the window. If the program includes user-defined FUs or user-defined FBs, their program sizes are shown as well.

For the FB created with ST, the number of lines excluding the comment lines and blank lines as well as the maximum number of lines is displayed.

Table C5.1.3-2 Icon displayed on the left side of program names and meaning

Icon (color)	Meaning
⚠ (yellow)	The program size exceeded the warning range

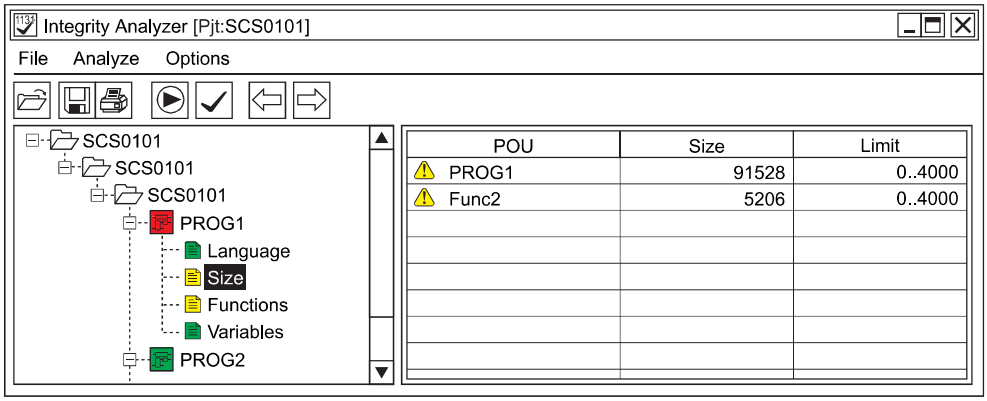

Figure C5.1.3-4 Program size information

These graphical analysis results can only be viewed in the window; they cannot be printed out.

Checking program source code and object code

If you select [Functions] in Project Tree, the results of analyzing the source code and object code of the program are displayed as a list of unauthorized FUs or FBs used in the right pane of the window.

An icon displayed to the left of a function name or function block name indicates that the FU or FB is not allowed in terms of safety.

Table C5.1.3-3 Icons displayed on the left side of Function names/Function Block names and meaning

Icon (color)	Meaning
⊗ (red)	The FU or FB in question is not classified as safe or interference-fee and its use caused an error
⚠ (yellow)	The FU or FB in question is classified as interference-free and its use in a safety program requires acknowledgement

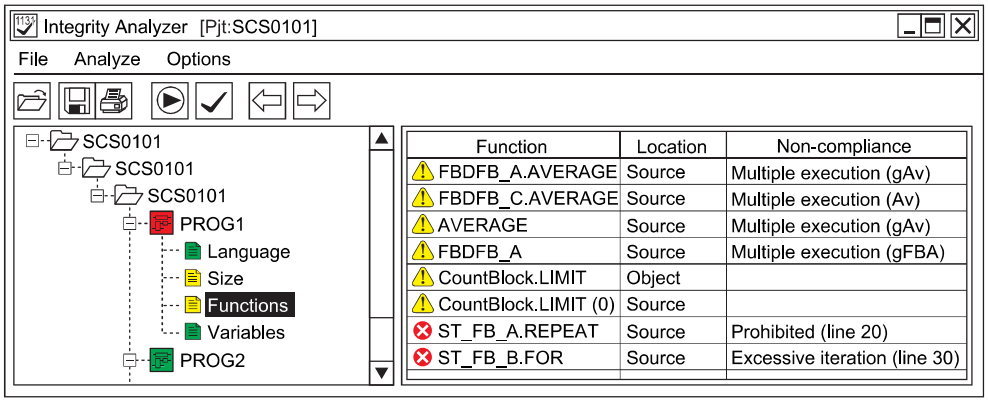

Figure C5.1.3-5 Information of Function usage in the program

Integrity Analyzer searches in one or multiple POUs for the functions calling the same FB instance and displays the functions as the analysis result. If the same FB instance in a POU is called by multiple functions from different locations, the related functions and POUs will be displayed with respective warning messages. The above figure illustrates the result of the analysis.

In the message displayed in the "Function" column of the preceding figure, FBDFB_A is the name of the POU and AVERAGE is the type of the FB. The instance name or parameter name is displayed in parentheses in the "Non-compliance" column.

In LD source code analysis, the existence and usage of EN inputs inside the program are also detected. An EN input refers to the first BOOL-type input that is automatically appended when the type of the first input for FUs or FBs is BOOL in LD.

If libraries are used, the source files of the libraries are also analyzed.

A number in ( ) following a function name or function block name indicates the number of inputs. However, EN inputs are not included in this number.

In case of a library, a function name is displayed as "library name.program name.function name" and a function block name is displayed as "library name.program name.function block name."

Note that the graphical view of the analysis results in the above figure is only available on the screen. The printout is text only.

If unrecognizable statements or scripts with incorrect syntax are found in ST, the following messages are displayed in the "Non-compliance" column.

Table C5.1.3-4 Non-compliance messages when error or warning occurs

Icon (color)	Message in Function(*1)	Message in Non-Compliance	Description
(red)	ST_FB.WHILE	Prohibited (line xx) (*2)	WHILE must not be used.
(red)	ST_FB.REPEAT	Prohibited (line xx) (*2)	REPEAT must not be used.
(red)	ST_FB.FOR	Loop nesting (line xx) (*2)	Nested loop in FOR loop must not be used.
(red)	ST_FB.FOR	Variable iteration count (line xx) (*2)	Initial value, end condition or step number in FOR loop must use a constant.
(red)	ST_FB.FOR	Iteration counter overflow (line xx) (*2)	FOR loop index counter range overflow.
(red)	ST_FB.EXIT	Outside loop (line xx) (*2)	EXIT must not be used outside FOR loop.

Continues on the next page

Table C5.1.3-4 Non-compliance messages when error or warning occurs (Table continued)

Icon (color)	Message in Function(*1)	Message in Non-Compliance	Description
(yellow)	ST_FB.RET	Interference Free (line xx) (*2)	Interference-free. Due to RETURN being used.
(yellow)	ST_FB.FOR	Excessive iterations (line xx) (*2)	Due to the number of iterations in FOR loop exceeding 500.
(yellow)	ST_FB.FBD_FB	Function Block Call (*3)	Due to ST calling FB.
(yellow)	ST_FB.FBD_FB	FB Parameter Access (*4)	Due to ST accessing FB parameter.
(yellow)	ST_FB.= FBD_FB.<>	Exact comparison (line xx) (*5)	Exact comparison should not be used to compare real numbers.

*1: The messages of ST_FB here are the examples of functions and function blocks. FBD_FB is a function block name example, not an instance name.
*2: xx in (line xx) will be replaced by the line number that are applicable to the message.
*3: The message will be displayed once even though the same FB is called many times by ST.
*4: The message will be displayed once even though same parameters in the same FB or different parameters in the same FB are accessed many times by ST.
*5: xx in (line xx) will be replaced by all the line numbers that are related to the ST message.

Even comparing the two real numbers using an equal operator or not equal operator in FBD or LD is classified as interference-free, and the message "Exact Comparison" will be displayed once per POU in the "Non-compliance" column.

SEE ALSO For more information about precautions on the structure when describing FU and FB with the ST language, refer to:

2., “Structured text” in POU Reference Manual (IM 32P03B20-01EN)

Checking analysis results of variables in programs

If you select [Variables] in the project tree, variables that do not satisfy the requirements of the program, such as naming rules and data type, are displayed in the right pane of the window.

The right pane displays names of variables that may cause errors or warnings and the programs, FUs or FBs to which those variables belong. Moreover, detailed information about errors and warnings is also displayed.

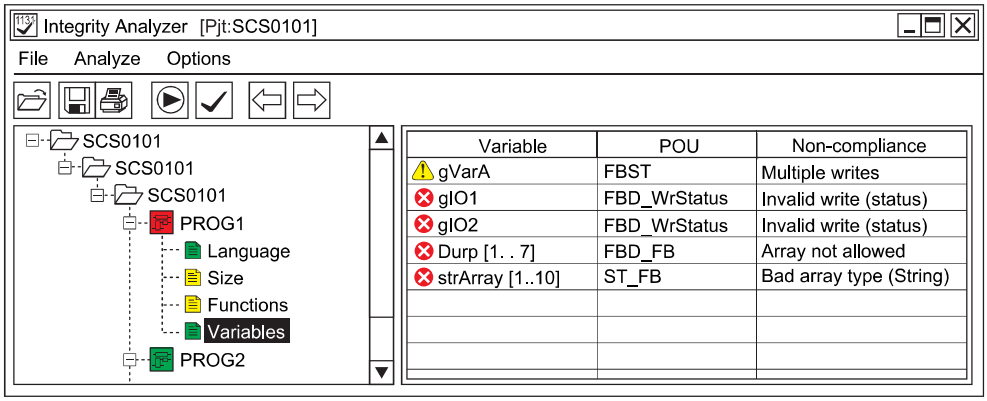

Figure C5.1.3-6 Example of variable analysis results

The Integrity Analyzer checks POUs to detect illegal writings: multiple writing to a variable, within a POU or by different POUs, and writing to output variable statuses. The preceding figure illustrates the result of the analysis. In the [POU] column, names of the POUs performing the illegal writing are displayed. If a POU contains multiple writing to the same variable, a warning message will be displayed for that POU. If multiple POUs are writing to the same variable, a warning message will be displayed for each of the POUs.

TIP

- Integrity Analyzer does not detect multiple writing to the same variable in ST objects. Such usage should be checked through a code review or unit test. However, multiple writing to the same variable by a certain ST object and other POU will be detected.
- Integrity Analyzer does not detect multiple writing to arrays or array elements.

Error messages will be displayed for the POUs that are writing to the status of output variables.

- Integrity Analyzer detects writing to the .status member of the IO_BOOL or IO_REAL variables having output attribute.

  For example, an error message is displayed in the following case: The value of internal variable bool1 (type BOOL) is written to the .status member of output variable DO010101 (type IO_BOOL).

Figure C5.1.3-7 Example where error message is displayed for POU (1)

- Integrity Analyzer detects writing to the entire IO_BOOL or IO_REAL variables having output attribute. Integrity Analyzer also detects the cases where the output (type IO_BOOL or IO_REAL) of an function block, such as B_TO_IB, is connected to an output variable.

  For example, an error message is displayed in the following cases:

  The value of internal variable IO_BOOL1 (type IO_BOOL) is written to the .status member of output variable DO010102 (type IO_BOOL).

Figure C5.1.3-8 Example where error message is displayed for POU (2)

The value of Q (type IO_BOOL), which is the output of function block B_TO_IB, is written to the .status member of output variable DO010103 (type IO_BOOL).

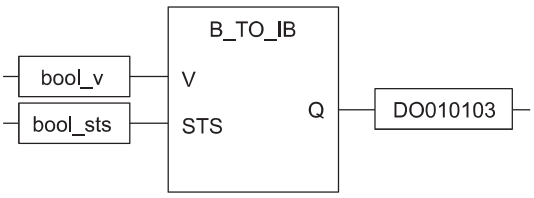

Figure C5.1.3-9 Example where error message is displayed for POU (3)

Table C5.1.3-5 Error messages displayed in Non-compliance column

Icon (color)	Indication in [Variable]	Message in Non-Compliance	Description
(yellow)	gVarA (*1)	Multiple writes	Multiple writing to this variable was detected.
(red)	gI01 (*2)	Invalid write(status) (*3)	Writing to the status of this output variable was detected.

*1: Variable name or FB instance name plus parameter name is displayed.
*2: Variable name is displayed.
*3: In parentheses ( ), the member name (i.e. status) or type name of the variable is displayed.

Note that the graphical view of the analysis results in the above figure is only available on the screen. The printout is text only.

If prohibited variables are used in ST, the following messages will be displayed as Non-Compliances.

Table C5.1.3-6 Error messages displayed in Non-compliance column

Icon (color)	Message in Variable	Message in Non-Compliance	Description
(red)	bArrayB[1..10000]	Array size	Number of array elements exceeds 500.
(red)	MultiArray[1..10][1..10]	Array dimensions	Multiple dimension arrays cannot be used.
(red)	bArrayC[10..20]	Array bounds	The array initial index must be 1.
(red)	strArray[1..10]	Bad array type({TYPE})	Array cannot contain prohibited data type (Detail is displayed in {TYPE}).
(red)	DO1	Bad type({TYPE})	Prohibited global variable cannot be used (Detail is displayed in {TYPE}).
(red)	COM_BOOL1	Bad local type({TYPE})	Prohibited local variable cannot be used (Detail is displayed in {TYPE}).
(red)	COM_BOOL2	Bad parameter type({TYPE})	Prohibited input/output parameter cannot be used (Detail is displayed in {TYPE}).
(red)	(*1)	Array check error	The analyzer detected a defect of a mechanism which checks the access outside the range of array.

*1: Message cannot be displayed.

If prohibited variables are used in FBD or LD, the following messages will be displayed as Non-Compliances.

Table C5.1.3-7 Error messages displayed in Non-compliance column

Icon (color)	Message in Variable	Message in Non-Compliance	Description
(red)	bArrayA[1..10]	Array not allowed	Array must not be used in FBD or LD.

These graphical analysis results can only be viewed in the window; it cannot be printed out.

C5.2 Cross Reference Analyzer

Cross Reference Analyzer displays the differences between the previously downloaded application (the application currently running in an SCS) and the application to be downloaded, and the extent to which the download will affect the operation in a window by highlighting them visually, in order to limit the range of retesting caused by changes in an application logic.

You can check programs that require retesting. You can also print the analysis results.

Cross Reference Analyzer detects programs that depend on the modified program. You should retest the detected programs. A list of programs requiring retesting is displayed; they can be acknowledged upon checking the analysis results of each program.

If unintended program changes and dependencies are detected, the application logic must be modified. Modify the application logic, perform a build operation and then analyze the application logic with Cross Reference Analyzer again.

If no program is found for retesting, retesting will not be performed. However, since the modifications on a certain items may not be discovered for retesting, these modified items need to be tested accordingly.

IMPORTANT

- Before downloading application logic to SCS, run Integrity Analyzer and Cross Reference Analyzer and acknowledge.
- Cross Reference Analyzer detects the differences between the application currently running in an SCS and the application to be downloaded.

  It does not detect differences with an application running in a virtual test.

  In a virtual test, it is possible to execute and test an application logic on a PC without having to perform analysis by both analyzers.

Cross Reference Analyzer also has the function to compare an SCS database with the master database of other SCS project with the same domain number and station number. Using this function, you can verify that a project created from an existing project is exactly the same in functionality as the original project. This eliminates the need to test all the POUs when you regenerate a project.

SEE ALSO For more information about the items that require retesting but not detected by Cross reference Analyzer, refer to:

C5.2.5, “Precautions on Cross Reference Analyzer” on page C5-46

C5.2.1 Methods for checking analysis results

This section explains how to check results of analysis by Cross Reference Analyzer.

Starting Cross Reference Analyzer

1. After a build operation, select [Engineering] from the [Tools] menu of SCS Manager.
   The Engineering launcher menu appears.
2. Select [Cross Reference Analyzer] from the Engineering launcher menu.
   Cross Reference Analyzer starts up, automatically analyzes the application logic in question and displays the analysis results.

TIP

Cross Reference Analyzer displays or prints the differences between the previously downloaded application logic and the application logic to be downloaded, and the extent of the differences. If an application logic has never been downloaded, there is no equivalent to a previously downloaded application logic. In this case, Cross Reference Analyzer displays all programs as new.

IMPORTANT

If Cross Reference Analyzer has already started when you attempted to perform a build or download operation, a dialog box prompting to close Cross Reference Analyzer appears. In this case, neither the build nor the download operation is performed.

Procedure for using Cross Reference Analyzer

The procedure for using Cross Reference Analyzer is explained below.

1. Checking programs in Dependency Tree
   Check the results of analysis by Cross Reference Analyzer in Dependency Tree to identify the programs requiring retesting. The programs requiring retesting are those with changes and those that depend on the changed programs.
2. Checking with analysis result report
   Check the Cross Reference Analysis Report showing the analysis results, either directly in a window or by printing it out.
3. Acknowledgement of differences between application logics and extent of influence
   A list of programs requiring retesting is displayed in the Acknowledge Dependencies dialog box; acknowledge them upon checking the analysis results of each program.

   If unintended changes and independencies are detected or the application requires modification, close Cross Reference Analyzer without approving the programs. Modify the application logic, perform a build operation and then analyze the application logic by Cross Reference Analyzer again.
4. Saving and printing analysis results
   Save the analysis results and print them if necessary.

Checking programs in Dependency tree

Dependency Tree allows checking the results of comparing the application logic running on an SCS and the application logic to be downloaded, as well as programs that depend on the changes. These programs are the ones that require retesting and review.

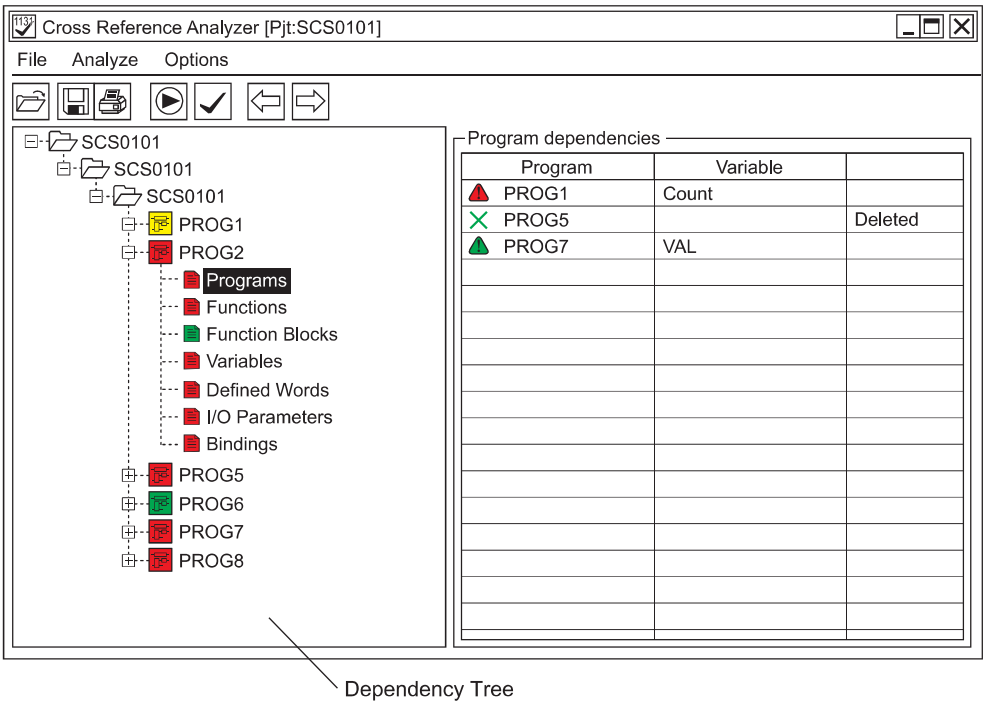

Figure C5.2.1-1 Example of program analysis result by Cross Reference Analyzer

These graphical analysis results can only be viewed in the window; they cannot be printed out.

How to understand icon colors

Dependency Tree displays SCS projects, configurations, resource and programs in a tree structure. Double-click a program icon to display icons for [Programs], [Functions], [Function Blocks], [Variables], [Defined Words], [I/O Parameters] and [Bindings]. Analysis results are shown using colored icons placed to the left of the labels in the tree.

Table C5.2.1-1 Meaning of colors of icons on the left side of Dependency tree

Icon color	Description
Red	Red icons indicate that programs or function blocks and functions used in the program have been changed.
Yellow	Yellow icons indicate dependencies on changed programs. Although the programs themselves have not been changed, it is necessary to retest or examine the code in order to check that it is not affected by changes made to the dependent programs. A yellow icon may also indicate that the program name was changed. Retesting is not required in this case.
Green	Green icons indicate that the changes do not affect other programs. Neither retesting nor review is required.

If you select an individual icon in Dependency Tree, detailed analysis information of the item to be checked is displayed on the right pane of the window. The right pane shows the status of changes of the item selected in Dependency Tree and the extent of influence of the changes.

If you select an individual icon below the program layer, the following colored icons are displayed next to the corresponding program components in the right pane of the window.

Table C5.2.1-2 Meaning of icons in the right pane of the window when an icon below the program icon is selected

Icon (color)	Meaning
 (green)	An item in the right pane is dependent on the program selected in Dependency Tree but not affected directly by the changes.
 (red)	An item in the right pane is dependent on the program selected in Dependency Tree and affected by the changes. In other words, the item was directly changed or newly created, or is dependent on the changed areas.
 (green)	An item in the right pane used to depend on the program selected in Dependency Tree but the dependency was eliminated by the change.

SEE ALSO For more information about details on how to read the analysis results of the program in Dependency Tree, refer to:

C5.2.3, “Confirmation of analysis results by Dependency tree” on page C5-30

Checking with Analysis report

The Cross Reference Analysis Report organizes and summarizes all the information in analysis results. It can be displayed in a window, printed or saved in a file (RTF or TEXT format) as a report.

The Cross Reference Analysis Report is used mainly for the following two applications.

- It provides more detailed information than the information obtained by expanding Dependency Tree.
- The Cross Reference Analysis Report can be used as a part of operation records or application construction documentation, by printing it out or saving it to a file. The Cross Reference Analysis Report also includes information about whether or not acknowledgement is made in the Acknowledge Dependencies dialog box, along with comments. In order to record acknowledged items, print or save the report in a file after acknowledgement.

Application Logic Cross Reference Analysis Report

Project : SCS0101
Configuration : SCS0101

PROG8	Function block modified, Variable changed, Defined Word changed	

Not acknowledged

Number of programs requiring acknowledgement : 4

Figure C5.2.1-2 Example of Cross Reference report (RTF format file)

Displaying Analysis report

1. Select a resource in Dependency Tree and select [Save Analysis] in the [File] menu. Alternatively, click [Save current analysis history] button in the toolbar;
   the analysis results are saved.
2. Select [Report] from the [Analyze] menu.
   The saved analysis results are displayed as an analysis report.

IMPORTANT

Make sure to save the analysis results before creating an analysis report.

If the current analysis results and acknowledgement history are not saved before creating an analysis report, a message prompting you to save the history is notified. If you click [Yes] button in the message box, the current analysis results and acknowledgement history are saved, overwriting the history saved before in the process, and an analysis report is created. An analysis report is not created if you click [No] button.

Displaying previous Analysis report

By running [Previous Report] in the [Analyze] menu, you can display the report of the analysis result for the previously downloaded application. The report file is saved in .rtf format. The report date of the previous analysis report is the date that the analysis report was last saved before downloading.

Acknowledgement of program dependencies

If the analyzed application logic contains programs requiring retesting because they were changed or depend on the changed programs, it is necessary to acknowledge these programs one by one in the Acknowledge Dependencies dialog box.

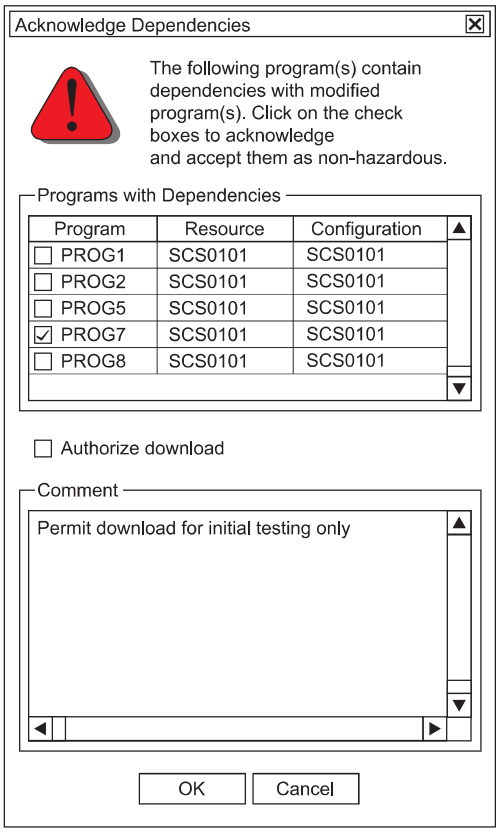

Figure C5.2.1-3 Acknowledge Dependencies dialog box

Displaying the Acknowledge Dependencies dialog box

Select [Authorize] in the [Analyze] menu. Alternatively, click "Display program dependency acknowledge dialog" button in the toolbar. The Acknowledge Dependencies dialog box appears.

Acknowledgement of programs with changes and dependencies

The Acknowledge Dependencies dialog box displays programs indicated with red or yellow icons in Dependency Tree. In order to download the application logic to an SCS, it is necessary to acknowledge all the programs displayed in the dialog box.

The user must confirm the following items and then check the check box for each program.

- Retesting and review must be planned and executed for programs indicated by red and yellow icons.
- No unintended modifications are included.
- No unintended dependencies (e.g., unintended sharing of global variables) are included.

Authorize download check box

Selecting this check box allows downloading the application logic to an SCS without acknowledging individual program dependencies.

IMPORTANT

- Use this check box only at the beginning of application development such as during debugging an application logic.
- While the SCS is in use for actual plant, acknowledge the dependencies of individual programs without selecting this check box.
- It is recommended to enter the reasons in the comment field when the Authorize Download check box is selected.

Comment

Memos related to changed areas, results of analysis for the purpose of acknowledgement, etc. can be entered as comments. The Cross Reference Analysis Report includes information about whether or not programs are acknowledged, along with comments.

C5.2.2 Cross Reference Analyzer window structure

This section explains the window structure of Cross Reference Analyzer.

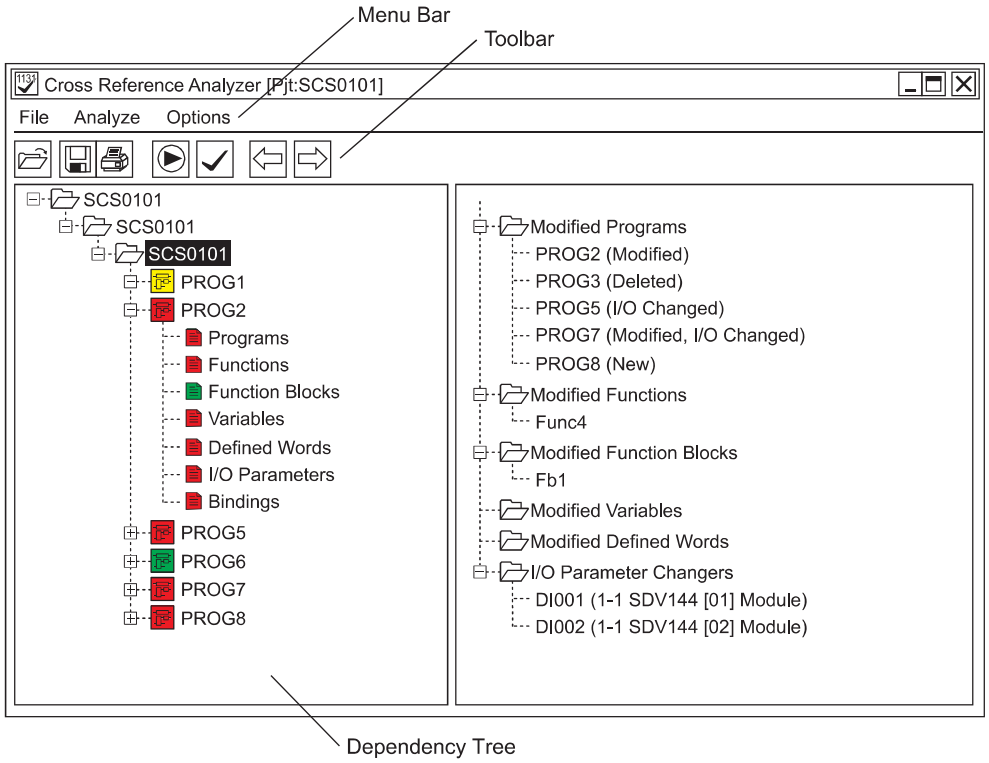

Figure C5.2.2-1 Cross Reference Analyzer window structure

Menu bar

The menu bar provides the following menus.

- [File] menu
- [Analyze] menu
- [Options] menu

The menu items of each menu are explained below.

Table C5.2.2-1 File menu

Menu item	Description
Print Report	Prints an analysis report saved by [Save Analysis]
Save Report	Creates an analysis report and saves it in a file (RTF or TEXT format)
Save Analysis	Saves analysis results and acknowledgement status.
Exit	Closes Cross Reference Analyzer

Table C5.2.2-2 Analyze menu

Menu item		Description
Start	With History	Performs analysis and compares it with the results of previous acknowledgement and analysis. If the areas acknowledged in the previous analysis are not modified this time, it is regarded as if they have already been acknowledged.
	Without History	Performs analysis without comparing it with results of previous acknowledgement and analysis
Report		Creates and displays the analysis report in the Cross Reference Analysis Report window
Previous Report		Displays previous analysis report.
Authorize		Displays the Acknowledge Dependencies dialog box.
Compare with Original Project		Compares a work database with the master database of another project

Table C5.2.2-3 Options menu

Menu item	Description
Settings	Displays the Settings dialog box

IMPORTANT

Make sure to save the analysis results before creating an analysis report.

If the current analysis results and acknowledgement history are not saved before creating an analysis report, a message prompting you to save the history is notified. If you click [Yes] button in the message box, the current analysis results and acknowledgement history are saved, overwriting the history saved before in the process, and an analysis report is created. An analysis report is not created if you click [No] button.

Toolbar

The toolbar provides the following buttons.

Table C5.2.2-4 Toolbar buttons

Button	Name	Description
	Save current analysis history	Saves analysis results and acknowledgement status.
	Print report for a selected resource	Prints analysis reports.
	Display program dependency acknowledgement dialog	Displays the Acknowledge Dependencies dialog box
	Previous dependency change	Selects the icon of the previous element that was changed or affected relative to the currently selected icon in Dependency Tree (the upward direction in the tree).
	Next dependency change	Selects the icon of the next element that was changed or affected relative to the currently selected icon in Dependency Tree (the downward direction in the tree).

Dependency tree

Dependency Tree is displayed on the left pane of the Cross Reference Analyzer window.

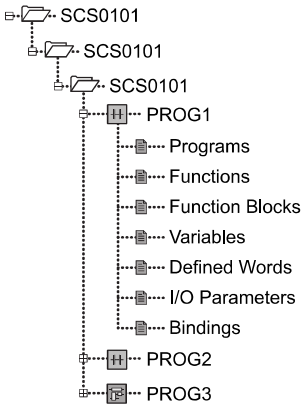

Figure C5.2.2-2 Displaying Dependency tree

Each level of Dependency Tree can be expanded or collapsed by double-clicking an icon, or text label, or clicking the +/- button on the left edge.

Analysis results of an item selected in Dependency Tree is displayed in the right pane.

The display arrangement of Dependency Tree can be defined in Settings dialog box.

Displaying the Settings dialog box

On the [Options] menu, click [Settings]. The Settings dialog box appears.

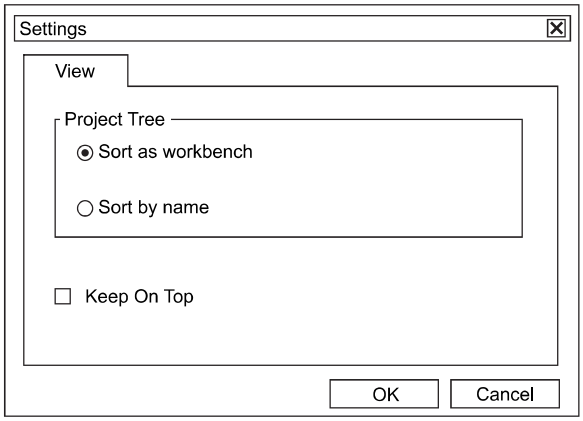

Figure C5.2.2-3 Settings dialog box

- Project Tree
  Sort as workbench: the Dependency Tree is displayed in the same order as the display with Workbench.

  Sort by name: Contents displayed on Dependency Tree are sorted by names alphabetically.
- Keep On Top
  Cross Reference Analyzer window is kept always on top.

C5.2.3 Confirmation of analysis results by Dependency tree

This section explains how to understand the detailed information displayed when layers below resources (SCS projects) are selected in Dependency Tree.

Checking resources

If you select a resource (SCS projects) in Dependency Tree, a list of analysis results of the resource is displayed in the right pane of the window. The list displays changes related to the selected SCS project.

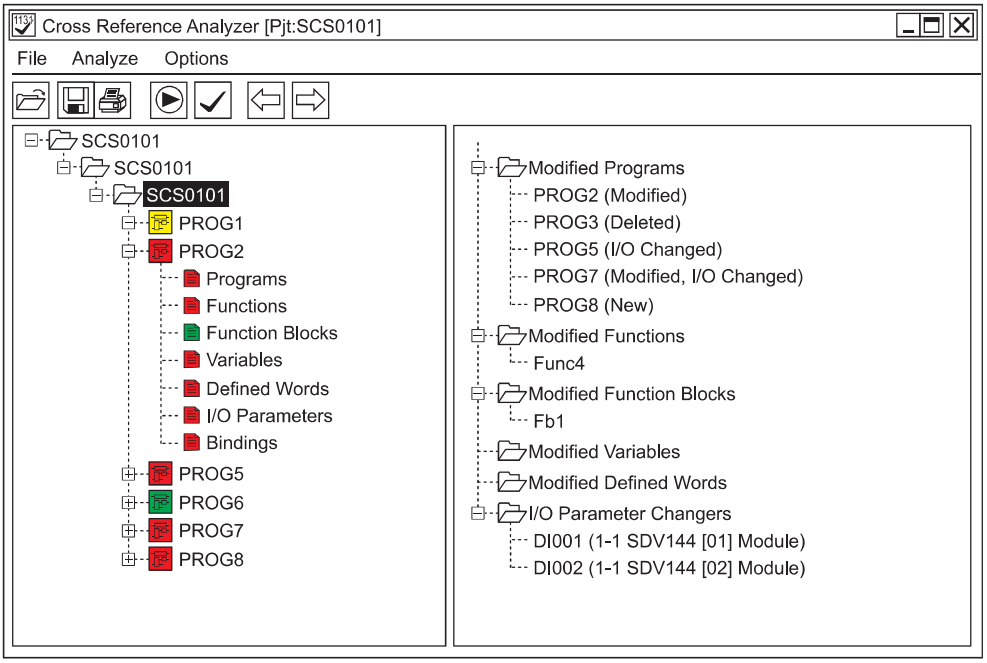

Figure C5.2.3-1 Dependency tree of Cross Reference Analyzer

The analysis results of the selected SCS project are displayed in a tree structure in the right pane. The modifications are displayed as classified groups of modified programs, modified functions, modified function blocks and input/output parameter changes.

Each category can be expanded and collapsed by clicking the +/- button to the left of the category.

Icon colors and classifications of program names

The following table explains icon colors of program names in Dependency Tree and classifications displayed to the right of program names in the "Modified Programs" tree.

Table C5.2.3-1 Icon colors and classifications of program names

Icon color of program name in Dependency Tree	Classification	Description	Display in the right pane (*1)
Red	Modified	The program itself has been changed.	Yes
	Instruction modified (*2)	The program itself has not been changed, but the database downloaded to SCS has been changed.	Yes
	Function modified	The program itself has not been changed, but dependent FUs have been changed. Or user-defined FB is changed to user-defined FU.	Yes
	Function block modified	The program itself has not been changed, but dependent FBs have been changed. Or user-defined FU is changed to user-defined FB.	Yes
	Variable changed	The settings of variable or function block instance used in the POU is changed.	Yes
	Defined Word changed	The value of Defined word used in the POU is changed.	Yes
	I/O changed	The program itself has not been changed, but a dependent input/output has been changed. Otherwise, information regarding a dependent subsystem communication I/O FB, information regarding a PROFINET communication input FB, information regarding a fire and gas communication input FB, or SCS link transmission I/O FB has been changed.	Yes
	New	The program itself has been newly added. Programs added by importing are also regarded as being newly added.	Yes
Yellow	Not modified	The program became dependent as it shares variables with a program requiring code review. The program itself, dependent functions, function blocks and inputs/outputs have not been changed.	No
	Renamed	The program name has been changed. No influence other than the name change. Program name change does not require acknowledgement on the Acknowledge Dialog box.	Yes
Green	(none)	The program is not affected by changes.	No
None (*3)	Deleted	The program has been deleted.	Yes

*1: Yes: Displayed in the right pane.
No: Not displayed in the right pane.
*2: When "Instruction modified" is displayed, please contact Yokogawa's service department.
*3: The program has been deleted and the program name is not displayed in Dependency Tree.

TIP

If the execution order of programs is changed, or a program is inserted or deleted, all the subsequent programs are regarded as being changed. Their icons therefore become red, and retesting of the programs is required.

Displaying analysis results of Functions and Function Blocks

Dependency Tree displays results of analyzing FUs and FBs as part of the summary for the program that calls the FUs and FBs.

- Dependency Tree displays only icons for program names. Icons for FUs and FBs are not displayed.
- If you expand an icon of a program name, the analysis results for the FUs and FBs called by the program are displayed, in addition to the analysis results of the program itself.
- If FUs and FBs have been changed, the icon of the program name that calls these FUs and FBs becomes red.

- If a program on which FUs and/or FBs are dependent has been changed, the icon of the program that calls the FUs and FBs becomes yellow even if no change has been made to the FUs and FBs themselves.
- If you select a resource (SCS project) in Dependency Tree, "Modified Functions" and "Modified Function Blocks" in the right pane display changed FUs and FBs, respectively.

Judging dependencies between POUs

Cross Reference Analyzer judges that there are dependencies between POUs in the following cases. If dependent POUs have been changed, retesting or review is required even if the program itself has not been changed.

Shared global variables

POUs that share global variables are dependent on each other. POUs are considered to be sharing global variables in the following cases.

- POUs are reading and writing directly to/from global variables.
- POUs are reading and writing to/from global variables within called FBs.

If multiple POUs satisfy one of the two conditions above for the same global variable, the POUs are dependent on each other.

The relationship between the global variables and program is displayed in the Current Version Shared Variable Changes Cross Reference item of the Cross Reference Analysis Report. If FBs read and write to/from the same global variables, only the name of the program that uses those FBs is displayed; the names of the FBs are not displayed.

Use of functions or Function Blocks

If a program calls FUs or FBs, there is a dependency between the calling side and the called side. For example, if A calls B and B calls C, not only A and B, and B and C that have direct calling relations, but also A and C, which only have an indirect calling relation, are considered to be dependent on each other.

Checking programs (POU)

When you select a program name in Dependency Tree, a list of program statuses is displayed in the right pane of the window. The list displays the cross reference status (e.g. New, Modified, Binding Error, Function modified, Function block modified) and acknowledgement status of the program.

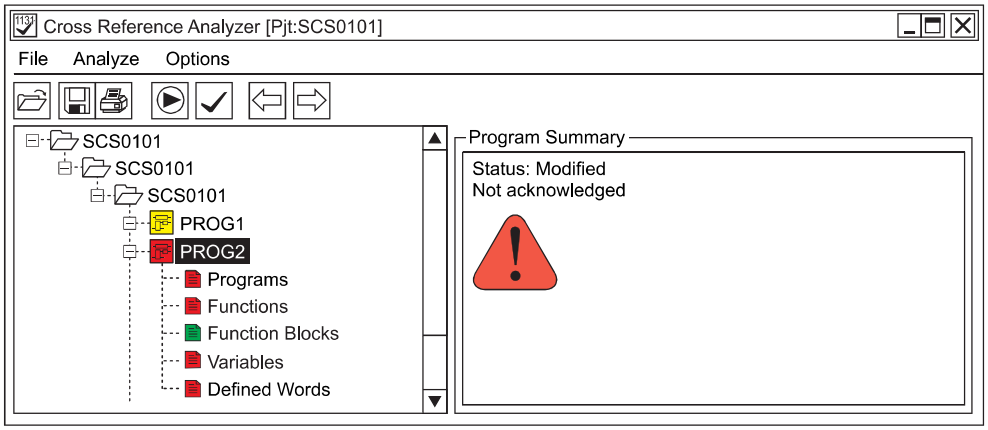

Figure C5.2.3-2 Analysis results of a programs (POU)

Table C5.2.3-2 Meaning of icons displayed on the left side of program names

Icon color	Meaning
Red	The program itself or items that are directly depending on it (FU, FB, input/output) have been changed.
Yellow	Dependencies requiring review are present in the program (the program has not been changed).
Green	The program has not been affected by changes.

Checking programs

If you select [Programs] in the Dependency Tree, programs dependent on the selected program are displayed in a column in the right pane of the window. If multiple variables are shared among programs, all the variables shared in the programs are displayed in the "Variable" column.

Check to see if there is any unintended dependencies. For example, if global variables are shared unintentionally, modify the program to eliminate the dependencies. The programs that have dependencies but not have been changed are displayed with green icons. It is necessary to check programs displayed with green icons as well.

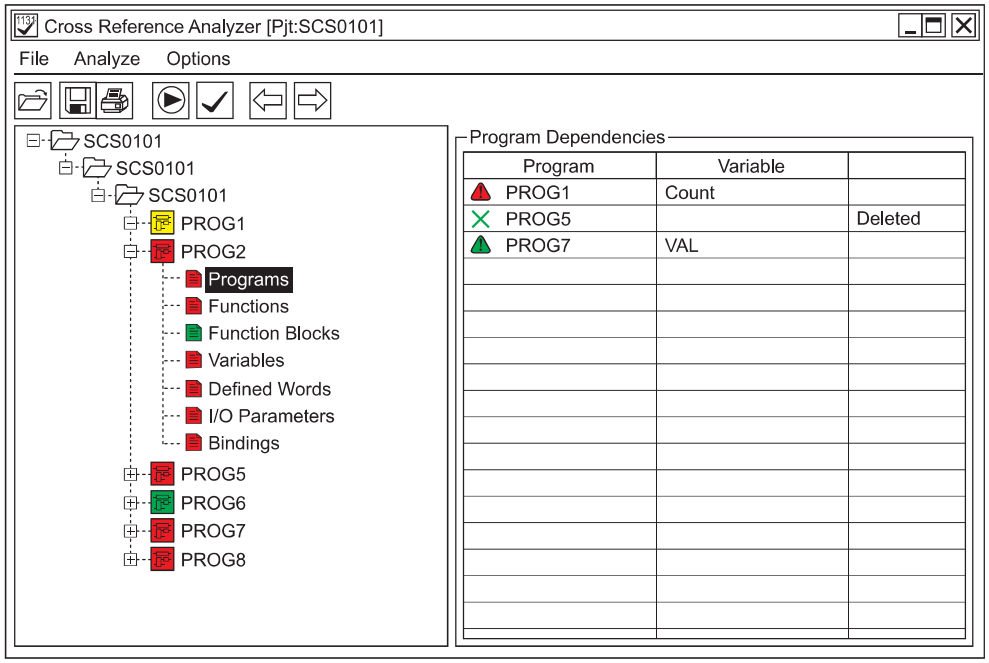

Figure C5.2.3-3 Analysis results of programs

In the preceding figure, PROG2 is selected in the Dependency Tree, and dependencies and changes related to PROG2 are displayed in the right pane of the window.

PROG2 has dependencies on PROG1 and PROG 7. PROG1 has been changed, while PROG7 has not been changed. Although PROG2 had a dependency on PROG5, the dependency on PROG5 is eliminated in the application to be downloaded.

Checking functions

If you select [Functions] in the Dependency Tree, FUs and library FUs directly changed or indirectly affected by changes are displayed in the right pane of the window.

Note that simply changing the order of FUs is irrelevant for the analysis.

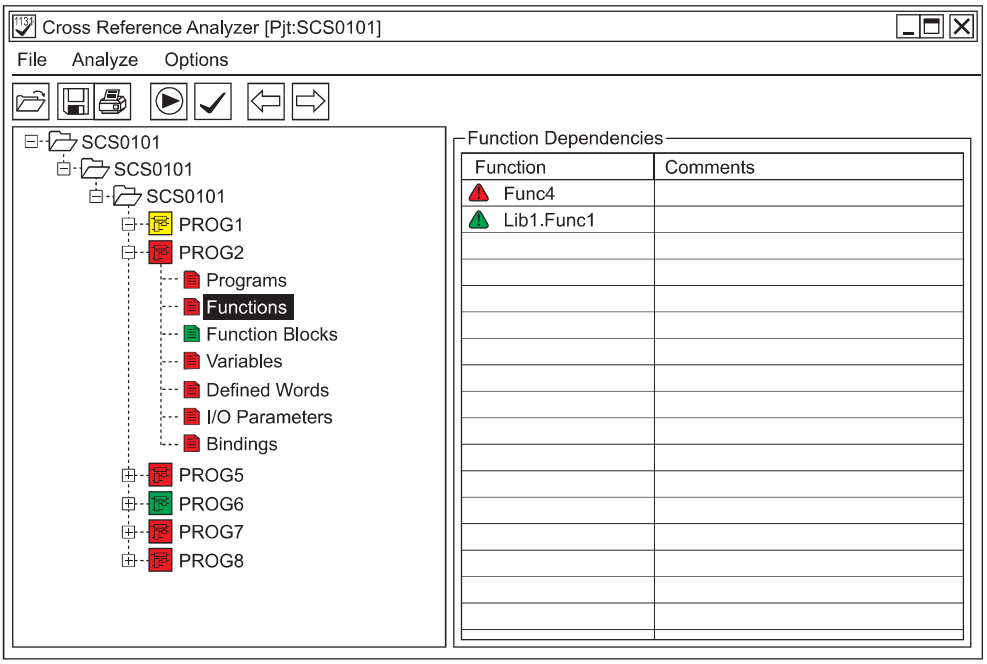

Figure C5.2.3-4 Results of analyzing functions

The preceding figure indicates that PROG2 uses Func4 and Func1 defined in library Lib1. Func4 has been changed, while Lib1.Func1 has not been changed.

TIP

FUs of libraries are displayed using the format "library name.function name."

Checking Function Blocks

If you select [Function Blocks] in the Dependency Tree, FBs and library FBs directly changed or indirectly affected by changes are displayed in the right pane of the window.

Note that simply changing the order of FBs is irrelevant for the analysis.

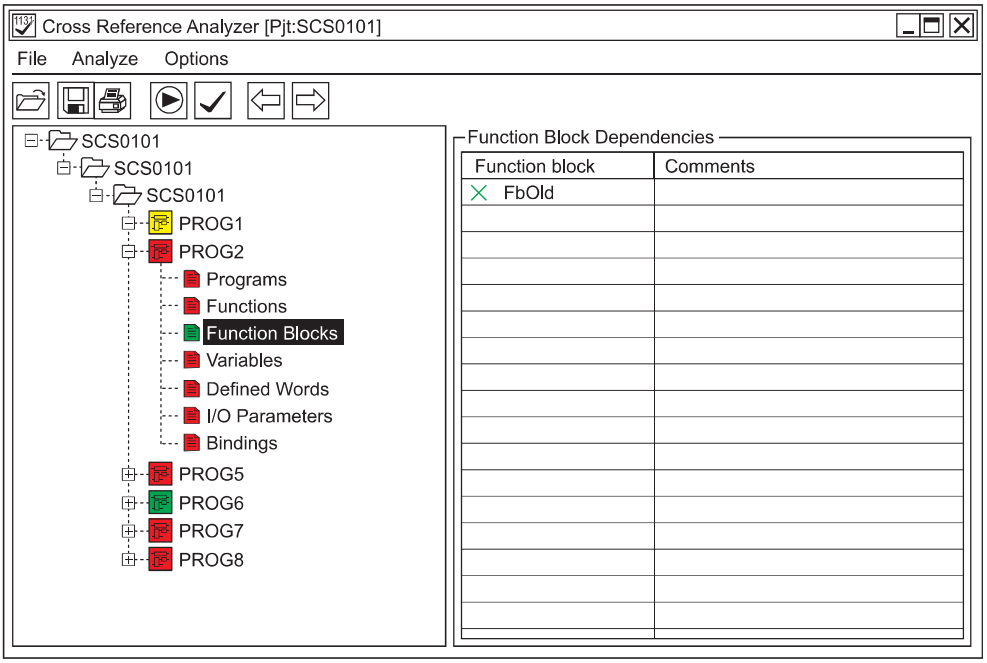

Figure C5.2.3-5 Results of analyzing Function Blocks

The preceding figure indicates that PROG2 used the FbOld function block before, but does not use it any longer.

TIP FBs of libraries are displayed using the format "library name.function block name."

Checking variables

When [Variables] is selected in the Dependency Tree, variables and FB instances whose settings have changed are displayed in the right pane of the window.

These variables and FB instances are used in the selected program (PROG2 in the following figure), or in FU or FB called by the program.

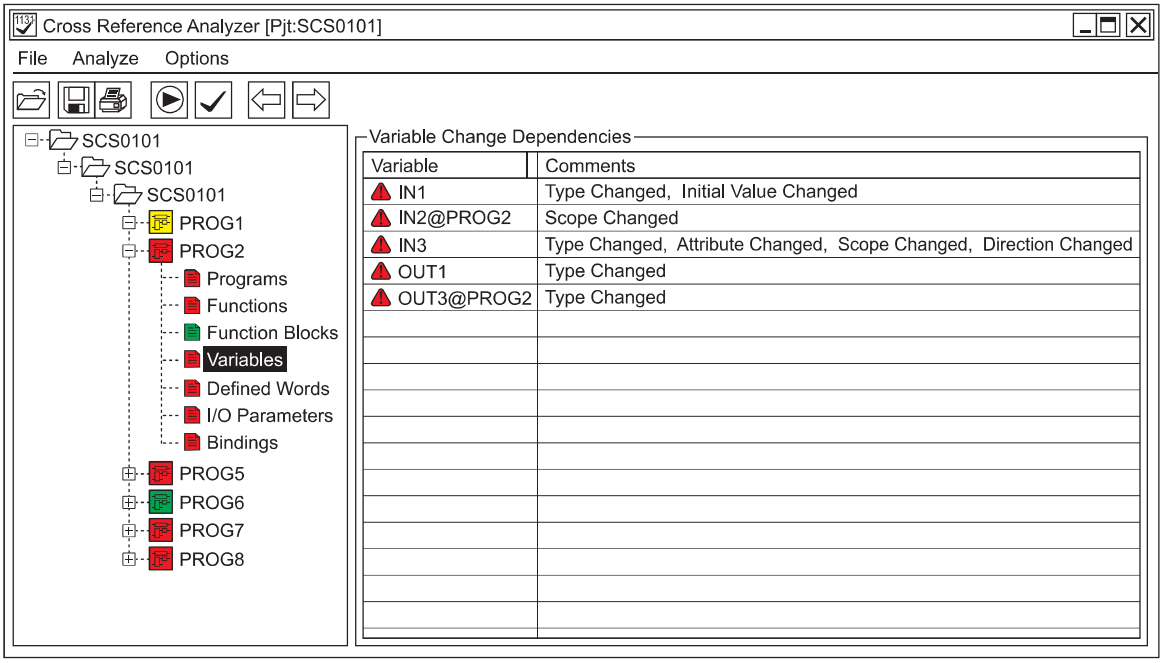

Figure C5.2.3-6 Result of analyzing variables

In the previous figure, IN1 indicates that Type and Initial value were changed.

The following table shows whether a change to the variable or FB instance is detected or not.

Table C5.2.3-3 Changes to variables or FB instances and detection

Item	Detected(*1)	Remarks
Name	No	Changed names are regarded as added variables.
Alias	No	-
Type	Yes	Changes to Type of FB instances included.
() [Specify the number of characters in a STRING variable]	Yes	STRING variables are not allowed to use.
Init. value	Yes	-
Dimension [The extent of index of array]	Yes	Arrays should not be used in FBD and LD.
Group	No	-
Attribute [Read/Write/Free]	Yes	-
Scope	Yes	-
Direction [Input/Output/Internal]	Yes	-

Continues on the next page

Table C5.2.3-3 Changes to variables or FB instances and detection (Table continued)

Item	Detected(*1)	Remarks
Retain [Yes/No]	No	-
Wiring	No	Changed wiring is categorized as "I/O changed."
Address	No	-
Comment	No	-

*1: Yes: Detected as change
No: Not detected as change

Checking defined word

If you select [Defined Words] in the Dependency Tree, the changed defined words are displayed in the right pane of the window.

These defined words are used in the selected program (PROG2 in the following figure), or in FUs or FBs called by the program.

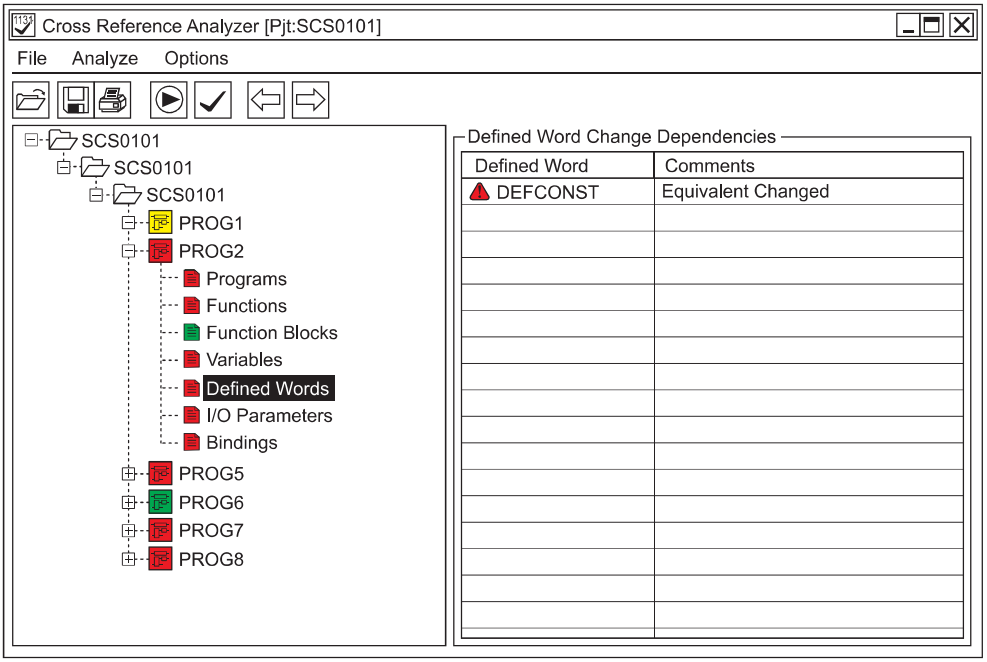

Figure C5.2.3-7 Result of analyzing defined words

The preceding figure shows that the value of DEFCONST was changed.

The following table shows whether a change to the Defined word is detected or not.

Table C5.2.3-4 Changes to defined word and detection

Item	Detected (*1)	Remarks
Word	No	Changed names are regarded as added Word.
Equivalent	Yes	-
Comment	No	-

*1: Yes: Detected as change
No: Not detected as change

Checking input/output parameters

If you select [I/O Parameters] in the Dependency Tree, a list of input/output variables with changed input/output module or input/output channel parameters is displayed in the right pane of the window.

These input/output variables are used in the selected program (PROG2 in the figure below) or FUs and FBs called by the program.

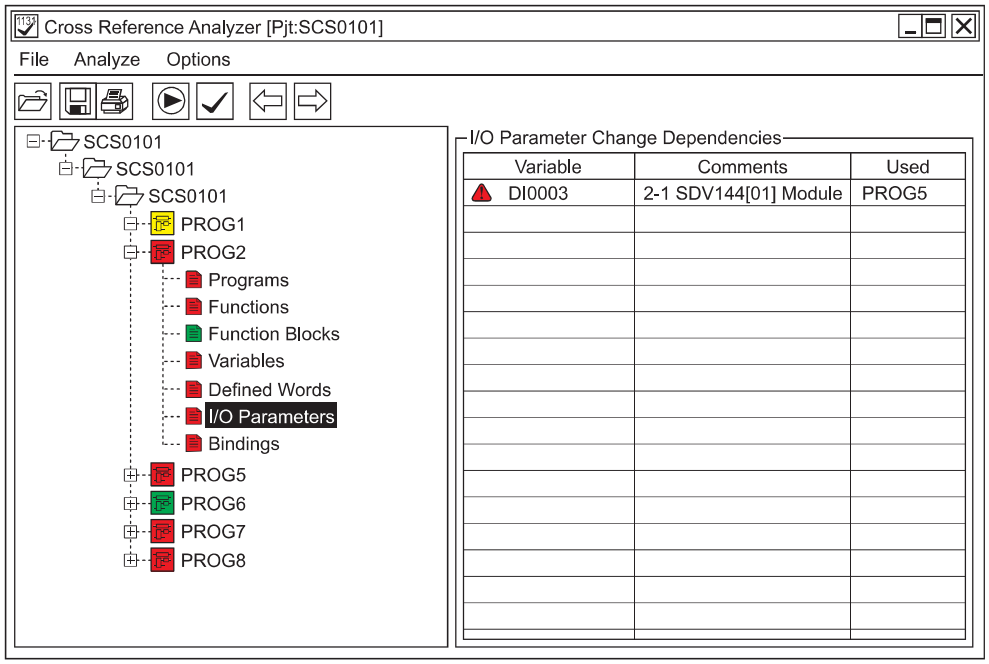

Figure C5.2.3-8 Results of analyzing input/output parameters

The preceding figure shows the following.

- PROG2 uses the variable DI0003.
- The input/output parameters related to DI0003 have been changed.

SEE ALSO For more information about details on how to check the input/output parameters, refer to:

"■ Checking when input/output parameters have been changed" on page C5-40

Explanation of entries in the Comments column

The format of the entries in the Comments column is explained below.

- For FIO
  <Node number>-<slot number><module model>[<channel number>]<wiring information><parameter information>
- For N-IO
  <Node number>-<unit number><slot number><module model>[<channel number>]<wiring information><parameter information>

Wiring information (omitted if there are no changes)

- New addition: Wiring-Added
- Change: Wiring-Changed

Parameter information (omitted if there are no changes)

- Parameters common to modules have been changed: Module
- Channel parameters have been changed: Channel
- Both are changed: Module Channel

Extent of influence of input/output parameter changes

The table below shows the influence that changes made to input/output parameters have on an application logic.

Table C5.2.3-5 Influence of I/O parameters

Classification	Example	Influence on application logic
Changes affecting data	Specification of Input Processing at Fault	Member v of the IO_BOOL and IO_REAL structure of input/output variables is influenced.
Changes affecting data status	Specification of disconnection detection specification of short-circuit detection	Member status of the IO_BOOL and IO_REAL structure of input/output variables, or the system FB notifying the status of an inputs and outputs is influenced.
Changes not affecting application logic	Comment	No influence on an application logic

SEE ALSO For more information about influence on system FBs notifying the status of inputs and outputs, refer to:

"■ Influence of input/output changes" on page C5-46

Changing Scan period

If you change the scan period of an application logic, the system automatically changes all internal parameters of the N-IO module common area of an SCS. As a result, the analysis results of Cross Reference Analyzer become as follows.

- The analysis results of all programs accessing the I/O variables that are wired to an N-IO module become "I/O Changed" and the color of the corresponding program icons becomes red.
- "I/O Parameter changes" in the right pane of the window and the "Current Version I/O Parameter Changes Cross Reference" item of the Cross Reference Analysis Report display "Module" indicating changes (I/O module common area) for all I/O variables that are wired to an N-IO module.

Checking binding variables

If you select [Bindings] in the Dependency Tree, binding variables depending on the selected program (PROG2 in the following figure) are displayed in the right pane of the window.

These binding variables are used by the program or FBs called by the program.

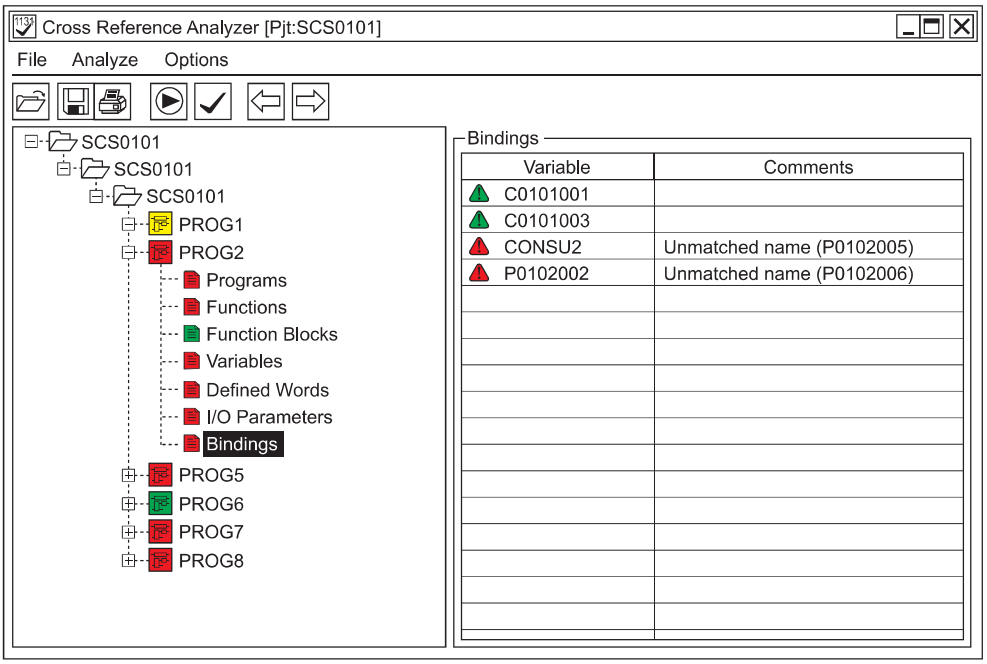

Figure C5.2.3-9 Results of analyzing bindings

The preceding figure shows the following.

- Four variables are used in PROG2 for inter-SCS safety communication.
- Binding is set properly for C0101001 and C0101003.
- For CONSU2 and P0102002, binding is set with variables that do not match the specified names.

C5.2.4 Checking with Analysis report

An analysis report displays analysis results in the same order as in Dependency Tree. It also displays the acknowledgement status set in the Acknowledge Dependencies dialog box. An analysis report can also be printed.

This section describes how to check dependencies for the following cases:

- When I/O parameters have been changed
- When information related to a subsystem communication I/O FB has been changed
- When information related to a PROFINET communication input FB or fire and gas communication input FB has been changed
- When settings of SCS link transmission have been changed
- When inter-SCS safety communication is used

Checking when input/output parameters have been changed

The results of analysis when input/output parameters have been changed are displayed in the "Current Version I/O Parameter Changes Cross Reference" item of the Cross Reference Analysis Report as a dependency between the input/output variables whose parameters were changed and programs.

An example of a case where input/output parameters have been changed is shown below.

Example:

DO modules (SDV531) are mounted on slots 3 and 5 of node 2 of an SCS

(1) Parameters in the module common area of slot 3 are changed

(2) Channel parameters of channel 5 of slot 3 and channel 7 of slot 3 are changed

(3) Wiring is added for channel 2 of slot 3 and channel 1 of slot 5

(4) Wiring is changed for channel 3 of slot 3 and channel 2 of slot 5

Assuming the changes outlined in (1) to (4) are made, the Cross Reference Analysis Report displays as follows:

Current Version I/O Parameter Changes Cross Reference

Variable	Comments	Used
V020301	2-3 SDV531 [01] Module	PROG5 .....(1)
V020302	2-3 SDV531 [02] Wiring-Added Module	PROG5 .....(3)+(1)
V020303	2-3 SDV531 [03] Wiring-Changed Module	PROG5 .....(4)+(1)
V020304	2-3 SDV531 [04] Module	PROG5 PROG6 .....(1)
V020305	2-3 SDV531 [05] Module Channel	PROG6 .....(2)+(1)
V020306	2-3 SDV531 [06] Module	PROG6 .....(1)
V020307	2-3 SDV531 [07] Module	PROG6 .....(1)
V020308	2-3 SDV531 [08] Module	PROG5 PROG6.....(1)
V020501	2-5 SDV531 [01] Wiring-Added	PROG7 .....(3)
V020502	2-5 SDV531 [02] Wiring-Changed	PROG7 .....(4)
V020507	2-5 SDV531 [07] Channel	PROG7 .....(2)

- Variable column

  Names of input/output variables.

- Comments column

The comments are displayed in the following formats:

- For FIO
  <Node number>-<slot number><module model>[<channel number>]<wiring information><parameter information>
- For N-IO
  <Node number>-<unit number><slot number><module model>[<channel number>]<wiring information><parameter information>

Wiring information (omitted if there are no changes)

- New addition: Wiring-Added
- Change: Wiring-Changed

Parameter information (omitted if there are no changes)

- Parameters common to modules have been changed: Module
- Channel parameters have been changed: Channel
- Both have been changed: Module Channel

- Used column

  Displays names of programs accessing relevant input/output variables. If FBs are reading or writing to/from the input/output variables, only the names of programs using the FBs are displayed and the names of the FBs are not displayed.

Checking when information related to a subsystem communication I/O FB, PROFINET communication input FB, or fire and gas communication input FB has been changed

After analyzing the changed settings which are relevant to a subsystem communication I/O FB, PROFINET communication input FB, or fire and gas communication input FB, the changed settings and their crossed references with programs will be displayed in the section for "Current Version I/O Parameter Changes Cross Reference" in the Cross Reference Analysis Report.

Example:

A communication module (ALR111M) is located at SCS Node 1, Slot 3 and the following variable names are defined:

- Definition 1: SCI_B01 - SCI_B04
- Definition 2: SCO_B01 - SCO_B03
- Definition 3: SCO_I01 - SCO_I04

In this case, implement the following changes.

(1) Parameters for definition 1 are changed (Node1-Slot3).

(2) A wiring for SCO_B04 is added to definition 2 (Node1-Slot3).

(3) A wiring for SCO_I01 of definition 3 is changed (Node1-Slot3).

(4) A new communication module (ALR111M) is added to Node2-Slot4 with a new definition and wiring SCO_R01 added.

After (1) to (4) are implemented, the Cross Reference Analysis Report display will be as follows.

Current Version I/O Parameter Changes Cross Reference

Variable	Comments	Used
SCI_B01	1-3 ALR111M Comm.Def	PROG4.....(1)

SCI_B02	1-3 ALR111M Comm.Def	PROG4.....(1)
SCI_B03	1-3 ALR111M Comm.Def	PROG4.....(1)
SCI_B04	1-3 ALR111M Comm.Def	PROG4 PROG6.....(1)
SCO_B04	1-3 ALR111M Wiring-Added	PROG7.....(2)
SCO_I01	1-3 ALR111M Wiring-Changed	PROG1.....(3)
SCO_R01	2-4 ALR111M Wiring-Added Module Comm.Def	PROG1.....(4)

- Variable column

  Names of FB variables.

- Comments column

  The format of the entries in the Comments column is explained below.

  <Node Number> - <Slot Number> <Module Model> <Wiring Information> <Parameter Information>

  Wiring information (omitted if there are no changes)

  - New addition: Wiring-Added
  - Change: Wiring-Changed

  Parameter information (omitted if there are no changes)

  - Communication parameters have been changed: Comm.def
  - Module parameters have been changed: Module (*1)

  *1: For a newly added communication module, Comm.def is shown in addition to Module.

The wiring information and parameter information regarding the changes are indicated as follows:

Table C5.2.4-1 Wiring information and parameter information regarding the changes

Changes	Wiring Information	Parameter Information
A communication module has been added (when a communication definition is added and wired FB is used in the POU)	Wiring-Added	Module Comm.Def
Settings for transmission are changed.	-	-
A communication definition has been added (when wired FB is used in the POU)	Wiring-Added	Comm.Def
A communication definition is deleted.	-	-
A communication definition is changed.	-	Comm.Def
An FB has been added	Wiring-Added	- (*1)
Wiring of a FB has been changed	Wiring-Changed	- (*1)
An FB has been deleted	-	-

*1: Comm.def will be displayed if communication definition is changed.

- Used column

  The names of programs accessing the corresponding FB variables are shown. When the FB variables are subject to reading or writing, only the names of the programs using the FB are shown and the names of the FB are not shown.

Checking when the settings of SCS link transmission have been changed

The results of analysis when settings of SCS Link Transmission have been changed are displayed in the "Current Version I/O Parameter Changes Cross Reference" item of the Cross Reference Analysis Report as a dependency between the SCS Link Transmission I/O FBs whose parameters were changed and programs.

Example:

In SCS Link Transmission Builder, the variables with the following variable names are defined in Station 2.

- LTSND02001 for the first bit, LTSND02002 for the second bit of Station 2 (Self Station)
- LTRCV04001 for the first bit, LTRCV04002 for the second bit, LTRCV04003 for the third bit of Station 4 (SCS)
- LTRCV05001 for the first bit of Station 5 (SCS)
- LTFCS06001 for the first bit, LTFCS06002 for the second bit of Station 6 (FCS)
  In this case, implement the following changes.

  (1) Add wiring definition (LTSND02003) for the third bit of Station 2.

  (2) Change reception timeout of Station 4.

  (3) Change input processing at fault in wiring definition (LTRCV04002) for the second bit of Station 4.

  (4) Move wiring definition (LTRCV04003) for the third bit of Station 4 to the fourth bit.

  (5) Add definition (LTFCSXX04003) for the third bit of Station 4.

  (6) Change input processing at fault in wiring definition (LTRCV05001) for the first bit of Station 5.

  (7) Move wiring definition (LTFCS06002) for the second bit of Station 6 to the third bit.

  (8) Add Station 7 (SCS), add wiring definition LTRCV07001 and LTRCV07002 for the first bit and the second bit of Station 7.

  After (1) to (8) are implemented, the Cross Reference Analysis Report display will be as follows.

  Current Version I/O Parameter Changes Cross Reference

Variable	Comments	Used
LTSND02003	LT02-003 Wiring-Added	PROG7...(1)
LTRCV04001	LT04-001 Station	PROG4...(2)
LTRCV04002	LT04-002 Station LinkTrans.Def	PROG4...(2) + (3)
LTFCSXX04003	LT04-003 Wiring-Added Station	PROG4...(2) + (5)
LTRCV04003	LT04-004 Wiring-Changed Station	PROG4...(2) + (4)
LTRCV05001	LT05-001 LinkTrans.Def	PROG6...(6)
LTFCS06002	LT06-003 Wiring-Changed	PROG2...(7)
LTRCV07001	LT07-001 Wiring-Added Station	PROG3...(8)
LTRCV07002	LT07-002 Wiring-Added Station	PROG3...(8)

- Variable column
  Variable names of SCS Link Transmission I/O FBs

- Comments column
  The notational convention in the Comments column is explained below.

  LT<SCS Station Number (2 digits)> - <Bit Number (3 digits)><Wiring Information><Parameter Information>

  Wiring information (omitted if there are no changes)
  - New addition: Wiring-Added
  - Change: Wiring-Changed

  Parameter information (omitted if there are no changes)
  - Change of reception timeout, transmission timeout or pre-alarm set point: Station
  - Change of input processing at fault: LinkTrans.Def
  - Both: Station LinkTrans.Def

The wiring information and parameter information regarding the changes are indicated as follows:

Table C5.2.4-2 Wiring information and parameter information regarding the changes

Change	Wiring	Parameter	Remarks
Add Station	Wiring-Added	Station	Detect when wired FB is used in POU
Delete Station	-	-	Do not detect
Change Station Type	Wiring-Added	Station	Detect when wired FB is used in POU
Change Station Parameter	-	Station	Change of reception timeout, transmission timeout or pre-alarm set point
Add SCS Link Transmission I/O FB variables to Wiring Definition	Wiring-Added	-(*1)	Detect when wired FB is used in POU
		Station (*1)	Change of reception timeout, transmission timeout or pre-alarm set point
Delete SCS Link Transmission I/O FB variables from Wiring Definition	-	-	Do not detect
Move SCS Link Transmission I/O FB variables of Wiring Definition	Wiring-Changed	-(*1)	Detect when wired FB is used in POU
		Station (*1)	Change of reception timeout, transmission timeout or pre-alarm set point
Change Wiring Parameter	-	LinkTrans.Def	Change of input processing at fault
		Station LinkTrans.Def	Change of input processing at fault, reception timeout, transmission timeout or pre-alarm set point

*1: When adding a wiring, changing a wiring or changing the input processing at fault, LinkTrans.Def will be omitted.

- Used column
  Displays names of the programs accessing the variables of SCS Link Transmission I/O FBs. When accessing the SCS Link Transmission I/O FBs from FU or FB, only the names of programs using the FUs or FBs are displayed and the names of the FUs or FBs are not displayed.

Identification of programs when Inter-SCS safety communication is used

Inter-SCS safety communication is implemented using FBs for communication and binding functions. In a communication configuration, the SCS sending data is called the producing side and the SCS receiving data is referred to as the consuming side.

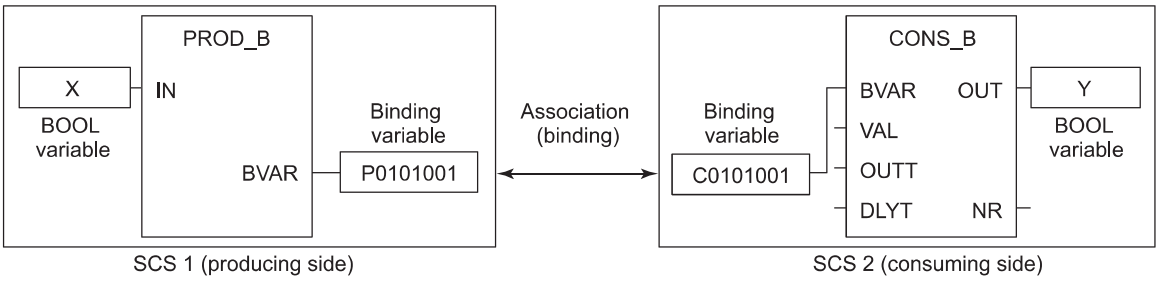

Figure C5.2.4-1 Inter-SCS communication (Example of BOOL-type variable)

The producing side and the consuming side share data using inter-SCS safety communication; they are thus dependent on each other. For this reason, if a program on the producing side has been changed, it is necessary to perform retesting or review of programs on the consuming side.

The procedure for identifying programs that may be affected is shown below.

1. Check programs displayed with red or yellow icons in Dependency Tree on the producing side.
2. Check variables for inter-SCS safety communication used in these programs.

   The "Current Version Bound Variable Usage" item of the Cross Reference Analysis Report shows binding variables used in each program. Variables starting with the letter P are variables on the producing side.
3. Check whether or not specified data has been changed for variables starting with the letter P in each program.

   If there are no changes in the specified data, the review of binding variables is finished.
4. Variables on the consuming side corresponding to binding variables whose data has been changed (variables starting with the letter P) have the same names as the binding variables, except that P is replaced with C.
5. Check the programs starting with the letter C that use the binding variables explained in step 4 in the "Current Version Bound Variable Usage" item of the Cross Reference Analysis Report.

   These programs and dependent programs are the targets of retesting or review.
6. Dependent programs are displayed in Dependency Tree by expanding the [Programs].

Current Version Bound Variable Usage

Program	Bound variables
PROG1	P0101001
PROG2	P0101002 P0101003
PROG5	
PROG6	
PROG7	P0101004
PROG8	

Figure C5.2.4-2 Current Version Bound Variable Usage of Cross Reference Analysis report (Example of producing side)

Current Version Bound Variable Cross Reference

Bound variables	Used
C0101001	PROGA
C0101002	PROGA
C0101003	PROGB
C0101004	PROGC

Figure C5.2.4-3 Current Version Bound Variable Cross-Reference item of Cross Reference Analysis report (Example of consuming side)

C5.2.5 Precautions on Cross Reference Analyzer

Cross Reference Analyzer cannot detect certain changes.

This section explains changes that are not detected by Cross Reference Analyzer and actions to be taken, and shows examples of procedures for checking such changes.

The user must check the following for SCS projects.

- Influence of input/output changes
- Change in tag name defined to allow manipulation from HIS
- Other changes not detectable by Cross Reference Analyzer

If library projects have been changed, it must be checked whether or not there are changes for the library projects as well.

Influence of input/output changes

Cross Reference Analyzer detects changes of input/output parameters and shows dependencies related to input/output variables.

However, it does not detect dependencies between inputs/outputs and system FBs that indicate input/output status.

These system FBs show the status of I/O corresponding to the node numbers, unit numbers, slot numbers and channel numbers specified for I/O variables.

Table C5.2.5-1 System Function Blocks related to inputs/outputs

Type name	Description
SYS_IOALLST	All I/O channels of SCS status indicator
SYS_NODEST	I/O channel data status indicator in FIO node
SYS_N_NODEST	All I/O channel data status indicator in N-IO node
SYS_NODEINF	FIO node status notification
SYS_N_NODEINF	N-IO node status notification
SYS_OUTST, SYS_OUTST16	FIO output module data status
SYS_N_IOST16	N-IO I/O module data status for 16 channels
SYS_INST	Detects fault in input module channels
SYS_CHST	Detects fault in channels
SYS_IOSD	Shuts down FIO output module output
SYS_N_IOSD	Shuts down N-IO I/O module output
SYS_OUTEN	FIO output module output enabled status
SYS_N_OUTEN	N-IO I/O module output enabled status
SYS_CH_OUTEN	FIO/N-IO output channel output enabled status
SYS_IOMDSP	FIO module status notification
SYS_N_IOMDSP	N-IO module status notification
SYS_ALRDSP	Outputs status of subsystem communication modules
SYS_LTSTS	SCS link transmission reception status monitor (*1)

*1: SYS_LTSTS will be affected by the setting change of SCS Link Transmission definition instead of the setting change of I/O.

If you change input/output parameters, the status of the inputs/outputs may change, which means that the output of these system FBs may change. In other words, such inputs/outputs and system FBs are dependent on each other.

Cross Reference Analyzer is unable to show dependencies between changes to input/output parameters and system FBs. If you are going to change input/output parameters, check whether or not performing such changes to input/output parameters affect other system components before downloading them to an SCS. An example of checking procedure is shown below.

1. Select a resource (SCS project) name in Dependency Tree of Cross Reference Analyzer.
2. Check "I/O Parameter Changes" displayed in the right pane of the window.

   If no input/output variables are changed, checking is finished.
3. If there are input/output variables that have been changed, check programs that use system FBs related to the inputs/outputs, and then judge whether the changes of the input/output parameters affect them. If it is judged that the FBs are affected, check the programs depending on the program in question by expanding relevant [Programs] in Dependency Tree and retest the programs depending on the program in question.

Change in tag name defined to allow for manipulation from HIS

From HIS instrument faceplates for "Override FB", "Grouping Override FB", "Password FB" and "Manual operation FB", you can change the variables in the application logic.

To allow manipulation from HIS, tag names for those FBs are set by Tag Name Builder. Even if a user changes the tag name, the change is not detected by Cross Reference Analyzer. Check whether or not tag names have been changed. Whether or not tag names have been changed can be checked by comparing the modified project data to the master database by means of Project Comparing Tool. Check can also be made by using output of self-documentation. An example of checking procedure by using output of self-documentation is shown below.

Preparation

Prepare the information before changes are made. That is, printout of the tag names of override FBs, grouping override FBs, password FBs, manual operation FBs and their corresponding internal variables (including POU names), which was printed by using the self-documentation function.

Checking procedure at online change download

1. If you change a tag name, a diagnostic information message is displayed to notify the tag name change at online change download. Check whether or not messages indicating tag name changes are displayed in the Diagnostic Information window of SCS Maintenance Support Tool.
   If no diagnostic information messages notifying tag name changes are displayed, no tag names have been changed. Checking is finished.
2. If diagnostic information messages notifying tag name changes are displayed, check that the tag names in the messages match with the intended changes.
3. Check programs of the application logic corresponding to the changed tag names in Dictionary View of SCS Manager. Test the checked program, as well as the programs that depend on the checked program. Check dependent programs by expanding the relevant [Programs] in Dependency Tree of Cross Reference Analyzer.
4. Print and store the printed documents for the next offline download.

Checking procedure at offline download

In case of offline download, compare the printed and saved list of tag names using the self-documentation function and the current status, and check the differences.

1. Display the current list of tag names in Tag Name Builder. Alternatively, print the list by using the self-documentation function.

2. Compare the current tag names with the tag names printed and saved in advance. If there are no differences, checking is finished.
3. If there are differences, check programs of the application logic corresponding to the changed tag names in Dictionary View of SCS Manager. Test the checked program, as well as the programs that depend on the checked program. Check dependent programs by expanding the relevant [Programs] in Dependency Tree of Cross Reference Analyzer.
4. Print and store the printed documents for the next offline download.

Other changes not detectable by Cross Reference Analyzer

Cross Reference Analyzer does not detect differences in items other than the definitions of the application logic. So, you need to check for changes using Project Comparing Tool or the output of self-documentation. Especially for the following definitions that are significant on safety, the user must check for changes before downloading to an SCS.

- Scan period for the application logic execution functions (defined in the Settings tab of Resources Properties in Link Architecture View)
- Use of optical ESB bus repeaters and their maximum extension distance (defined on SCS Constants Builder and I/O Parameter Builder)
- Extend scan period automatically (defined on SCS Constants Builder)
- Locking of internal variables (defined on SCS Constants Builder)
- Behavior at abnormal calculation (defined on SCS Constants Builder)
- Automatic IOM download (defined on SCS Constants Builder)
- Device Power-Off Period (defined with SCS Constants Builder)
- Device Startup Waiting Period (defined with SCS Constants Builder)
- Alarm Suppression During Device Reset (defined with SCS Constants Builder)
- Fire and gas communication startup time (defined with SCS Constants Builder)

An example of checking procedure by using the output of self-documentation is shown below.

Preparation

Prepare the information before changes are made. That is, printout of the settings of Resources Properties in Link Architecture View and definitions made on SCS Constants Builder, which was printed by using the self-documentation function.

Procedure before download

1. On SCS Manager, open Resources Properties in Link Architecture View and click the [Settings] tab. The scan period (cycle time) is shown in the tab page; so compare it with the scan period in the printout you kept to see if there is difference.
2. Open SCS Constants Builder. In the [SCS] tab page, the above mentioned definitions are shown. Compare them with those in the printout you kept and check for difference.
3. To be prepared for the next time, use the self-documentation function to print out the SCS project properties and definitions made on SCS Constants Builder and keep it.

C5.2.6 Comparison with the original project

Cross Reference Analyzer has the function to compare the work database with the master database of another SCS project, which allows you to verify that there is no difference between the regenerated SCS project and the original project.

This function eliminates the need to retest all the POUs in the case, for example, when an existing project is recreated in order to add a newly supported input/output module to it.

Place the original project at a location that is accessible by the SENG and specify it as the project to be compared; then run the analysis by Cross Reference Analyzer. You don't need to open the original project on SCS Manager or re-set the paths to the libraries.

An example of the comparison procedure is shown below.

Procedure for comparison with the original project

From the [Analyze] menu of the Cross Reference Analyzer, select [Compare with Original Project]. When Compare with Original Project starts up, a dialog box appears, prompting you to specify the top path to the SCS project which you want to compare. Specifying the path to the SCS project and clicking [OK] starts the comparison. The work database of the project you are working with on SCS Manager is compared with the master database of the project you have specified.

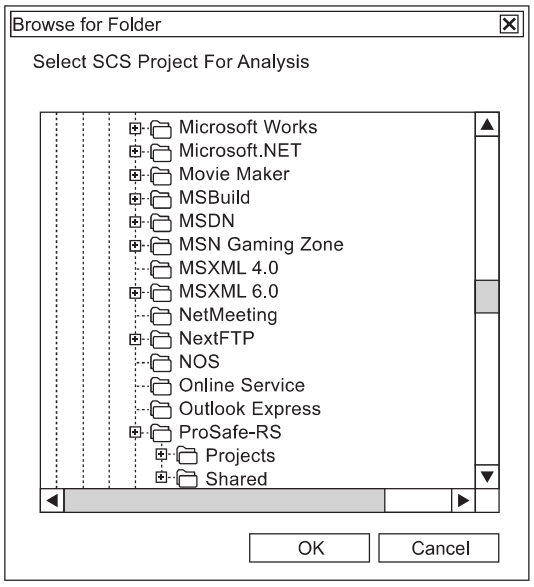

Figure C5.2.6-1 Dialog box for selecting the path to the original project

However, note that the comparison is performed only when the target names (SCS_TARGET/SCS_SIMULATOR) match between the project you are working with on SCS Manager and the project specified for comparison. If the target names do not match, Cross Reference Analyzer regards it as an error and the analysis fails. When all POUs have been acknowledged through comparison with the original project, you can download the project to an SCS. After downloading is completed, if you display the analysis results using the previous analysis result displaying function of Cross Reference Analyzer, the results of comparison with the original project will be shown.

Indication on Cross Reference Analyzer

If you have run the analysis by using the [Compare with Original Project] command, the indication on the Cross Reference Analyzer window and the printout of the analysis report will be as shown below. You can identify the original project that is used for comparison from these indications.

- Path to the original project is shown on the title bar.

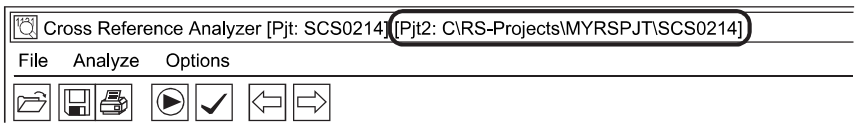

Figure C5.2.6-2 Title bar

- Path to the original project is printed in the report

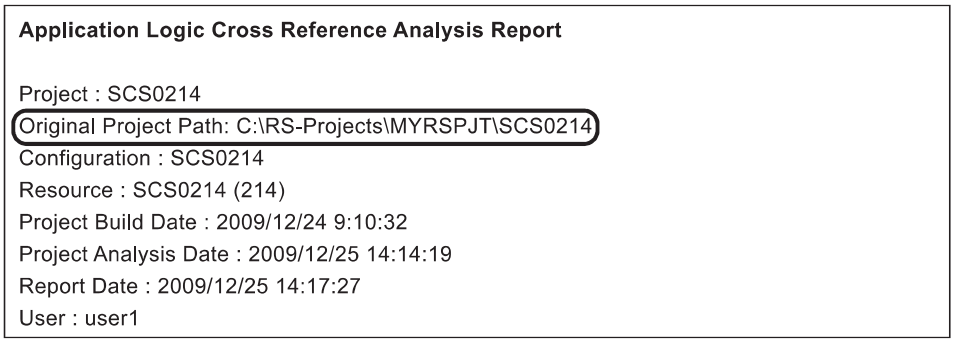

Figure C5.2.6-3 Report

Notes on comparison

If you add or delete programs after you creating a new project and importing data to it, all the programs following the added or deleted program will be regarded as changed programs during comparison with other project. When you create a new project and import data to it, use Cross Reference Analyzer to compare the created project with the original project and download it to the SCS before you make any further changes.

Checking the regenerated project

Use Cross Reference Analyzer to verify the equivalence between the regenerated project and the original project. For the data that cannot be verified by Cross Reference Analyzer, you need to check that the regenerated SCS project and the original SCS project are the same by means of Project Comparing Tool. If you have made further changes to the regenerated project, perform checking using Cross Reference Analyzer and self-documentation output to make sure the range of retesting, as should be done with the earlier revisions.

SEE ALSO For more information about procedures for checking a regenerated project and the definition items of the project that need to be checked, refer to:

- E3.3, “Data transfer procedure during SCS project regeneration” on page E3-9
- C5.2.5, “Precautions on Cross Reference Analyzer” on page C5-46

C6. Simulation tests

Applications should be tested in the simulator running on SENG by using the logic simulation test or the SCS simulation test. When running an SCS simulation test on SCS projects with Current Project attribute, create an SCS project for testing by using the Test Project Creation Tool as preparation for the test. Register the SCS project for testing in an AD project for testing.

Application logic can be debugged with the Application Debug Function, Forcing of I/O variable and Online Monitoring Function. In the logic simulation test or the SCS simulation test, I/O channels are equivalent to being locked all the time. In the logic simulation test or the SCS simulation test, connect iDefine by using the iDefine Test Manager and you can use the iDefine test functions to test the parts created in iDefine.

SEE ALSO

For more information about logic simulator test operations, refer to:

2., “Logic simulation test operations” in Test Function Guide (IM 32P04B30-01EN)

For more information about preparing and running SCS simulation tests, refer to:

3., “SCS simulation tests” in Test Function Guide (IM 32P04B30-01EN)

For more information about the operations for using iDefine in simulation tests, refer to:

6., “Using iDefine in tests” in Test Function Guide (IM 32P04B30-01EN)

C7. Offline download to the target SCS

During offline download, the SCS database, which contains all the information required for operation of an SCS, is transmitted from the SENG to the SCS; meanwhile, the SCS functions are stopped. The SCS database is downloaded via the control bus and stored in the flash memory of the SCS and the non-volatile memory of input/output modules. The SCS database downloaded to the SCS is saved as the master database together with the source files in the SENG.

Downloaded items

- SCS system programs
- Application database
  The application database created by the Safety application definition function and CENTUM integration function is downloaded to the CPU module.
- I/O configuration information
  The parts of the database created by the I/O definition function related to input/output modules are downloaded to the input/output modules.

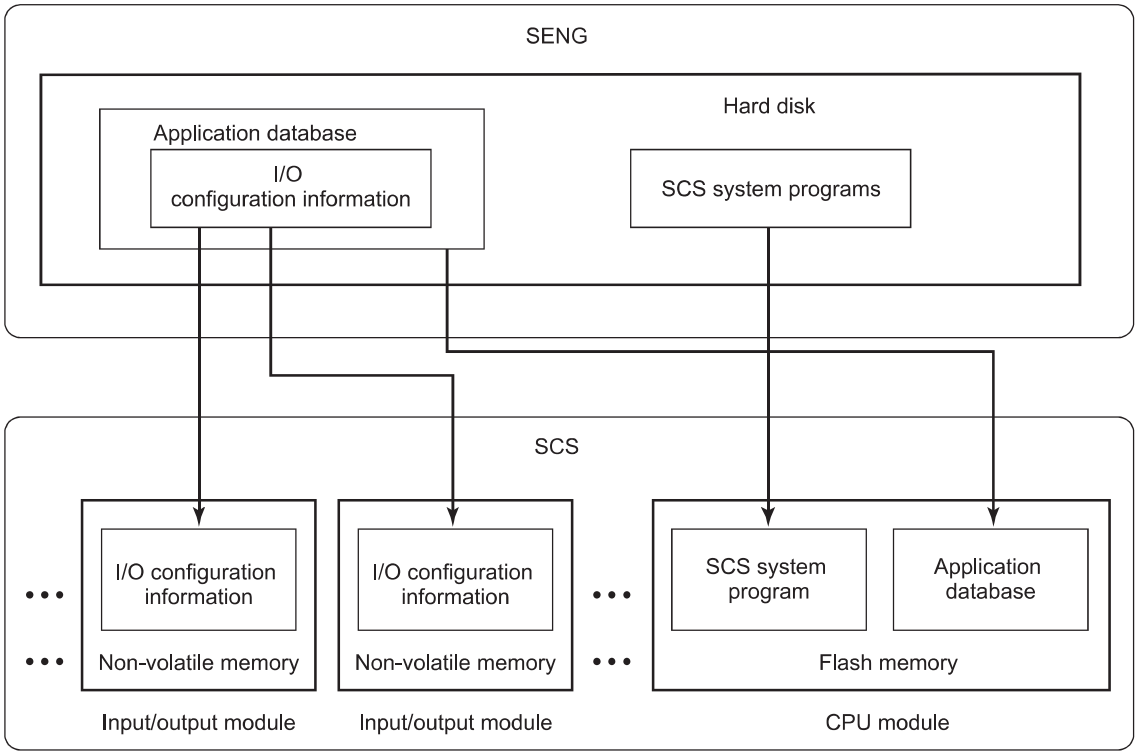

Figure C7-1 Offline download

CAUTION

The following operations are performed if you run offline download. Actions to prevent false trip are required before running offline download.

- Functions running on the SCS stop, and all the output modules output the fail-safe values that are specified in I/O parameters.
- Inter-SCS safety communication is disconnected.
- The forcing function is cancelled.
- Override from the HIS is cancelled.
- Break points set by the target test function are cancelled.
- SOEs and diagnostic information collected so far in the SCS are deleted (they are saved in the NVRAM (nonvolatile RAM)).
- Password for changing the SCS security level is deleted.

Procedure for offline download

This section describes procedures from building an application logic to performing offline download.

IMPORTANT

Perform Clean Project in a timely manner; specifically, before FAT (Factory acceptance tests) or SAT (Site acceptance tests). Before you execute offline download, we recommend you perform Clean Project.

SEE ALSO For more information about clean project, refer to:

"Cleaning Projects" in "Build" in "Code Generator" in "Workbench" in the Workbench User's Guide

What to do before offline download

Build the application logic and analyze it by using Integrity Analyzer and Cross Reference Analyzer.

TIP The items that may require retesting but not detected by Cross Reference Analyzer must be checked by the user.

IMPORTANT

Call up the SCS Information dialog box and confirm that the number of logical I/O points in use does not exceed the number of assigned I/O licenses.

If the target SCS is running, set the SCS security level to Level 0 by using the SCS Security Level Management Function.

Start the offline download

1. From the [Debug] menu of SCS Manager, select [Download].

On the CENTUM Integration, a dialog box asking you if you want to save Operation Mark or not appears.

2. Save Operation Mark if necessary.

TIP

- If Integrity Analyzer or Cross Reference Analyzer has already been launched when you start offline download, a message prompting to close the analyzer is notified and the download ends with an error.
- If the SCS security level is Level 1 or Level 2 when you start offline download, a message prompting to set Level 0 is notified and the download ends with an error. Set the SCS security level to "0" and start offline-downloading.
- If the I/O Lock window or Inter-SCS Communication Lock window is left open when you start offline download, an error message appears and the download processing ends.

3. A dialog box asking you if you are sure to start an offline download appears. Click [OK]. A dialog box for setting a password for changing the SCS security level appears. After that, a dialog box prompting you to manage versions of the SCS project appears. When an offline download completes, SCS is restarted. The SCS database offline downloaded to the SCS is automatically stored in SENG as a master database together with source files.
4. On the CENTUM Integration, download the database of the CENTUM project also.

Dealing with the offline download confirmation dialog box

The system checks to see if there is a possibility that the online change variables area in the database has been used before executing the offline download. If the online change variables area is used, a confirmation dialog box appears. This situation can be solved by performing a clean project and a build.
In the confirmation dialog box, select [Cancel] to terminate the offline download processing. Perform a clean project and a build, and then execute offline download. The offline download starts when you click [OK] in the confirmation dialog box.

Offline download process in I/O list engineering

When you execute an offline download of an SCS project that was created with I/O list engineering, the status of the safety I/O list, safety communication I/O list, and the IOM information are checked. More specifically, whether the safety I/O list, safety communication I/O list, and IOM information were edited after the builds by Generation Manager succeeded is checked. If it corresponds to the check items, an error occurs and the offline download stops.

If the safety I/O list, safety communication I/O list, and IOM information cannot be checked due to disrupted communication with the AD Server, a warning will appear but you will still be able to download the project. After the connection with the AD Server is restored, the system will check whether any offline download was run during the connection interruption if either of the following measures is taken:

- Use the System Structure Navigator in AD Organizer and execute the update function of the Revision History Utility.
- Use SCS Manager to open the SCS project.

If an offline download is performed during the connection interruption, a warning appears when the corresponding SCS project is opened in SCS Manager. This warning will disappear if the build and download are performed.

When the offline download succeeds, labels are set to the safety I/O list, safety communication I/O list, and IOM information. The label represents a character string as mentioned below.

```
SCS Project Name-Download-Date and Time
```

End the offline download

Set the passwords used when changing the SCS security level.

Manage the operation history by using the operation history management utility of AD Organizer. Check-in the SCS project with the Version Control Tool.

SEE ALSO For more information about the operation history management utility of AD Organizer, refer to:

C2.6, “Operations of the revision history function” in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about the version control tool, refer to:

F5., “Version control” in Engineer's Reference Manual (IM 32P04B10-01EN)

Security of SCS

SCS security levels provide adequate security through specifying the passwords. Passwords for different security levels can be set for each SCS.

- Setting and changing passwords
- Changing SCS security levels

Note that it is necessary to return the SCS security level to Level 2 before closing an SCS project.

This section describes how to set passwords for changing SCS security levels and how to change the levels.

IMPORTANT

No password has been set after executing offline download and master database offline download. Make sure to set passwords again.

TIP The access to SCS is controlled by SCS itself according to its security level. Operations on the SENG is not be prohibited according to the SCS security level, however.

How to set and change passwords

The password that is used to change the SCS security level is stored within the SCS. This password can be set or changed from the Set SCS Security Level dialog box.

IMPORTANT

No password has been set after executing offline download and master database offline download. Make sure to set a password at this stage.

1. Select [Maintenance] from the [Tools] menu of SCS Manager.
   The Maintenance Launcher menu appears.
2. Select [Set SCS Security Level] from the Maintenance Launcher menu.
   The Set SCS Security Level dialog box appears.

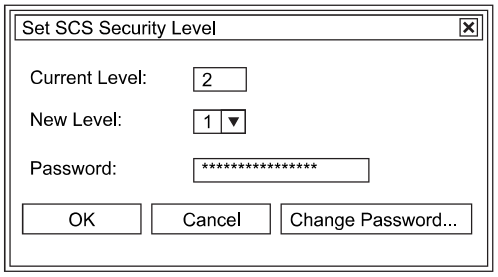

Figure C7-2 Set SCS Security Level dialog box

3. Click the [Change Password] button.
   The Change SCS Security Level Password dialog box appears.

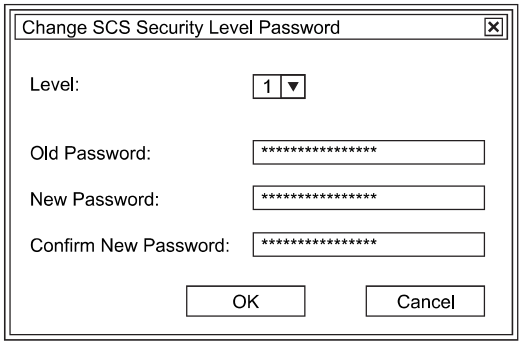

Figure C7-3 Change SCS Security Level Password dialog box

4. Select the security level for which you set a password in [Level:].
   It is necessary to set one password for changing to Level 1 and one for Level 0, respectively.
5. Enter the current password in the [Old Password:] field.
6. Enter a new password in the [New Password:] field, and once again in the [Confirm New Password:] field.
   The passwords you have entered appear as a series of asterisks (*).

   A password is a maximum 16 of single-byte alphanumeric characters and following symbols including a space character. The password is case-sensitive.

   ! " # $ % & ' ( ) * + , - . / : ; < = > ? @ [¥] ^ _ ` { | } ~

   You do not need to enter [Old Password:] if you have not set any password before, or if you have just executed an offline download or a master database offline download.
7. Click the [OK] button.
   The confirmation dialog box appears.

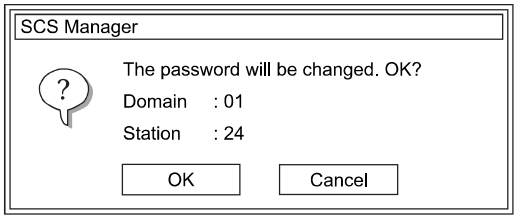

Figure C7-4 Confirmation dialog box

8. Click the [OK] button.
   Both new and old passwords will be sent to SCS. If the password is successfully changed, the dialog box notifying the success appears. The new password becomes valid. If the password change fails, a dialog box will be displayed to notify the failure.

How to change SCS security levels

The SCS security level can be changed in the Set SCS Security Level dialog box of SCS Manager.
The table below shows the combinations of levels for which security level changes are allowed via operations on the Set SCS Security Level dialog box.

Table C7-1 Security levels that can be changed through operations in the Set SCS Security Level dialog box

Current SCS security level	New SCS security level (*1)		
	Level 2	Level 1	Level 0
Level 2	-	Yes (*2)	Yes (*2)
Level 1	Yes (*2)	-	Yes (*2)
Level 0	Yes(*3)	No	-

*1: Yes: The security level can be changed.
No: The security level cannot be changed.
*2: The security level can be changed to the target SCS security level.
*3: Security level changes can be made only in SCS simulator.

To change the security level, you need to enter the password. However, you don't need to enter a password when changing the security level from Level 1 to Level 2.

You cannot raise the security level from Level 0 to Level 2 from the Set SCS Security Level dialog box. In SCS Simulator of SCS Test Functions, however, you can raise from Level 0 to Level 2 on the Set SCS Security Level dialog box. This operation does not require a password.

CAUTION

To set the SCS security level back to Level 2 after changing to Level 0, you must restart the SCS, execute offline download, or execute master database offline download. In particular, be sure to execute offline download if you used break points in debugging of the application logic.

These operations require stopping of the system. When you change the security level to Level 0, do so very carefully considering the consequences of the system stop.

The SCS security level can be changed in the following procedure.

1. In SCS Manager, open an SCS project whose security level you want to change.
2. Select [Maintenance] from the [Tools] menu of SCS Manager.
   The Maintenance Launcher menu appears.
3. Select [Set SCS Security Level] from the Maintenance Launcher menu.
   The Set SCS Security Level dialog box appears. The current security level is displayed in [Current Level:]; this item is display only and cannot be changed.

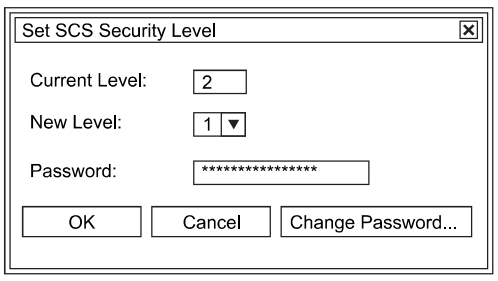

Figure C7-5 Set SCS Security Level dialog box

4. Select the security level you want in [New Level:] and enter the password for the level you want in [Password:] text box.
   All characters you enter are displayed as asterisks (*).

5. Click the [OK] button.
   The confirmation dialog box appears.

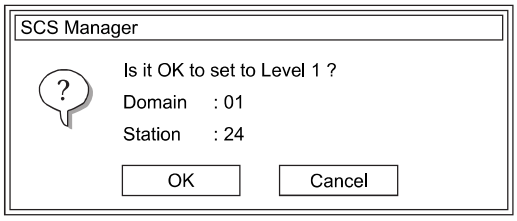

Figure C7-6 Confirmation dialog box (when changing to Level 1 or Level 2)

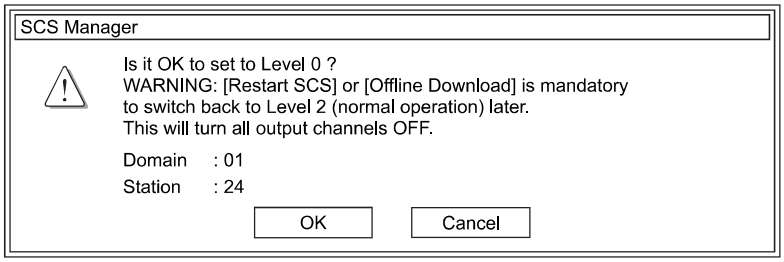

Figure C7-7 Confirmation dialog box (when changing to Level 0)

6. Click the [OK] button.
   When changing the security level to Level 0, the following dialog box appears to confirm the change again. When you set the level back to Level 2 from Level 0, the system stops. Confirm that this does not cause any problems. To proceed with the change, click [OK].

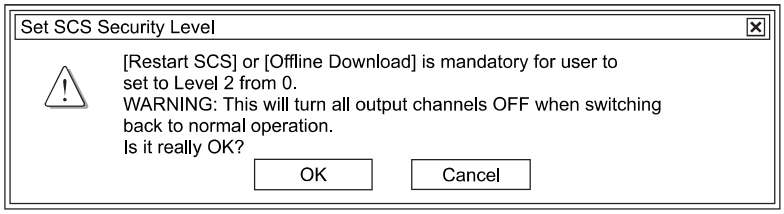

Figure C7-8 Dialog box confirming change to Level 0

If the security level of SCS is changed, the message showing the result of change is displayed.

The error message is displayed if the security level could not be changed.

Confirming the SCS security level reset by SCS Manager

If the security level of SCS project currently opened in SCS Manager is not Level 2, the confirmation dialog box prompting to reset the security level to Level 2 appears when closing it.

IMPORTANT

This dialog box is for confirmation only. Open the corresponding SCS project again and change the security level using the Set SCS Security Level dialog box.

The confirmation dialog box appears in the following timings.

- When closing an SCS project by exiting SCS Manager

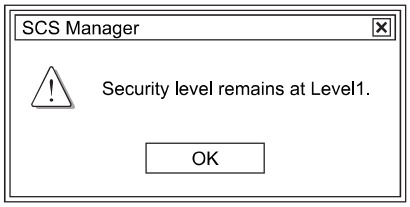

Figure C7-9 Example of Confirmation dialog box (when closing by exiting SCS Manager)

Clicking the [OK] button to exit SCS Manager leaves the security level unchanged.

- When closing an SCS project by opening another SCS project

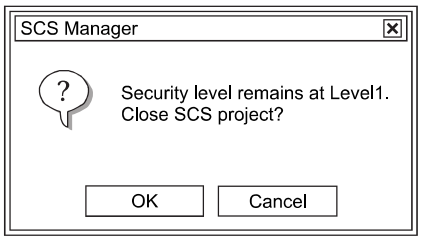

Figure C7-10 Example of Confirmation dialog box (when closing by opening another SCS project)

Click the [OK] button to close the currently opened SCS project without changing its security level, and then open another SCS project.

Click the [Cancel] button to keep the currently opened SCS project opened, and another SCS project will not open.

C8. Output enable operation

How to enable the outputs, the detailed procedure and how to start the output module will be explained in this section.

TIP

In this document, I/O shutoff switch and DO shutoff switch of the universal type I/O module are referred to as an output shutoff switch.

Overview on Output enable operation

When the operating mode of SCS is Waiting mode, some output channels are in Output Disable status, so that they cannot output the application logic results. Moreover, after SCS is started, the inter-SCS safety communication cannot send data to consumer side, the SCS Link Transmission and the subsystem communication cannot function either.

The Output Enable Operation will enable the output channels to output the application logic results, will start the inter-SCS safety communication, the SCS link transmission and the subsystem communications.

Output Enable operation can be performed for the whole SCS only. The output channel cannot be specified individually. Therefore, you cannot enable only one of the inter-SCS safety communication, SCS Link Transmission or subsystem communication.

Enabling output

Click the [Output enabled] button in the I/O Channel Status dialog box; the processing result of the application logic is output to the field and the SCS operating mode changes to the Running mode. Note that all nodes, all output modules and all channels must be in normal status in order for the SCS to be changed to the Running mode. If there is any error, the status does not change even if you perform the Output Enable Operation.

SEE ALSO

For more information about I/O Channel Status dialog box, refer to:

H4., “Displaying I/O channel status” on page H4-1

Start output module operation

If an error serious enough to activate the Output Shutoff switch occurs, there is a case where the output module stops its output and waits for the Output Module Start depending on an error cause. Perform the Start Output Module operation to start the output modules whose output is stopped.

The Start Output Module operation is performed individually. It can be performed regardless of the SCS security level.

The SCS continues to be in the Waiting mode even after the Start Output Module operation is completed. The channel in the Output Disable status will not change to Output Enable, either. Perform the Output Enable operation to change channels in the output disabled state to the output enabled state.

Note that this Start Output Module operation does not influence the output modules of which the Output Shutoff switch has not been actuated.

1. Select the output module whose output is stopped in Hardware Configuration Tree View of the SCS State Management window. Click [Start output module] button on the toolbar. After this is confirmed using the Confirmation dialog box, the selected output module starts up. The output from all channels will continue to be "0" even after the output module starts up.
2. Perform the output enable operation.

The output module is connected to the output of application logic and the result of the application logic is output from the module.

Enable Output operation

- Each output channel of SCS has two statuses, Enabled Output and Output Disabled, when the output is disabled, the output from application logic is not connected to the actual output channel, and OFF or pre-specified fail safe value is output to the field. Perform the Enable Output Operation to connect the output values from the application logic to the output channels. All normal outputs (DO module channels, AO module channels, Subsystem Communication output) are enabled by the output enable operation from an SENG.

  When SCS starts, all output channels are in the output disabled status.

- Transmission is started in the inter-SCS safety communication and subsystem communication output by the first output enable operation after SCS startup.

- When an output module fails, all output channels on the output module enter the output disabled status.
  When an output channel fails, the output channel enters the output disabled status.

- In the case of subsystem communication, it does not result in the output disabled status even if an error occurs in the subsystem communication (communication module error or communication error).

- The output enable operation can be performed from the application logic using a system function block. There are two types of function blocks that can perform the output enable operation: SYS_STAT, which enables safety outputs and outputs in inter-SCS safety communication, and SYS_STAT_SC, which enables subsystem communication outputs. Use these system function blocks and perform the output enable operation if it is desired to have different output start timings for output modules and the subsystem communication.

SEE ALSO For more information about specifications of SYS_STAT, refer to:

11.1, “SYS_STAT (SCS status management)” in POU Reference Manual (IM 32P03B20-01EN)

For more information about specifications of SYS_STAT_SC, refer to:

12.13, “SYS_STAT_SC (subsystem communication output status indicator)” in POU Reference Manual (IM 32P03B20-01EN)

C9. Target tests

In a target test, the application logic is tested on the actual SCS. SCS Manager is used to perform test operations and display the statuses and the results. Testing by overriding from HIS is performed in an environment where ProSafe-RS is integrated with CENTUM. The target test function of CENTUM can be used as necessary. For the parts that were created by using iDefine, connect iDefine and SCS through the iDefine Test Manager in AD Organizer and run the test using the iDefine test function.

IMPORTANT

Target tests are mandatory for ProSafe-RS. The user must test the application in target tests at the final stage.

To use all the functions provided in the test function instead of simply monitoring, set the SCS security level to Level 0. The same applies when using the iDefine test function.

- Application logic can be debugged with the Application Debug Function, Forcing of I/O variable and Online Monitoring Function.
- Application can be executed without mounting I/O modules or wiring field devices when the Forcing Function for the I/O modules is used.
- Application logic can be debugged using the Forcing Function for I/O variables by changing conditions of the application logic.

By using the target hardware, perform tests on all signal paths and logics (FU/FB).

SEE ALSO

For more information about target test operations, refer to:

4., “Target tests” in Test Function Guide (IM 32P04B30-01EN)

For more information about the operations for using iDefine in target tests, refer to:

6.4, “Using iDefine in target tests” in Test Function Guide (IM 32P04B30-01EN)

D. Procedures to create applications using the I/O list engineering method

This part gives an overview of the procedures of AD Organizer when using I/O list engineering and the procedures when using iDefine.

The safety I/O list and safety communication I/O list are used in the engineering process. Acquire the safety I/O list and safety communication I/O list from the customer or create a new one.

The user can use the safety I/O list to make definitions based on the P&ID tag name in the application, and proceed to build the application without having to wait for the detailed design of the I/O module or the data communication. By using a safety communication I/O list, you can define communication modules and proceed with building the application.

In the Safety I/O Editor, you can import and edit the safety I/O list that you have prepared in advance or create a new safety I/O list.

In the Safety Communication I/O Editor, you can import and edit the safety communication I/O list that you have prepared in advance or create a new safety communication I/O list.

In the IOM Definition Editor, you can assign SCS nodes and input/output modules.

The changes made in AD Organizer editors can be reflected in SCS projects by using Generation Manager.

With I/O list engineering, you can also use iDefine to create application logics.

Create an application logic by using iDefine based on the IOM information that was defined in AD Organizer and reflect the application logic in SCS by using AD Organizer.

SEE ALSO For more information about Generation Manager, refer to:

D4., “Overview of RS generation” on page D4-1

D1. Engineering based on the safety I/O list

In I/O list engineering, you can create and edit safety I/O lists by using AD Organizer.

The engineering data is reflected in the SCS project by using the RS Generation Manager of AD Organizer.

D1.1 Overview of I/O list engineering

You can create a safety I/O list based on the I/O information list, containing information about AIO, DIO, and so on, that is obtained from the plant designer.

A safety I/O list is created by defining safety I/O in the Safety I/O Editor and then importing the I/O information list. In the Safety I/O Editor, one row is displayed for each I/O point, showing the information that identifies whether it is input or output.

Follow these steps to create a safety I/O list:

1. Start up the Safety I/O Editor.
2. Import the I/O information list to the safety I/O list.
   When imported, the setting items in the I/O information list, which is provided in Microsoft Excel.xlsx format, are mapped to the setting items of the safety I/O list. You can save and reuse the mapping information.
3. Define I/O module assignments.
   By using the grid rule function, you can perform a bulk edit and detailed check of the I/O module assignment information.

   For use in the grid rule function, setting items that users can freely define as reference information are provided. These setting items are called User Define.
4. Compare the I/O information lists before and after the import and reflect the differences to the existing data.

TIP

You can export the safety I/O list file. The exported file is in the Microsoft Excel.xlsx format.

5. Check the I/O module assignment results.
   The following information appears:
   - IOM configuration
   - Details of safety I/O connection for each IOM
6. Save and check in the safety I/O list.
7. When engineering by using iDefine, export the safety I/O list and IOM definition data for iDefine.

SEE ALSO

For more information about the procedures to export files for iDefine from AD Organizer, refer to:

D5.2.1, “Exporting the ProSafe-RS I/O file from AD Organizer” on page D5-9

D1.2 Creating a new safety I/O list

Follow these steps to create a new safety I/O list:

1. Select the I/O-List folder of the System Structure Navigator.
2. From the context menu, select [New Safety I/O List].
   The newly created safety I/O list is displayed in the System Structure Navigator in edit mode.
3. Enter unique safety I/O list name.
   The safety I/O list name that is entered is referred to as the P&ID group.

   A new safety I/O list is created. Once it is newly created, it is automatically checked in to the server.

Folder location of the safety I/O list definition

When RS project, SCS project, node, slot, and terminal numbers have not yet been defined, safety I/O lists are defined as the files under the I/O-List folder. Once these are defined, the safety I/O lists are copied to the I/O_definition folder under the N-IO folder or FIO folder of each SCS.

After the definition of the safety I/O list has been copied, you can select the safety I/O list from under the FIO or N-IO folder of SCS and start Safety I/O Editor from the context menu. Only the contents that are defined in the corresponding file are shown in each editor.

D1.3 Operating a safety I/O list

This section describes how to rename and delete a safety I/O list.

Changing the name of the safety I/O list

Follow these steps to change the name of the safety I/O list:

1. Right-click on the safety I/O list in the System Structure Navigator and select [Rename]. The P&ID group of the safety I/O list name appears in the edit status.
2. Enter a new P&ID group. The name of the safety I/O list changes.

Deleting the safety I/O list

You need to delete the safety I/O list after deleting all I/O information that is assigned to the I/O module. Follow these steps to delete the safety I/O list:

- Select the safety I/O list to delete using System Structure Navigator and click [Delete] on the tool bar of AD Organizer.

TIP

- When the Safety I/O Editor is started, the safety I/O list cannot be deleted.
- You can delete only one safety I/O list at a time.

D1.4 Defining I/O information by using Safety I/O Editor

This section describes how to use Safety I/O Editor to edit a safety I/O list.

D1.4.1 Starting the Safety I/O Editor

You can start the Safety I/O Editor from the System Structure Navigator in AD Organizer. The modes of the Safety I/O Editor are edit mode, revision history mode and read-only mode.

You can open two windows simultaneously with the following combination:

- Edit mode and read-only mode
- Revision history mode and read-only mode

You cannot open two windows with the combination of edit mode and revision history mode.

Starting the Safety I/O Editor for editing

Depending on the operation purpose, the startup method of the Safety I/O Editor varies.

IMPORTANT

To edit I/O information for each SCS, you can start the Safety I/O Editor after setting the station configuration and defining the I/O module assignment information in the safety I/O list.

- Perform one of the following operations using the System Structure Navigator to start the Safety I/O Editor:
  - When editing I/O information for each P&ID group
    Select and double-click the safety I/O list in the [I/O-List] folder.
  - When editing I/O information for each applicable RS project
    Right-click the RS project and select [Open] > [Safety I/O Editor].
  - When editing I/O information for each applicable SCS
    Right-click the target SCS and select [Safety I/O Editor].
  - When editing I/O information for each applicable module
    Double click the [I/O definition] under the applicable module folder.

  The Safety I/O Editor appears in the document window area.

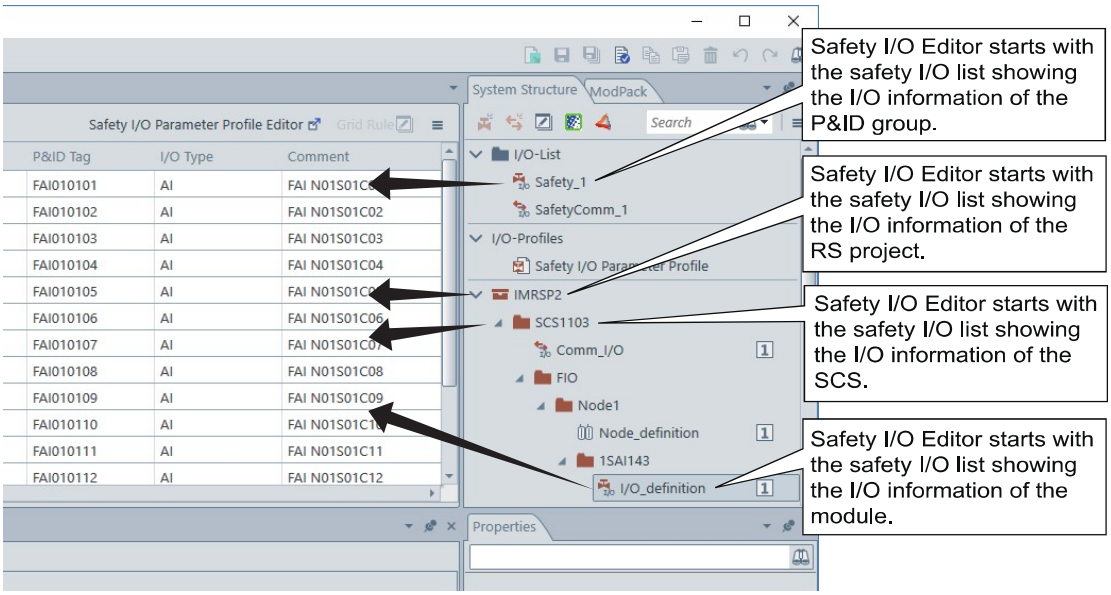

Figure D1.4.1-1 Safety I/O Editor

TIP

When the Safety I/O Editor is started, the source for which you have started the editor appears in the window title.

Starting the Safety I/O Editor for read-only

Depending on the operation purpose, the startup method of the Safety I/O Editor varies.

- Perform one of the following operations using the System Structure Navigator to start the Safety I/O Editor in read-only mode:
  - When reading definitions for each P&ID group
    Right-click the safety I/O list in the [I/O-List] folder and select [Open (Read-Only)].
  - When reading definitions for each applicable RS project
    Right-click the RS project and select [Open (Read-Only)] > [Safety I/O Editor].
  - When reading definitions for each applicable SCS
    Right-click the target SCS and select [Safety I/O Editor (Read-Only)].
  - When reading definitions for each applicable module
    Right-click the [I/O definition] under the applicable module folder and select [Open (Read-Only)].

  The Safety I/O Editor appears in the document window area in read-only mode.

TIP

If content is being edited in the edit mode editor, the contents being edited are also reflected in the read-only mode editor. However, the update is manual.

Switching the display of the safety I/O list

You can switch the display of the safety I/O list for each I/O type. You need to perform one of the following operations to switch the display.

- To display all I/O and setting items
  From the drop-down list on the left side of the toolbar in the Safety I/O Editor, select [All].
- To display only analog I/O and related setting items
  From the drop-down list on the left side of the toolbar in the Safety I/O Editor, select [AIO].
- To display only discrete I/O and related setting items
  From the drop-down list on the left side of the toolbar in the Safety I/O Editor, select [DIO].

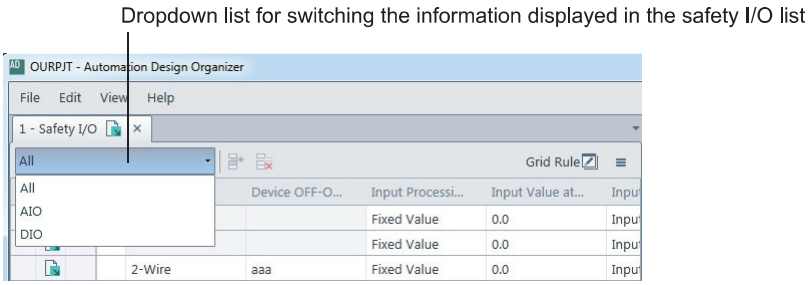

Figure D1.4.1-2 Switching the display of the safety I/O list

Setting items of the Safety I/O Editor

The following table shows the setting items of the Safety I/O Editor.

Table D1.4.1-1 List of setting items of the Safety I/O Editor

Category	Column name	Description	Mandatory setting or not (*1)	SCS Manager item where the setting is reflected through RS Generation
For I/O list management	Area	Area name	-	-
	P&ID Sheet	P&ID sheet name	-	-
I/O list common	P&ID Tag	P&ID tag name Key information required to identify each I/O The P&ID tag must be unique within the P&ID group.	1	I/O Parameter Builder P&ID tag name (*2)
	I/O Type	I/O type. Select from the following AI, AO, DI, DO	1	-
	Comment	Variable comment of the IO variable that is defined in Dictionary	-	Variable in Dictionary Variable comment
	Range LO	Scale low limit	-	-
	Range HI	Scale high limit	-	-
	Eng Unit	Engineering unit	-	-
	I/O Tag	IO Variable Name Normally, set the same name as the P&ID tag, or an abbreviated name. Defined in Dictionary View and assigned to each channel on the I/O Wiring View The I/O tag must be unique within the SCS.	1	Variable in Dictionary Variable name I/O Wiring View
	Variable Group	Variable Group	-	Dictionary View

*1: Whether column settings are required or not are indicated in the following categories:
- 1: Always set
- 2: Set after assigning the I/O to SCS and IOM
- 3: Configuration is required after assigning the I/O to SCS and IOM
- -: Setting not required

*2: For FIO, up to 16 single-byte characters. For N-IO, up to 32 single-byte characters. Characters that exceed the limit are truncated during the reflection process.

*3: For N-IO, 2
For other than N-IO, -

*4: For DO module of FIO, it is reflected to Output Value in Detecting Error.

D1.4.2 Importing the I/O information list

You need to prepare the I/O information in Microsoft Excel xlsx format. Follow these steps to import the I/O information:

1. Select the Sub menu button from the Safety I/O Editor, and select Import.
   The Import wizard appears.
2. In the File box, specify the Microsoft Excel file in xlsx format of the I/O information to be imported.
   Sheet Name shows the sheet name of the I/O information list, Header Row Position shows the first row number, and Target P&ID Group shows the P&ID group that is included in the I/O information list.

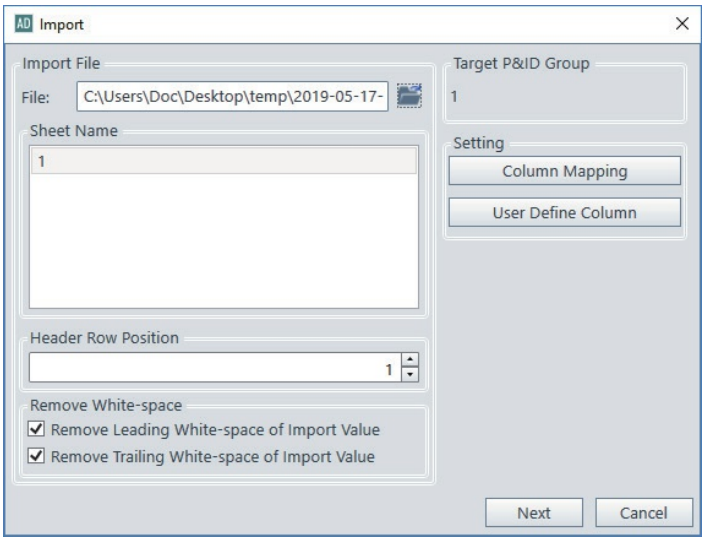

Figure D1.4.2-1 Import wizard

3. Select the sheet to be imported in Sheet Name.
4. Enter the row number in which the setting item name is entered in Header Row Position.
5. Set the following details in Settings if necessary.
   More specific instructions are given later.
   - If the setting item of the I/O information list to be imported does not match the setting item of the safety I/O list, click the [Column Mapping] button to map the setting items.
   - If the setting item of the I/O information list to be imported cannot be mapped to the setting item of the safety I/O list, click the [User Define Column] button, and after adding the new setting item to the safety I/O list, perform the mapping to these new items.
6. Select the [Remove Leading White-space of Import Value] check box or the [Remove Trailing White-space of Import Value] check box optionally.
7. Click [Next].
   The screen will switch to the Comparison and Setting screen.
8. Select either [All Check (Add/Update/Delete)] or [Part Check (Add/Update)].
   All the rows in the list of I/O information are imported.

   If you have selected [All Check (Add/Update/Delete)], the rows that are not available in the I/O information list are deleted from the safety I/O list.

   If you have selected [Part Check (Add/Delete)], the rows that are not available in the I/O information list are not deleted from the safety I/O list.
9. Click [Finish].
   The I/O information list is imported, and the safety I/O list is checked out.

Mapping the setting items of the I/O information list to the setting items of the safety I/O list

The operations for mapping are the same with safety communication I/O lists. When mapping setting items of a safety communication I/O list, replace safety I/O list with safety communication I/O list.

To import the I/O information list, not all of the setting item names may necessarily match. Thus, it is necessary to map the setting items of the I/O information list so that they match the setting items of the safety I/O list. Follow these steps to perform mapping:

1. In the Import wizard, click [Column Mapping].
   The Column Mapping dialog box appears. The setting items that do not match the setting items of the safety I/O list are displayed in [Unmapped], while the setting items that match are displayed in [Mapped]. [Client] shows the setting items of the I/O information list, while [AD Suite] shows the setting items of the safety I/O list.

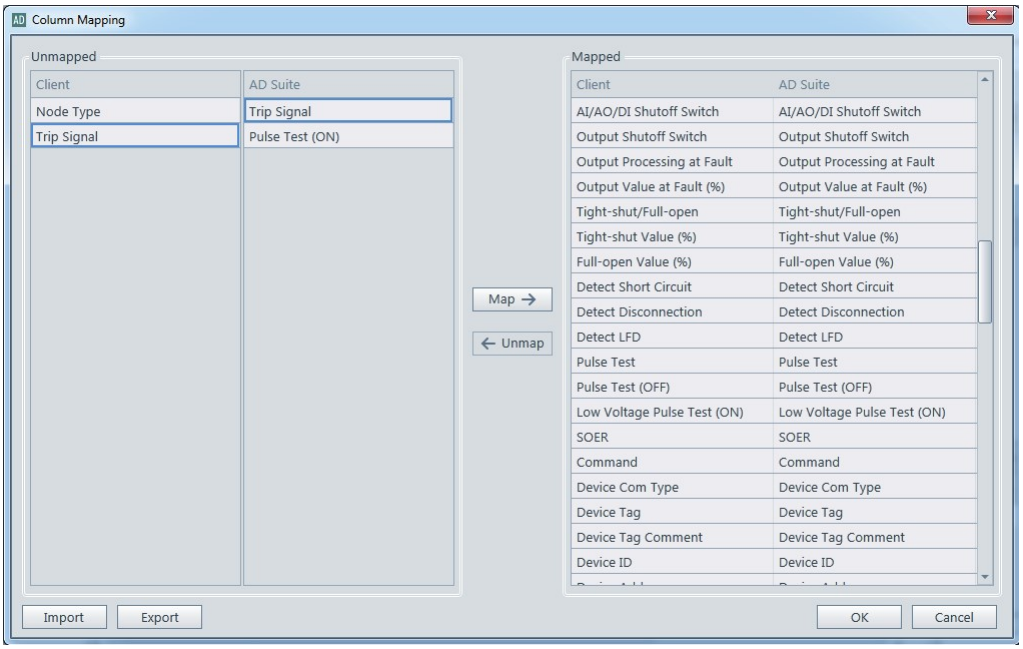

Figure D1.4.2-2 Column Mapping dialog box

2. In [Unmapped], select the setting items of the I/O information list and the setting items of the safety I/O list that are to be mapped.
3. Click the [Map] button.
   The setting items of the I/O information list and the setting items of the safety I/O list are mapped and displayed in [Mapped].
4. Click the [OK] button.
   The mapping information is created.
5. Click the [Next] button in the Import wizard.
   The I/O information list is imported based on the mapping information.

TIP

You can export the mapping information to a Microsoft Excel xlsx format file. You can also import the exported file and map the setting items based on this information.

Modifying the mapping information in AD Organizer that has been upgraded to version R4.05 or later

To import the I/O information list that was created using a version earlier than R4.05 to the safety I/O list and safety communication I/O list, modify the column mapping information of user-defined columns as necessary.

For example, if you have created Typical as an alias name in a user-defined column, open the Column Mapping dialog box when importing and follow these steps to modify the settings so that the data is imported to the standard column (Typical):

1. In the Mapped area, select the row that includes the upgraded column name (_Typical).
2. Click [Unmap].
   The pair is moved to the Unmapped area.
3. In the Unmapped area, select the column name (Typical) in the Client section and the column name (Typical) that is newly added in R4.05 to the AD Suite section.
4. Click [Map].
   The pair is moved to the Mapped area.

Exporting mapping information

You can export the mapping information of the I/O information list and the safety I/O list to a Microsoft Excel xlsx format file in the Column Mapping dialog box. Follow these steps to export the mapping information:

1. In the Column Mapping dialog box, click [Export].
   The Select a location and set a file name dialog box appears.
2. Specify the export location and file name, and click the [OK] button.

Importing mapping information

You can import the exported mapping information. Follow these steps to import the mapping information:

1. In the Column Mapping dialog box, click [Import].
   The File Selection dialog box appears.
2. Specify the Microsoft Excel xlsx file of the mapping information to be imported, and click [OK].

D1.4.3 Comparing and reflecting the I/O information before and after import

Follow these steps to compare the I/O information before and after import and reflect it in the safety I/O list:

1. Select the [Mode] settings of the Comparison and Settings screen in the Import wizard from the following options.
   - To compare the added, modified, and deleted I/O information, select [All Check (Add/Update/Delete)].
   - To compare the added and modified I/O information, select [Part Check (Add/Update)].
2. Click [Finish].
   The Safety I/O Editor switches to Deviation mode.

   The imported I/O information is displayed on the left pane of the Safety I/O Editor, while the current safety I/O list is displayed on the right pane. In this case, the differences in the I/O information are displayed in blue color.

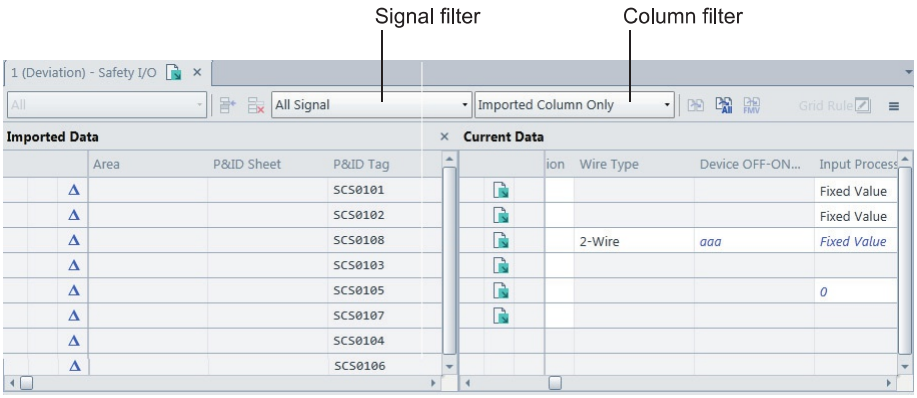

Figure D1.4.3-1 Safety I/O Editor for Deviation mode during import

TIP

- The I/O information before and after the import are compared using the P&ID tag as the key. If there is no relevant P&ID tag for the current safety I/O list, a new row is added to the safety I/O list.
- If a column value is not available in the imported file, the default value of that column is double-underlined to be displayed as the Imported Data. If the value of a column is not available in the imported file as well as in Current Data, the value is not imported.

3. You need to select the operation to reflect the imported I/O information list to the safety I/O list from the following.
   - To reflect only the selected I/O information, click the [Reflect Selected Area] button of the Safety I/O Editor tool bar in Deviation mode. The differences present in the selected range are reflected in the safety I/O list.
   - To reflect the entire I/O information, click the [Reflect All (regardless of selection)] button of the Safety I/O Editor tool bar in Deviation mode. All differences present are reflected in the safety I/O list.

TIP

If the safety I/O list is not checked out, it will be checked out.

Switching the safety I/O list display in Deviation mode

You can switch the Safety I/O Editor display in Deviation mode.

- Displaying for each edited content

The display of the safety I/O list in Deviation mode can be switched for each I/O point. You need to perform one of the following operations to switch the display.

- Displaying all I/O points
  Select [All Signal] in the signal folder of the Safety I/O Editor in Deviation mode.
- Displaying only the edited I/O points
  Select [Different Signal Only] in the signal folder of the Safety I/O Editor in Deviation mode.

- Displaying for each setting item
  The safety I/O list display can be switched in Deviation mode for each setting item. You need to perform one of the following operations to switch the display.
  - Displaying all setting items
    Select [All Column] in the column folder of the Safety I/O Editor tool bar in Deviation mode.
  - Displaying only the imported setting items
    Select [Imported Column Only] in the column folder of the Safety I/O Editor tool bar in Deviation mode.

D1.4.4 Editing a safety I/O list

You can use the following methods to edit a safety I/O list:

- Edit a new safety I/O list directly without importing an I/O information list
  With this method, you add a row of settings for each I/O point one by one.
- Import an I/O information list
  With this method, you import an I/O information list file and edit as required.

Creating a safety I/O list without importing an I/O information list

The user can directly edit the safety I/O list by using the Safety I/O Editor.

1. Open the System Structure Navigator.
2. Create a new safety I/O list.
3. Edit the safety I/O list.
   The data can be edited in two ways: you can edit each row manually, or edit the data in batch by using grid rules.

Editing a safety I/O list

Follow these steps to edit a safety I/O list:

You can add I/O points to the safety I/O list if you start the Safety I/O Editor for a P&ID group or a target module.

1. Double-click the cell of the safety I/O list.
   A dialog box appears, asking you to confirm the check-out.
2. Click [Yes].
   The I/O points are checked out, and check-out icons appear in the safety I/O list.
3. Edit the cells of the safety I/O list.

TIP

- When assigning the input points to the I/O module, define RS Project, SCS, Node Type, Node, IOM Category, IOM Type, Unit, Slot, Terminal, and Duplex. When these values are defined, the I/O points are copied to the I/O_definition file under the SCS folder. In this case, if the node, I/O module folder, and I/O_definition file do not exist, they are created automatically.
- If you set I/O points for which the I/O module assignment information is not defined, all I/O points for which the P&ID group is the same, and for which the I/O module assignment information is not defined are checked out. When I/O information is entered in the I/O points for which the I/O module assignment information is defined, all I/O points which are assigned to the same I/O module are checked out.

Adding I/O points to the safety I/O list

Follow these steps to add the I/O points to the safety I/O list:

1. Select I/O points from the safety I/O list. You can select I/O points in the following ways:
   - Select one or more rows
   - Select only one cell
2. Click the [Add Row] button on the tool bar.
   When one or more rows have been selected, the selected number of rows are added above the selected rows.

   When only one cell has been selected, one row is added below the last row. The added I/O points are checked out.

TIP

The I/O points can be added to the safety I/O list when the Safety I/O Editor is started up for each P&ID group or target module.

Deleting I/O points to the safety I/O list

Follow these steps to delete the I/O points to the safety I/O list:

1. Select the I/O points to be deleted in the safety I/O list.
2. Click the [Delete Row] button on the tool bar.
   The selected I/O points are deleted.

D1.4.5 Exporting the I/O information in the safety I/O list

The I/O information of the safety I/O list can be exported to a Microsoft Excel xlsx format file. Follow these steps to export the I/O information in the safety I/O list:

1. Select the [Sub menu] button from the Safety I/O Editor, and select [Export].
   The Export dialog box appears.

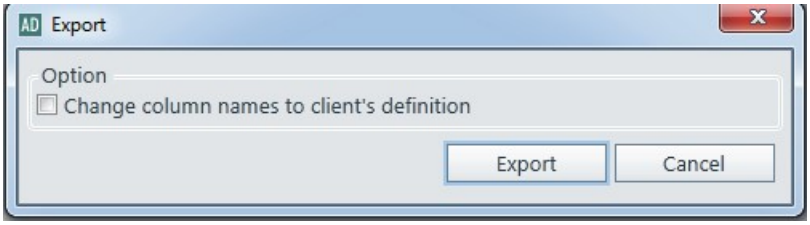

Figure D1.4.5-1 Export dialog box

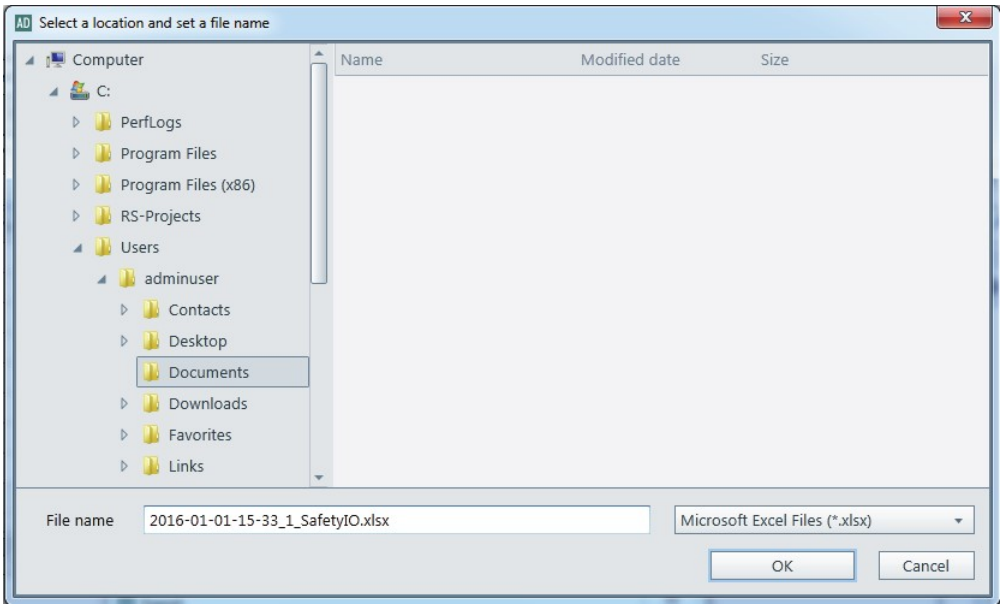
TIP

When the [Change column names to client's definition] check box is selected, and [Export] is clicked, the setting item name of the safety I/O list is changed based on the mapping information that is set while importing the I/O information list.

2. Click [Export].
   The Select a location and set a file name dialog box appears.



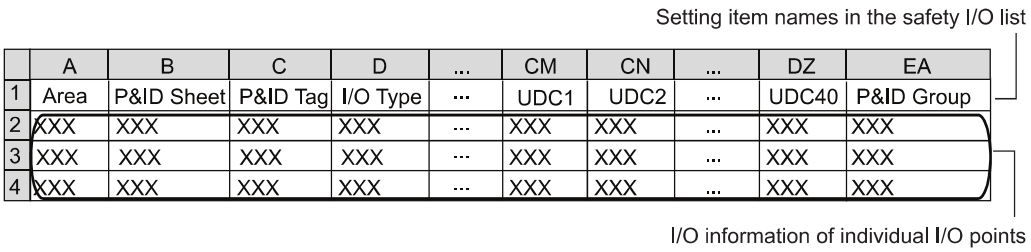


Figure D1.4.5-2 Select a location and set a file name dialog box

3. Specify the export location and file name, and click [OK].

Export file format

The exported file is created in the following format.

- File format
  Microsoft Excel .xlsx file
- Sheet name
  It will be the P&ID group name.
- Sheet description
  It is created in the following format.

	A	B	C	D	...	CM	CN	...	DZ	EA
1	Area	P&ID Sheet	P&ID Tag	I/O Type	···	UDC1	UDC2	···	UDC40	P&ID Group
2	XXX	XXX	XXX	XXX	···	XXX	XXX	...	XXX	XXX
3	XXX	XXX	XXX	XXX	···	XXX	XXX	...	XXX	XXX
4	XXX	XXX	XXX	XXX	···	XXX	XXX	...	XXX	XXX

Figure D1.4.5-3 Sheet description

TIP

If you assign an alias to a user-defined column, the Setting item name in the safety I/O list that corresponds to the user-defined column becomes an alias.

D1.4.6 Purpose of user definition and changing user-defined name

In addition to the default setting items, 40 setting items that users can define freely are provided in the safety I/O list. I/O information that is included in the user-defined setting items is reference information. This I/O information is not reflected to the SCS project. However, when engineering by using iDefine, the user-defined I/O information is included in the ProSafe-RS I/O file. As such, we recommend that you configure the ID and other information that you want to refer to when creating an application logic by using iDefine here. If you assign an alias to a user-defined column, the user-defined column header of the ProSafe-RS I/O file that is exported to iDefine becomes the defined alias.

You can use the user-defined setting items as reference information when using the grid rules.

Any name can be specified for the user-defined setting items. Follow these steps to specify any name for the user-defined setting items:

1. Select User Define Column Setting from the sub menu of the safety I/O list.
   The User Define Column Setting dialog box appears.

   The initial value of the setting item name is displayed in User Definition Column.

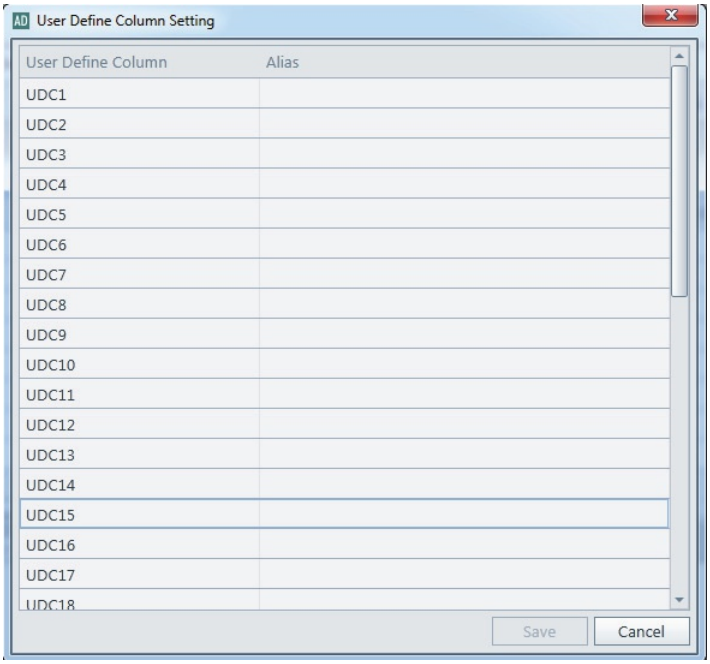

Figure D1.4.6-1 User Define Column Setting dialog box

2. Enter the name that needs to be changed in [Alias], and click [Save].
   The new name is displayed in the user-defined setting item of the safety I/O list.

D1.5 Using the safety I/O parameter profile

The safety I/O parameter profile is a named set of I/O channel parameter values. The I/O channel parameters can be configured all at once by applying the predefined safety I/O parameter profile to the I/O of the safety I/O list. Consistency can be ensured in I/O channel parameter settings for which the same profile has been applied by applying the safety I/O parameter profile to the I/O of multiple safety I/O lists. If you have changed the parameter values of a safety I/O parameter profile, you can reflect the modifications to the I/O of all safety I/O lists for which the profile has been applied.

Steps for using the safety I/O parameter profile

This section describes the following steps for using the safety I/O parameter profile:

- Starting Safety I/O Parameter Profile Editor
- Checking out the safety I/O parameter profile
- Defining the safety I/O parameter profile
- Deleting the safety I/O parameter profile
- Saving and checking in the safety I/O parameter profile
- Assigning the safety I/O parameter profile to the I/O parameter of the safety I/O list
- Reflecting the updated safety I/O parameter profile to the I/O of the safety I/O list
- Exporting the safety I/O parameter profile
- Importing the safety I/O parameter profile
- Behaviors when importing the safety I/O list with the safety I/O parameter profile assigned

D1.5.1 Starting Safety I/O Parameter Profile Editor

Perform this step to start Safety I/O Parameter Profile Editor:

- In System Structure Navigator, under I/O-Profiles, double-click [Safety I/O Parameter Profile].
  The Safety I/O Parameter Profile Editor appears in the document window area of the AD Organizer.

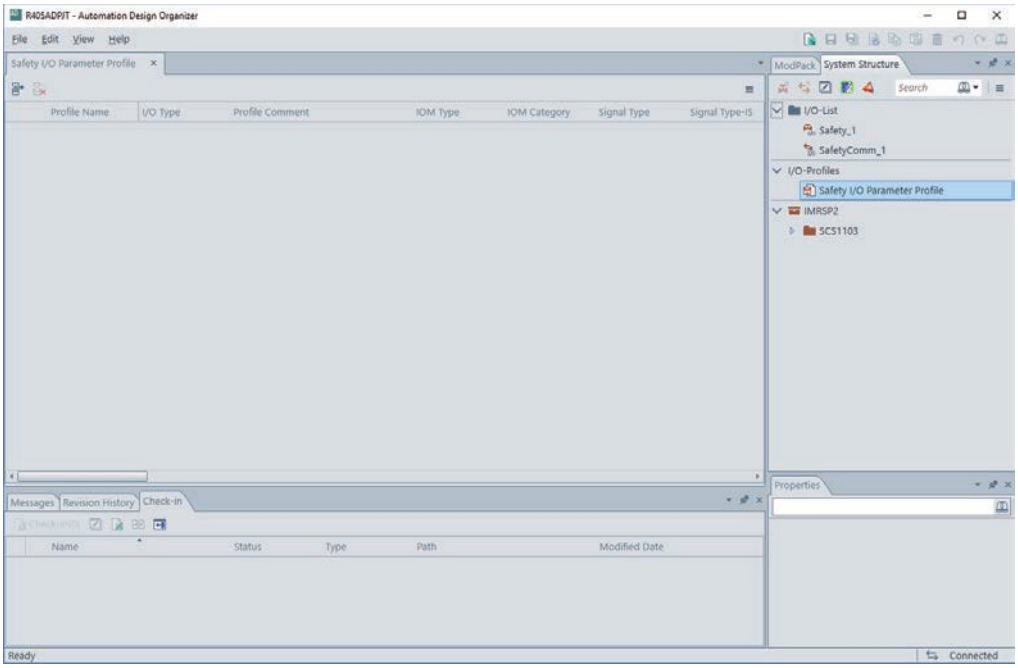

Figure D1.5.1-1 Safety I/O Parameter Profile Editor

TIP

If the safety I/O parameter profile has been defined, rows appear in the I/O parameter list area.

D1.5.2 Checking out the safety I/O parameter profile

You must check out a safety I/O parameter profile before defining it.

Perform this step to check out a safety I/O parameter profile:

- In System Structure Navigator, with the safety I/O parameter profile selected, click [Check-out] on the tool bar of AD Organizer.

SEE ALSO For more information about check-out operation, refer to:

"■ Checking out manually" in B4.2.1, "Check-out" in Engineer's Reference Manual (IM 32P04B10-01EN)

D1.5.3 Defining the safety I/O parameter profile

Follow these steps to define the safety I/O parameter profile:

1. In Safety I/O Parameter Profile Editor, click [Add row(s)].
   A row of profiles is added to the I/O parameter list area.
2. Type the name of the safety I/O parameter profile and press [Enter].
   The name of the safety I/O parameter profile is set.
3. Click the necessary column cell and define the profile.

TIP

The maximum number of safety I/O parameter profiles that you can define is 1000.

Definition items of the safety I/O parameter profile

The following table describes a list of the definition items of the safety I/O parameter profile.

Table D1.5.3-1 List of definition items of the safety I/O parameter profile

Column name	Description
Profile Name (*1)	Name of the I/O parameter profile.
I/O Type (*1)	I/O type
Profile Comment	Comment for the profile. Displayed as a tooltip in the I/O parameter profile column of Safety I/O Editor.
IOM Type (*1)	I/O Module name
IOM Category (*1)	I/O Module type
Signal Type	Signal type
Signal Type-IS	Signal type of the base plate for barrier for N-IO
Signal Conversion	Signal conversion
Signal LO	Low limit of the field I/O signal
Signal HI	High limit of the field I/O signal
Signal Unit	Engineering unit of the field I/O signal
Wire Type	Wire type of N-IO
Device OFF-ON Variable Name	Variable names for instructing a reset of fire and gas equipment
Reset Group ID	Reset Group ID
Input Processing at Fault	Input processing at fault
Input Value at Fault %	Input value at fault
Input Processing at Transmitter Fault	Specify input at transmitter fault
Detect IOP (High)	Detect IOP (High)
Detect IOP (Low)	Detect IOP (Low)
IOP High Limit	Threshold of IOP (High) %
IOP Low Limit	Threshold of IOP (Low) %
Detect Transmitter Fault (High)	Detect Transmitter Fault (High)
Detect Transmitter Fault (Low)	Detect Transmitter Fault (Low)
Threshold of Transmitter Fault (High) %	Threshold of Transmitter Fault (High)
Threshold of Transmitter Fault (Low) %	Threshold of Transmitter Fault (Low)
Field Power Diagnosis	Field Power Diagnosis
Reference Junction Compensation	Reference junction compensation

Continues on the next page

Table D1.5.3-1 List of definition items of the safety I/O parameter profile (Table continued)

Column name	Description
Burnout	Specify burnout
Time to Chattering Recovery Notice (s)	Time to chattering recovery notice
I/O Shutoff Switch	Specify I/O shutoff switch of N-IO
Output Shutoff Switch	Specify output shutoff switch of FIO and DO shutoff switch of N-IO
Output Processing at Fault	Specify output processing at fault
Output Value at Fault %	Output value at fault
Tight-shut/Full-open	Specify Tight-shut/Full-open
Tight-shut Value %	Tight-shut value
Full-open Value %	Full-open value
Detect Short Circuit	Detect short circuit
Detect Disconnection	Detect disconnection
Detect LFD	Detect LFD
Pulse Test	Pulse test
Pulse Test (OFF)	Pulse test (OFF)
Pulse Test (ON)	Pulse test (ON)
Low Voltage Pulse Test (ON)	Low voltage pulse test (ON)
SOER	SOER setting
Trip Signal (Setting for SOER)	Specify trip signal
Command	Command

*1: Mandatory definition items

When you define items other than Profile Name, I/O Type, Profile Comment, IOM Type, and IOM Category in the safety I/O parameter profile, the items will be reflected to the I/O of the safety I/O list.

D1.5.4 Deleting the safety I/O parameter profile

Follow these steps to delete the safety I/O parameter profile:

1. In the I/O parameter list area of Safety I/O Parameter Profile Editor, select the safety I/O parameter profile to delete.
2. On the tool bar of Safety I/O Parameter Profile Editor, click [Delete row(s)].
   The selected safety I/O parameter profile is deleted.

IMPORTANT

- Do not delete safety I/O parameter profiles that are in use.
- An error occurs if you try to delete a safety I/O parameter profile that is in use and perform check-in.

SEE ALSO For more information about unassignment of safety I/O parameter profile, refer to:

D1.5.6, “Assigning the safety I/O parameter profile to the I/O of the safety I/O list” on page D1-33

D1.5.5 Saving and checking in the safety I/O parameter profile

Save and check in the safety I/O parameter profile. This operation saves the safety I/O parameter profile in the AD project.

Follow these steps to save and check in the safety I/O parameter profile:

1. While the focus is on Safety I/O Parameter Profile Editor, click [Save] on the tool bar of AD Organizer.
2. In the Check-in window, perform a check-in of the defined safety I/O parameter profile. The check-out icon of the safety I/O parameter profile disappears.

TIP

The safety I/O parameter profile also appears in the following editors and window:

- Grid Rule Editor
- ModPack Editor
- Revision History Window

SEE ALSO

For more information about operations for a check-in, refer to:

"■ Checking in manually" in B4.2.4, "Check-in" in Engineer's Reference Manual (IM 32P04B10-01EN)

D1.5.6 Assigning the safety I/O parameter profile to the I/O of the safety I/O list

The safety I/O parameter profile that has been defined by using Safety I/O Editor is assigned to the I/O of the safety I/O list.

Follow these steps to assign the safety I/O parameter profile to the I/O of the safety I/O list:

1. Start the Safety I/O Editor in edit mode.
2. In Safety I/O Editor, select the cell of the I/O Parameter Profile column for the row for which you want to assign the safety I/O parameter profile.
   A drop-down list appears.
3. Select the safety I/O parameter profile to assign.
   The I/Os of the selected safety I/O parameter profile are assigned to the safety I/O list.

TIP

- The safety I/O parameter profile in which the I/O Type, IOM Type, and IOM Category match is assigned to the I/O of the safety I/O list.
- The I/Os with a safety I/O parameter profile assigned become read-only in Safety I/O Editor.
- To unassign the safety I/O parameter profile, select the cell of the corresponding I/O Parameter Profile column in Safety I/O Editor and delete the profile name.

D1.5.7 Reflecting the updated safety I/O parameter profile to the I/O of the safety I/O list

If you modify a safety I/O parameter profile in Safety I/O Parameter Profile Editor after assigning it to the I/O of the safety I/O list, reflect the changes in the safety I/O list.

The following methods can be used to reflect the updated safety I/O parameter profile to the I/O of the safety I/O list:

- Reflecting it in the safety I/O list by using Safety I/O Editor
- Reflecting it in the safety I/O list by using the I/O Parameter Update dialog box

■ Reflecting it in the safety I/O list by using Safety I/O Editor

Follow these steps to reflect the updated the safety I/O parameter profile in the safety I/O list by using Safety I/O Editor:

1. Start the Safety I/O Editor in edit mode.
2. In Safety I/O Editor, right-click the cell of the row in which the safety I/O parameter profile is to be reflected and select [Update I/O Parameter].
   The updated safety I/O parameter profile is reflected to the I/O of the safety I/O list.

TIP

- I/O parameter profiles that are not updated appear in yellow.
- In Safety I/O Editor, you can select the cells of the rows in which multiple safety I/O parameter profiles are to be reflected and reflect the changes.

3. While the focus is on Safety I/O Editor, click [Save] on the tool bar of AD Organizer.
4. By using the Check-in window, check in the reflected safety I/O list.

SEE ALSO

For more information about starting Safety I/O Editor in edit mode, refer to:

"■ Starting the Safety I/O Editor for editing" on page D1-6

For more information about operations for a check-in, refer to:

"■ Checking in manually" in B4.2.4, "Check-in" in Engineer's Reference Manual (IM 32P04B10-01EN)

■ Reflecting it in the safety I/O list by using the I/O Parameter Update dialog box

Follow these steps to reflect the updated the safety I/O parameter profile in the safety I/O list by using the I/O Parameter Update dialog box:

1. In System Structure Navigator, under I/O-Profiles, right-click [Safety I/O Parameter Profile] and select [Update I/O Parameter].
   The I/O Parameter Update dialog box appears.

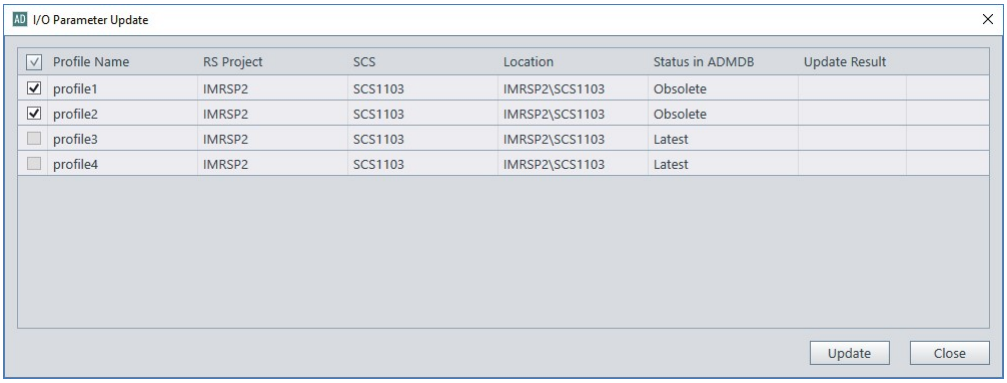

Figure D1.5.7-1 I/O Parameter Update dialog box

TIP

When the I/O Parameter Update dialog box appears, all safety I/O parameter profiles with items that have not been updated are selected. Safety I/O parameter profiles that have been updated cannot be selected.

2. Select the safety I/O parameter profile to update and click [Update].
   The updated safety I/O parameter profile is reflected to the I/O of the safety I/O list.
3. By using the Check-in window, check in the reflected safety I/O list.

SEE ALSO

For more information about operations for a check-in, refer to:

"■ Checking in manually" in B4.2.4, "Check-in" in Engineer's Reference Manual (IM 32P04B10-01EN)

D1.5.8 Exporting the safety I/O parameter profile

You can export the safety I/O parameter profile. Follow these steps to export the safety I/O parameter profile:

1. In the I/O parameter list area of Safety I/O Parameter Profile Editor, select one or multiple safety I/O parameter profiles to export.
2. In Safety I/O Parameter Profile Editor, click [Sub menu] and select [Export].
   The Folder selection dialog box appears.
3. Select the folder to which you want to export the safety I/O parameter profile and click [OK].

TIP

One file is exported and saved in xlsx format.

D1.5.9 Importing the safety I/O parameter profile

You can import the safety I/O parameter profile. Follow these steps to import the safety I/O parameter profile.

TIP You need to perform the check-out of a safety I/O parameter profile before importing it.

1. In Safety I/O Parameter Profile Editor, click [Sub menu] and select [Import].
   The File selection dialog box appears.
2. Select the safety I/O parameter profile file to import and click [OK].
   The safety I/O parameter profile that was imported in the I/O parameter list area appears.

TIP If you are importing a safety I/O parameter profile for the first time, assign the profile to the safety I/O list after the import. If you are importing an updated safety I/O parameter profile, reflect the changes to the I/O of the safety I/O list after the import.

SEE ALSO For more information about assigning the safety I/O parameter profile to the I/O of the safety I/O list, refer to:

D1.5.6, “Assigning the safety I/O parameter profile to the I/O of the safety I/O list” on page D1-33

For more information about reflecting the updated safety I/O parameter profile to the I/O of the safety I/O list, refer to:

D1.5.7, “Reflecting the updated safety I/O parameter profile to the I/O of the safety I/O list” on page D1-34

If a safety I/O parameter profile with the same name as the safety I/O parameter profile to be imported already exists in the AD Project

If a safety I/O parameter profile with the same name (not case-sensitive) as the safety I/O parameter profile to be imported already exists in the AD Project, the following Resolve Import Conflict dialog box appears when importing the safety I/O parameter profile.

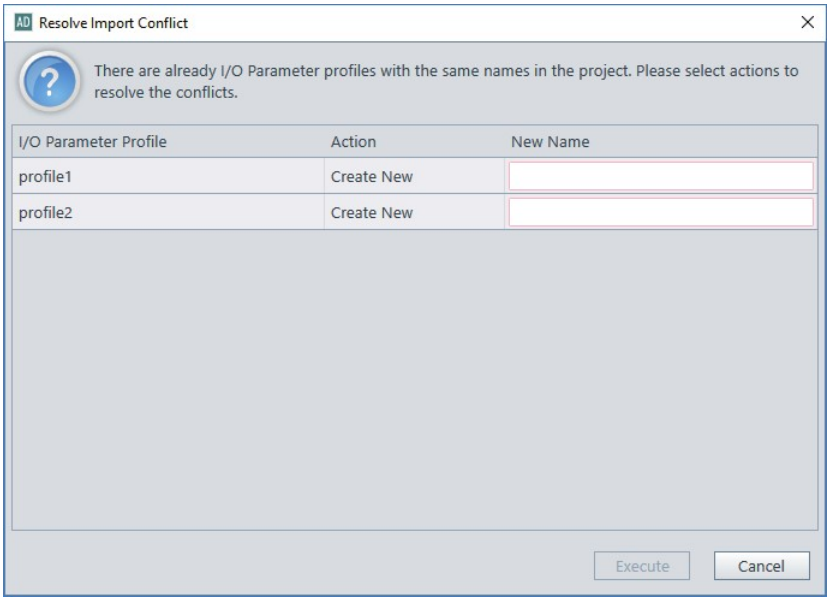

Figure D1.5.9-1 Resolve Import Conflict dialog box

If the Resolve Import Conflict dialog box appears, follow any of these steps:

- When importing by overwriting the existing safety I/O parameter profile
  In Action, select [Update] and click [Execute].

- When importing as a different safety I/O parameter profile
  In Action, select [Create New] and click [Execute] after entering a name that does not exist in New Name.
- When canceling the import
  In Action, select [Cancel] and click [Execute].

D1.5.10 Behaviors when importing the safety I/O list with the safety I/O parameter profile assigned

The safety I/O list is imported to Safety I/O Editor based on the P&ID Tag. When importing the safety I/O list with the safety I/O parameter profile assigned, the status of the I/O Parameter Profile column and I/O channel parameters in Safety I/O Editor become as follows:

If the safety I/O parameter profile name is changed by the import and the safety I/O parameter profile with the same name as the one after the change exists in the AD project, the I/O channel parameters are updated based on the corresponding safety I/O parameter profile that exists in the AD project.

However, if there are no changes in the safety I/O parameter profile name used before and after the import, the I/O channel parameters remain their status the same as before the import.

In addition, the I/O Parameter Profile column of the safety I/O list is shown in pink to indicate erroneous data after the import in the following cases:

- When the safety I/O parameter profile with the same profile name does not exists in the AD project
- When the safety I/O parameter profile with the same profile name exists in the AD project, but the I/O Type, IOM Type, and IOM Category do not match

In this case, take the necessary measures such as profile registration, profile name change, and profile deletion.

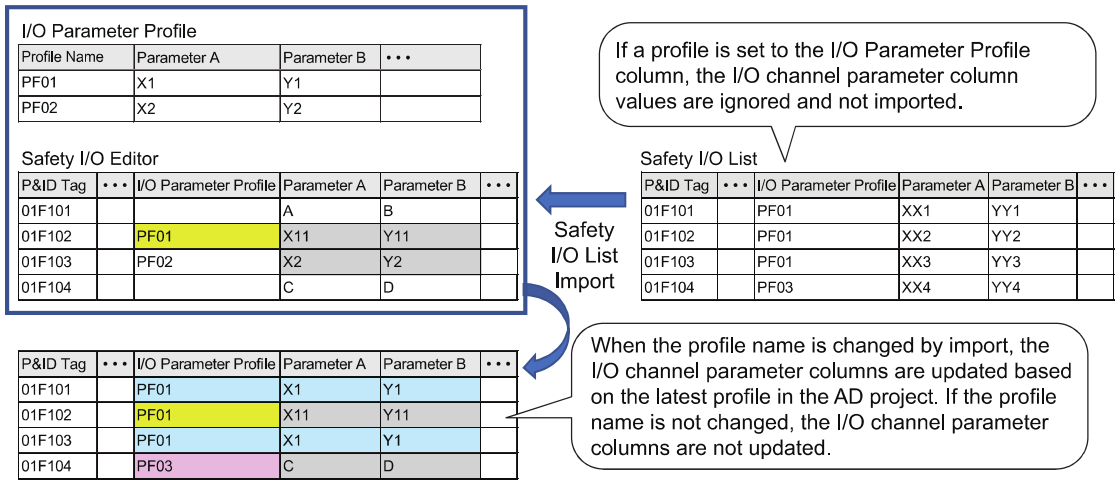

Figure D1.5.10-1 Status of the I/O parameter profile column in Safety I/O Editor after importing the safety I/O list

D1.5.11 Precautions for importing and restoring SCS projects including safety I/O parameters

This section describes precautions for importing and restoring SCS projects including safety I/O parameters.

Importing SCS

The behaviors when importing the SCS project including the safety I/O list with the safety I/O parameter profile assigned is as follows:

- If the safety I/O parameter profile with the same profile name does not exist in the AD project, the import ends up in a failure.
  If importing SCS fails, register the safety I/O parameter profile in the AD project and then import SCS again.
- If the safety I/O parameter profile with the same profile name exists in the AD project, and the imported I/O parameter value is the same as the I/O parameter value of the safety I/O parameter profile of the AD project, the import ends up in a success.
- If the safety I/O parameter profile with the same profile name exists in the AD project, and the imported I/O parameter value is different from the I/O parameter value of the safety I/O parameter profile of the AD project, the import ends up in a success. However, since the I/O parameter values are different from the values stored in the AD project, the values of the import source SCS are applied. The I/O Parameter Profile column of the safety I/O list is shown in yellow to indicate that there is a difference.
  If there is a difference, update the I/O parameter value as necessary.

Restoring SCS projects by Version Control Tool and Master Database Restoring function

The behaviors when restoring the SCS project including the safety I/O list to which the safety I/O parameter profile is assigned using the Version Control Tool and Master Database Restoring function is as follows:

- If the safety I/O parameter profile with the same profile name does not exist in the AD project, the restoring ends up in a failure.
  If the restoring fails, register the safety I/O parameter profile in the AD project and then restore the SCS project again.
- If the safety I/O parameter profile with the same profile name exists in the AD project, and the restored I/O parameter value is the same as the I/O parameter value of the safety I/O parameter profile of the AD project, the restoring ends up in a success.
- If the safety I/O parameter profile with the same profile name exists in the AD project, and the restored I/O parameter value is different from the I/O parameter value of the safety I/O parameter profile of the AD project, the restoring ends up in a success. However, since the I/O parameter values are different from the values stored in the AD project, the values of the restoring source SCS are applied. The I/O Parameter Profile column of the safety I/O list is shown in yellow to indicate that there is a difference.
  If there is a difference, update the I/O parameter value as necessary.

D1.6 Saving the safety I/O list and performing check-in

You can save the safety I/O list and perform check-in. By performing this operation, the safety I/O list is stored in the AD project.

Saving the safety I/O list

Follow these steps to save the safety I/O list:

1. Select the Safety I/O Editor.
2. On the tool bar of AD Organizer, click the [Save] button.

TIP

- When the I/O module assignment information of the safety I/O list is edited, the safety I/O list (I/O_definition) in the I/O module of the assignment destination is automatically checked out, and the content of the definition is reflected.
- When the Safety I/O Editor is in Deviation mode, you cannot save the safety I/O list.

Performing check-in of the safety I/O list

In the Check-in window, check in the defined safety I/O list.

The check-out icon of the safety I/O list disappears.

D2. Engineering based on the safety communication I/O list

The I/O information of the safety communication I/O list can be defined, browsed, or edited by using Safety Communication I/O Editor. With the safety communication I/O list, you can manually enter I/O information or import and edit an I/O information list obtained from a plant designer. The items subject to definitions of the safety communication I/O list are the following communication categories and module types amongst the FIO.

Table D2-1 Items subject to definitions of the safety communication I/O list

Communication category	Module type
Serial	ALR111M, ALR121M (for subsystem communication)
Ethernet	ALE111M (for subsystem communication)
PROFINET	S2LP131 (for safety subsystem communication)

With the safety communication I/O list, you can configure Ethernet communication I/O, serial communication I/O, and fire and gas communication I/O for each I/O point.

The following shows the work flow of engineering for the safety communication I/O list.

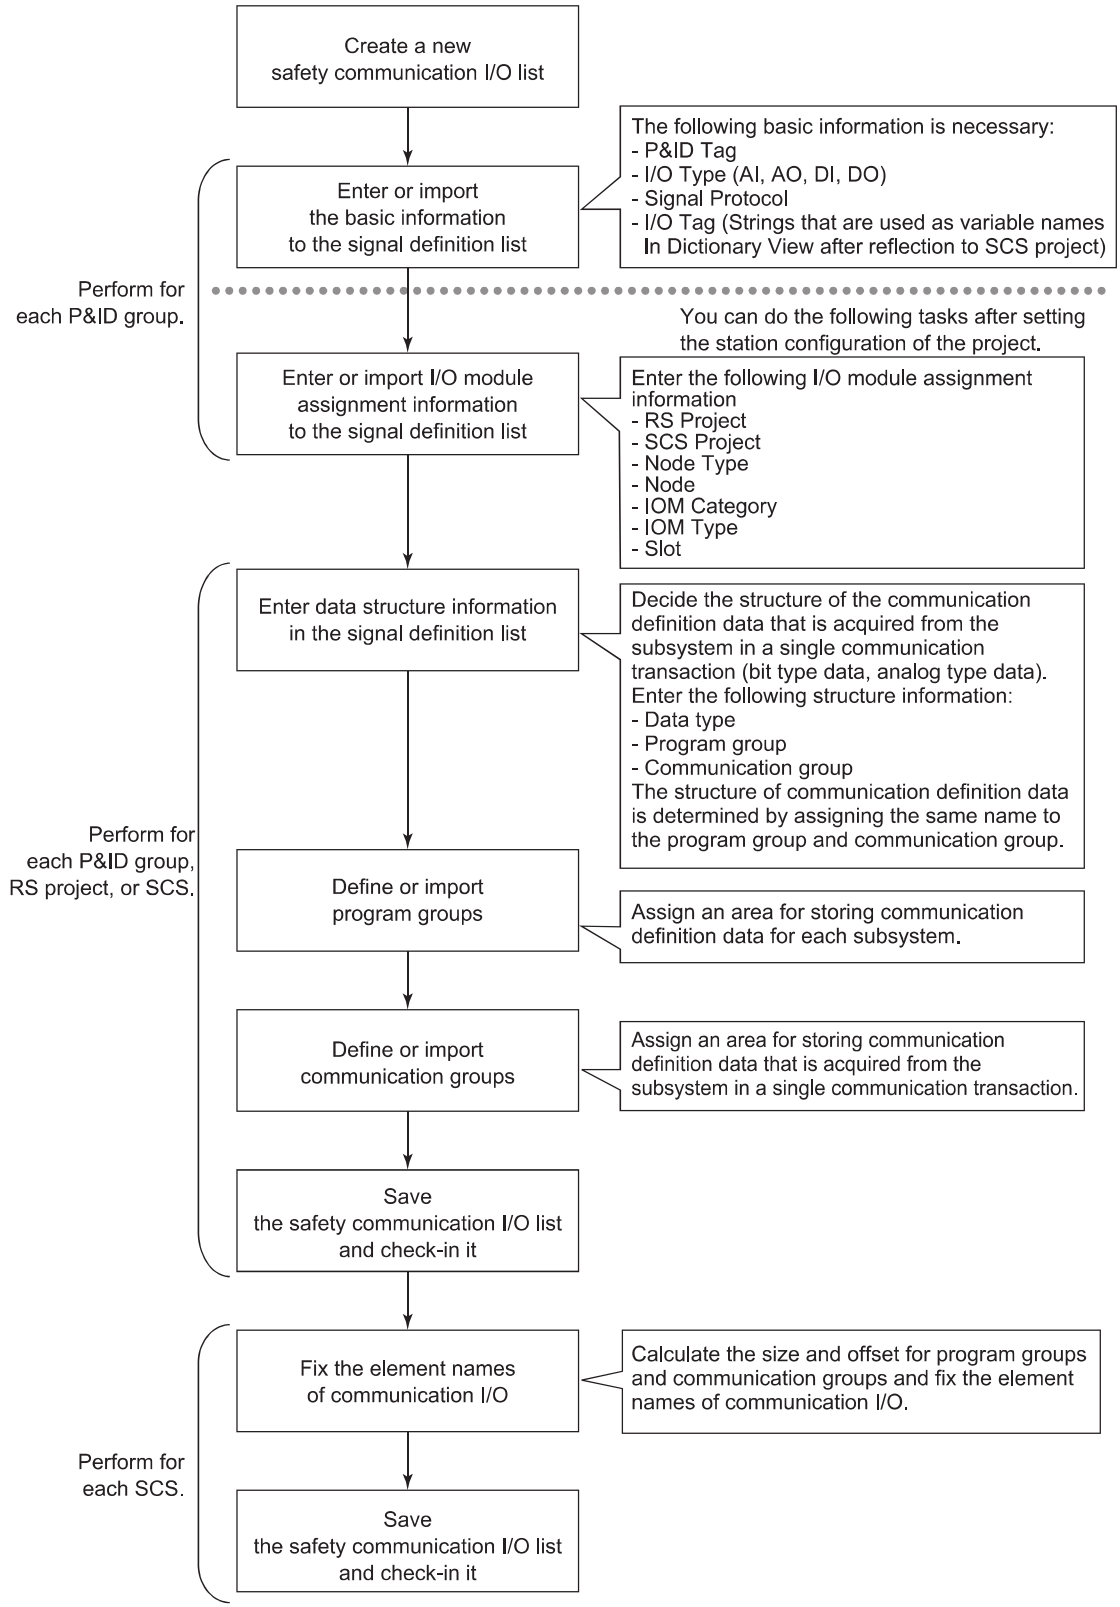

Figure D2-1 Work flow of engineering for the safety communication I/O list

SEE ALSO

For more information about operations for every P&ID group and SCS, refer to:

"■ Starting the Safety Communication I/O Editor for editing" on page D2-6

For more information about data structures, program groups, and communication groups, refer to:

D2.5.1, "Overview of definitions for communication with subsystems" on page D2-22

D2.1 Creating a new safety communication I/O list

Follow these steps to create a safety communication I/O list:

1. Select the I/O-List folder of System Structure Navigator.
2. From the context menu, select [New Safety Communication I/O].
   The newly created safety communication I/O list appears in the edit mode in System Structure Navigator.
3. Enter a unique safety communication I/O list name.
   A new safety communication I/O list is created. Once the list is newly created, it is automatically checked in to the server.

TIP

The safety communication I/O list name that is entered is referred to as the P&ID group.

SEE ALSO

For more information about how to change the name of a safety communication I/O list after creating the safety communication I/O list, refer to:

"■ Changing the name of the safety communication I/O list" on page D2-5

For more information about the maximum number of safety communication I/O lists, refer to:

A4., "Application capacity of AD Suite" in Engineer's Reference Manual (IM 32P04B10-01EN)

■ Folder location of the safety communication I/O list definition

After RS Project and SCS Project are set in the safety communication I/O list, a file containing the I/O information for an individual SCS is copied to the Comm_I/O folder under the corresponding SCS folder.

Thereafter, you can select the Comm_I/O folder to start Safety Communication I/O Editor from the context menu. Only the contents that are defined in the corresponding file are shown in the editor.

D2.2 Operating a safety communication I/O list

This section describes how to rename and delete a safety communication I/O list.

Changing the name of the safety communication I/O list

Follow these steps to change the name of the safety communication I/O list:

1. Right-click on the safety communication I/O list in System Structure Navigator and select [Rename].
   The P&ID group of the safety communication I/O list name appears in the edit status.
2. Enter a new P&ID group.
   The name of the safety communication I/O list changes.

Deleting the safety communication I/O list

You need to delete the safety communication I/O list after deleting all I/O information that is assigned to the I/O module. Follow these steps to delete the safety communication I/O list:

- Select the safety communication I/O list in System Structure Navigator and click [Delete] on the tool bar of AD Organizer.

TIP

- When the Safety Communication I/O Editor is running, the safety communication I/O list cannot be deleted.
- You can delete only one safety communication I/O list at a time.

SEE ALSO

For more information about input/output module assignment information, refer to:

D2.4, “Entering I/O information in the signal definition list” on page D2-17

D2.3 Starting Safety Communication I/O Editor

You can start the Safety Communication I/O Editor from the System Structure Navigator in AD Organizer. The modes of the Safety Communication I/O Editor are edit mode, revision history mode and read-only mode.

You can open two windows simultaneously with the following combination:

- Edit mode and read-only mode
- Revision history mode and read-only mode

You cannot open two windows with the combination of edit mode and revision history mode.

Starting the Safety Communication I/O Editor for editing

Depending on the operation purpose, method for starting Safety Communication I/O Editor varies.

IMPORTANT

To edit I/O information for each RS project or SCS, you can start Safety Communication I/O Editor after setting the station configuration and defining the I/O module assignment information in the signal definition list.

Perform one of the following operations using the System Structure Navigator to start the Safety Communication I/O Editor:

- When editing I/O information for each P&ID group
  Double-click the safety communication I/O list in the [I/O-List] folder.

  Safety Communication I/O Editor appears in the document window area of AD Organizer and the I/O points belonging to the P&ID group appear in the safety communication I/O list.
- When editing I/O information for each applicable RS project
  Right-click the RS project in System Structure Navigator and select [Open] > [Safety Communication I/O Editor].

  Safety Communication I/O Editor appears in the document window area of AD Organizer and the I/O points belonging to the applicable RS project appear in the safety communication I/O list.
- When editing I/O information for each applicable SCS
  In System Structure Navigator, double-click on [Comm_I/O] under the applicable SCS.

  Safety Communication I/O Editor appears in the document window area of AD Organizer and the I/O points belonging to the applicable SCS appear in the safety communication I/O list.

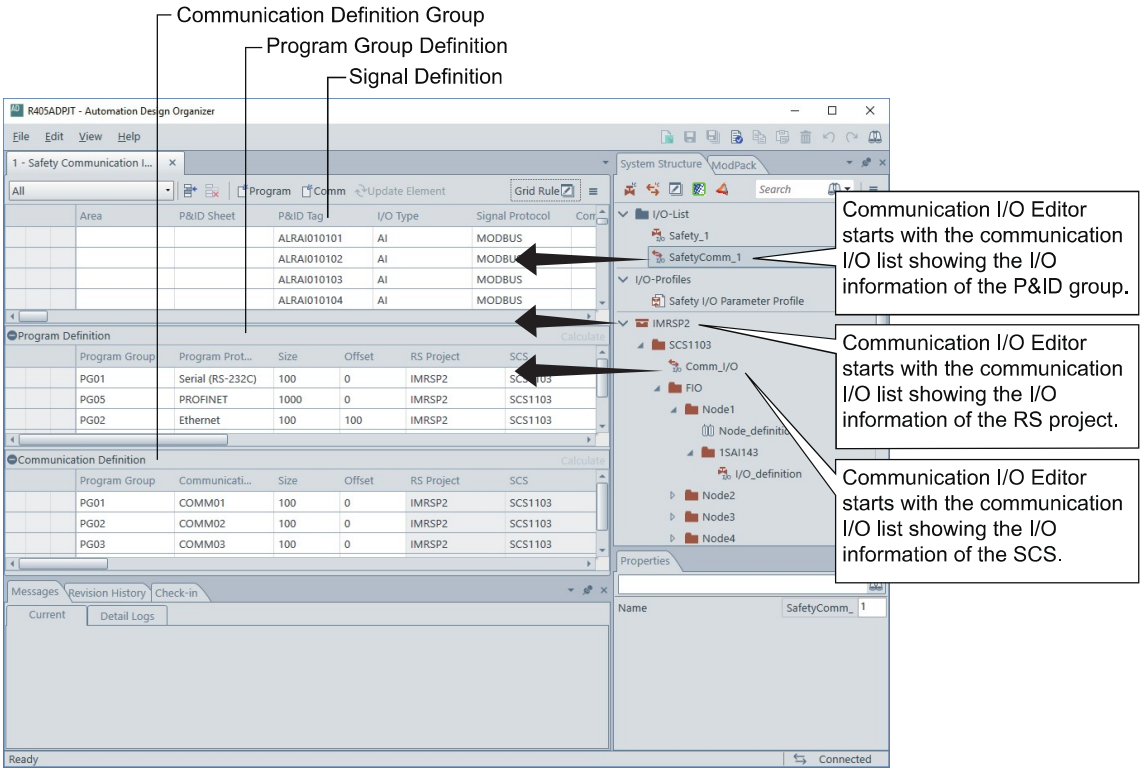

Figure D2.3-1 Safety Communication I/O Editor

TIP

- In the safety communication I/O list, Ethernet communication I/O and serial communication I/O for subsystem communication and fire and gas communication I/O for safety subsystem communication are each shown with a line for every I/O point.
- The program group definition list and communication group definition list are defined for each SCS regardless of how Safety Communication I/O Editor is started.
- When Safety Communication I/O Editor is started, information of the source from which you started the editor is shown in the window title.

The functions that you can use will vary depending on the project and definition items that were selected prior to starting Safety Communication I/O Editor. The following table shows the differences.

Table D2.3-1 Differences of functions depending on how the editor is started

Definition item or project selected upon startup	Export function (*1)	Import function (*1)	Size/Element automatic calculation	Editing of the Wiring column
P&ID group (I/O-list)	Yes	Yes	No	Read-only
RS project	Yes	No	No	Read-only
SCS project	Yes	No	Yes	Write-only

*1: Indicates whether or not the function will operate.
Yes: The function can be operated
No: The function cannot be operated

Starting the Safety Communication I/O Editor for read-only

Depending on the operation purpose, method for starting Safety Communication I/O Editor varies.

- Perform one of the following operations using the System Structure Navigator to start the Safety Communication I/O Editor in read-only mode:

- When reading definitions for each P&ID group
  Right-click the safety communication I/O list in the [I/O-List] folder and select [Open (Read-Only)].
- When reading definitions for each applicable RS project
  Right-click the RS project and select [Open (Read-Only)] > [Safety Communication I/O Editor].
- When reading definitions for each applicable SCS
  Right-click the [Comm I/O] under the applicable SCS and select [Open (Read-Only)].

The Safety Communication I/O Editor appears in the document window area in read-only mode.

TIP

If content is being edited in the edit mode editor, the contents being edited are also reflected in the read-only mode editor. However, the update is manual.

Switching the display of the safety communication I/O list

You can switch the display of the safety communication I/O list for each I/O type. Perform the following operation to switch the display:

- From the drop-down list on the upper-left pane of the safety communication I/O list, select the items you wish to display.

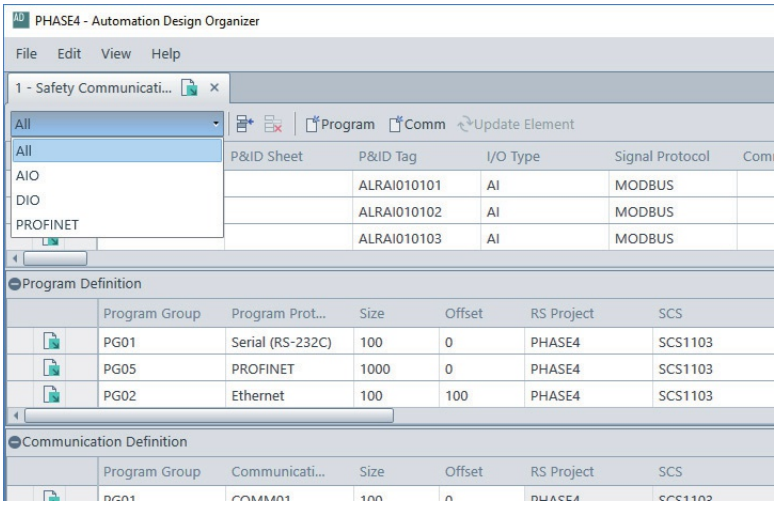

Figure D2.3-2 Drop-down list for switching the display

Only the selected items are shown.

Setting items of Safety Communication I/O Editor

The following lists are defined with Safety Communication I/O Editor:

- Signal definition list
- Program group definition list
- Communication group definition list

The following figure shows where the lists are defined.

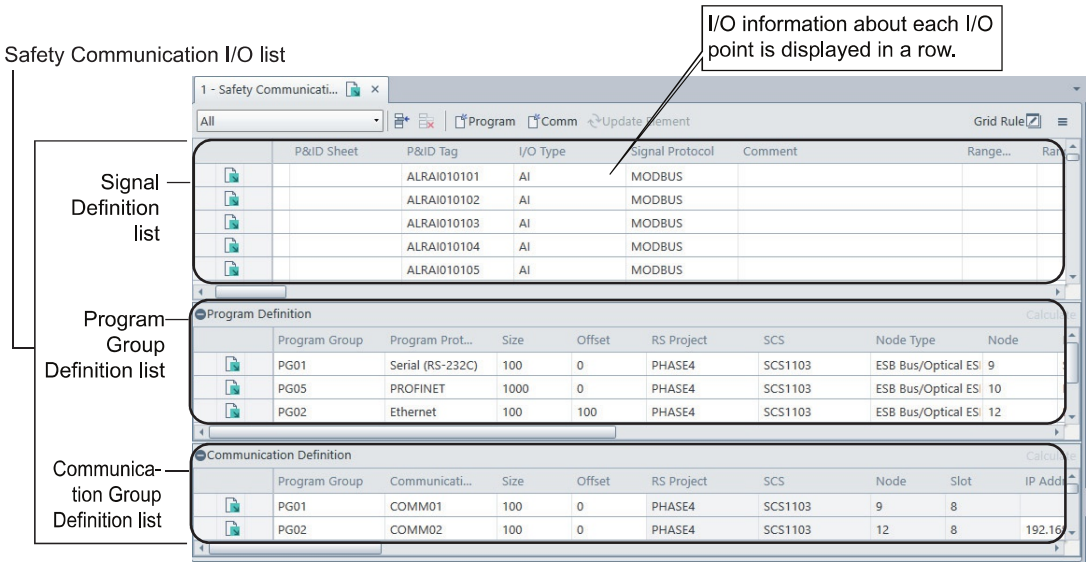

Figure D2.3-3 Window configuration of Safety Communication I/O Editor

The following table shows each of the setting items.

Setting items for the signal definition list

Table D2.3-2 List of setting items of the "signal definition list"

Category	Column name	Description	Mandatory setting or not (*1)	SCS Manager item where the setting is reflected through RS Generation
For I/O list management	Area	Area name	-	-
	P&ID Sheet	P&ID sheet name	-	-

Continues on the next page

Table D2.3-2 List of setting items of the "signal definition list" (Table continued)

Category	Column name	Description	Mandatory setting or not (*1)	SCS Manager item where the setting is reflected through RS Generation
I/O list common	P&ID Tag	P&ID tag name Key information required to identify each I/O. The P&ID tag must be unique within the P&ID group.	1	-
	I/O Type	I/O type. Select from the following: AI, AO, DI, DO	1	-
	Signal Protocol	The signal type. Select from the following: MODBUS MODBUS (SLS) PROFINET PROFIsafe	1	-
	Comment	The variable comment of the IO variable that is defined in Dictionary View.	-	Dictionary View: Comment Communication I/O Builder (Comm. I/O Wiring, PROFINET Comm. I/O Wiring)
	Range LO	Low limit	-	-
	Range HI	High limit	-	-
	Eng Unit	Engineering unit	-	-
	I/O Tag	I/O tag name Normally, set the same name as the P&ID tag, or an abbreviated form thereof. The I/O tag must be unique within the SCS. A character string that will become the variable name in Dictionary View after reflection onto the SCS project. Otherwise, a variable name that will be wired with Communication I/O Builder.	1	Dictionary View: Name Communication I/O Builder (Comm.I/O Wiring, PROFINET Comm.I/O Wiring)
	Variable Group	Variable Group	-	Dictionary View

Table D2.3-2 List of setting items of the "signal definition list" (Table continued)

Category	Column name	Description	Mandatory setting or not (*1)	SCS Manager item where the setting is reflected through RS Generation
IOM assignment information	RS Project	The SCS and IOM assignment information to which this signal is being assigned. By defining the Program Group column, the corresponding program group definitions are reflected and then later become read-only.	-	The content defined here is taken into IOM Definition Editor and then reflected onto I/O Wiring View when implementing RS Generation.
	SCS			
	Node Type			
	Node			
	IOM Category			
	IOM Type			
	Slot			
I/O description	Input Processing at Fault	Input processing at fault	-	Communication I/O Builder: Input Processing at Fault
	Input Value at Fault	Input value at fault		Communication I/O Builder: Input Value at Fault

*1: Whether column settings are required or not are indicated in the following categories:
Meaning of the Mandatory setting or not column
- 1: Configuration is always required
- 2: Configuration is required after assigning the I/O to SCS and IOM
- 3: Configuration is preferred after assigning the I/O to SCS and IOM
- -: Configuration is not required

Other settings items such as Connection Device Info, For I/O list management, For iDefine reference, and User Define Column also appear.

SEE ALSO

For more information about columns common to Safety I/O Definition Editor that are included in the signal definition list, refer to:

"■ Setting items of the Safety I/O Editor" on page D1-7

Setting items for the program group definition list

Table D2.3-3 List of setting items of the "program group definition list"

Category	Column name	Description	Mandatory setting or not (*1)	SCS Manager item where the setting is reflected through RS Generation
Program definition	Program Group	Defines the program group name	3	-
	Program Protocol	This is read-only. The value is selected from the following: • Serial (RS-232C) • Serial (RS-422) • Serial (RS-485) • Serial (RS-422/ RS-485) • Ethernet • PROFINET		-
	Size	The size of this program definition This becomes the area of %XW.		Communication I/O Builder: Buffer size (Program)
	Offset	Specifies the beginning position of this program definition as the offset from the beginning of the SCS communication I/O area. This becomes the first number of %XW.		Communication I/O Builder: Buffer
	RS Project	The name of the RS project to which this program definition will be assigned		-
	SCS	The SCS number to which this program definition will be assigned		-
	Node Type	The node type to which this program definition will be assigned (only "ESB Bus/Optical ESB Bus" can be selected).		-
	Node	The node number to which this program definition will be assigned		I/O Wiring View, I/O Parameter Builder
	IOM Category	The IOM category to which this program definition will be assigned. PROFINET for fire and gas devices		-
	IOM Type	The IOM type to which this program definition will be assigned		I/O Wiring View, I/O Parameter Builder
	Slot	The slot number to which this program definition will be assigned		I/O Wiring View, I/O Parameter Builder

	F_Par_CRC			
Safety communication I/O list management	P&ID Group	This is read-only. The value for the same column name of the program group definition.	-	-

*1: Whether column settings are required or not are indicated in the following categories: Meaning of the Mandatory setting or not column
- 1: Configuration is always required
- 2: Configuration is required after assigning the I/O to SCS and IOM
- 3: Configuration is preferred after assigning the I/O to SCS and IOM
- -: Configuration is not required

*2: When defining SLSEVENT, set only the program definition and communication definition without setting the signal definition. A signal cannot be associated with a communication group for the SLSEVENT definition. An error will occur when trying to save if a signal is defined.

*3: PROFINET Configurator can be started from Safety Communication I/O Editor.

SEE ALSO For more information about PROFINET Configurator, refer to:

E1.5.2, “Applying settings by using PROFINET Configurator” in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

D2.4 Entering I/O information in the signal definition list

Define I/O information in the signal definition list. When the SCS and communication modules to be assigned to the I/O points are decided, define this information as well.

■ Editing the signal definition list

Follow these steps to edit the I/O information of the signal definition list:

1. Select the safety communication I/O list in System Structure Navigator and click [Check-out] on the tool bar of AD Organizer.
   The safety communication I/O list is checked out.
2. Select the signal definition list of Safety Communication I/O Editor and click [Add Row] on the tool bar.
   An I/O point is added to the signal definition list.
3. Enter I/O information into the cells in the signal definition list.

SEE ALSO For more information about setting items of the signal definition list, refer to:

"■ Setting items of Safety Communication I/O Editor" on page D2-8

● Editing the I/O information of the signal definition list

Follow these steps to edit the I/O information of the signal definition list:

1. Select a cell in the signal definition list.
   A dialog box appears, asking you to confirm the check-out.
2. Click [Yes].
   The I/O point is checked out and the icon for the item of [Checked-out Status] in the signal definition list changes.
3. Enter I/O information into the cells in the signal definition list.

TIP I/O points can be added to the signal definition list when Safety Communication I/O Editor is started for each P&ID group or target SCS.

SEE ALSO For more information about setting items of the signal definition list, refer to:

"■ Setting items of Safety Communication I/O Editor" on page D2-8

● Adding an I/O point to the signal definition list

Follow these steps to add I/O points to the signal definition list when the safety communication I/O list is not checked out:

1. Select an I/O point from the signal definition list.
2. Click [Add Row] on the tool bar.
   An I/O point is added above the selected I/O point and this added I/O point is checked out.

TIP I/O points can be added to the signal definition list when Safety Communication I/O Editor is started for each P&ID group or target SCS.

Initializing the I/O information of an edited signal definition list

Follow these steps to return the I/O information of an edited signal definition list to its initial values:

1. Select one or more cells of the signal definition list.
2. Right-click on the selected cell and select [Reset to Default].

Deleting an I/O point from the signal definition list

Follow these steps to delete an I/O point from the signal definition list:

1. Select the I/O point to delete from the signal definition list.
2. Click [Delete Row(s)] on the tool bar.
   The selected I/O points are deleted.

Entering basic information of I/O points

Enter the following items as basic information of the signal definition list:

- P&ID Tag
- I/O Type
- Signal Protocol
- I/O Tag
- Data type

Refer to the following table for settings of the Signal Protocol, I/O Type, and Data type.

Table D2.4-1 Relationship between the Signal Protocol and the Data type

Signal Protocol	I/O Type	Data type
MODBUS	AI AO	U16 I16 I32 F32
	DI DO	Bit
MODBUS (SLS)	AI AO	U16
	DI DO	Bit
PROFINET	AI	U8 I8 U16 I16 U32 I32 F32
PROFIsafe	AI	U8 I8 U16 I16 U32 I32 F32

As needed, define the following items for defining the data structure to obtain from the sub-system being connected to:

Program Group	:	The program group to which the I/O point belongs.
Communication Group	:	The communication definition group to which the I/O point belongs.
Position / Bit Position	:	The order of %WW and %XW in the communication definition group. Bit Position defines the bit position of %WW.
Comm Device & Address	:	The addresses of other devices.

Position denotes the order of %WW and %XW within a single communication group. Bit Position is the bit position when the Data type of DI or DO is Bit. These items are used when deciding the numbers for %WW and %XW.

TIP

%WW is an area assigned to communication modules for subsystem communication while %XW is an area assigned to communication modules for safety subsystem communication.

IMPORTANT

Do not define SLSEVENT, a data type used with ProSafe-SLS communication, in the signal area and configure only the program group definition and communication definition group. A signal cannot be associated with a communication group for the SLSEVENT definition. An error will occur when trying to save.

Entering I/O module assignment information of the signal definition

The following are precautions when assigning an I/O points of the signal definition to an I/O module.

- When assigning I/O points to an I/O module, define RS Project, SCS, Node Type, Node, IOM Category, IOM Type, and Slot. When these values are defined, the I/O points are copied to the Comm_I/O file under the SCS folder.
- When I/O information is entered to I/O points for which the I/O module assignment information is not defined, all I/O points for which I/O module assignment information is not defined are checked out. When I/O information is entered to I/O points for which the I/O module assignment information is defined, all I/O points which are assigned to the same SCS are checked out.

Purpose of user definition and changing user-defined name

In addition to the default setting items, 40 setting items that users can define freely are provided in the safety communication I/O list. I/O information that is included in the user-defined setting items is reference information. This I/O information is not reflected to the SCS project. However, when engineering by using iDefine, the user-defined I/O information is included in the ProSafe-RS I/O file. As such, we recommend that you configure the ID and other information that you want to refer to when creating an application logic by using iDefine here. If you assign an alias to a user-defined column, the user-defined column header of the ProSafe-RS I/O file that is exported to iDefine becomes the defined alias.

You can use the user-defined setting items as reference information when using the grid rules.

Any name can be specified for the user-defined setting items. Follow these steps to specify any name for the user-defined setting items:

1. From the sub menu of the safety communication I/O list, select [User Define Column Setting].
   The User Define Column Setting dialog box appears.

   The initial values of the setting item names are displayed in User Definition Column.

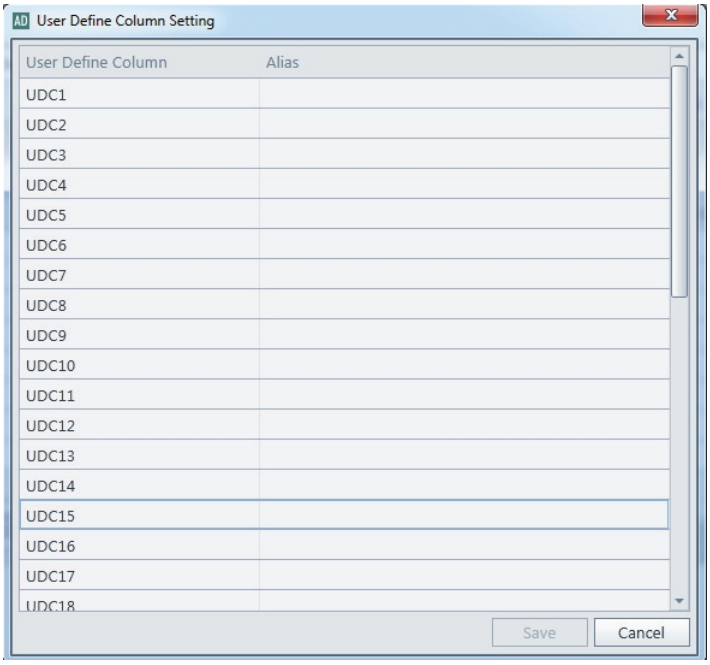

Figure D2.4-1 User Define Column Setting dialog box

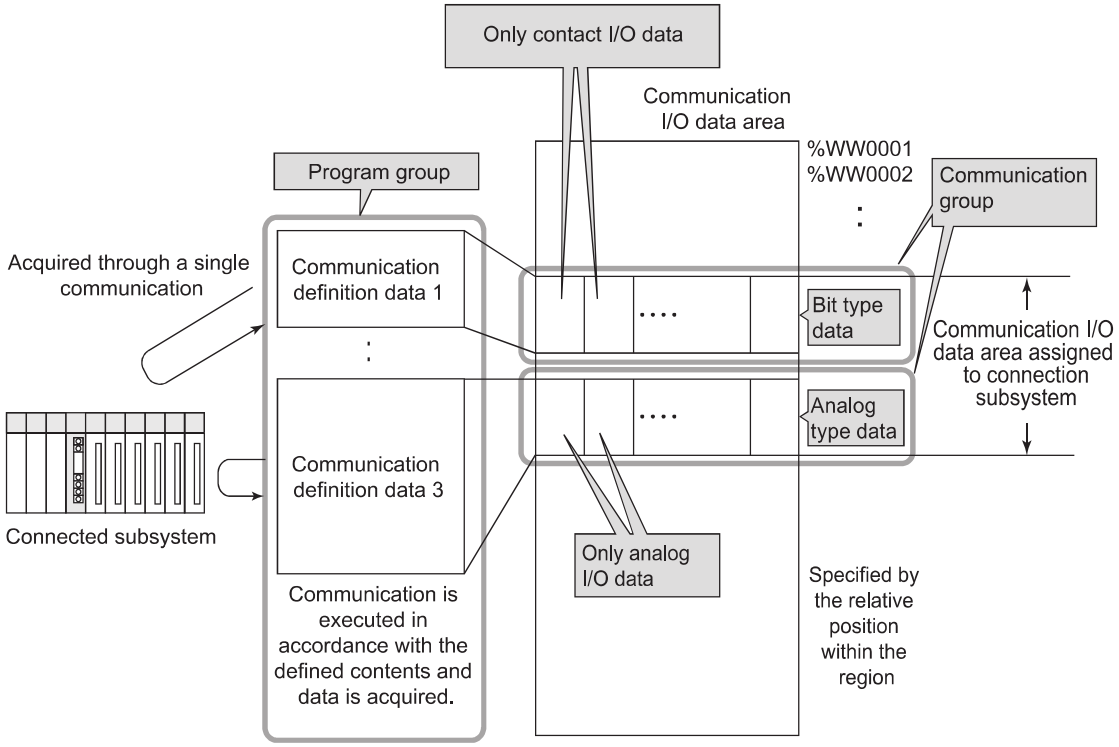
2. Enter the name that needs to be changed in [Alias], and click [Save].
   The new name is displayed in the user-defined setting item of the safety communication I/O list.

D2.5 Converting I/O information into a data structure that can be communicated with subsystems

This section describes how to convert I/O information into a data structure that can be communicated with subsystems being connected by using Safety Communication I/O Editor.

D2.5.1 Overview of definitions for communication with subsystems

In order to communicate with subsystems, after assigning a communication I/O data area for each subsystem being connected, you must set what kind of data to obtain from the connected subsystems and in which part of the connected subsystems the data will be written. With this setting, each assigned area is split into units of data which can be obtained or set with a single round of communication with the connected subsystem and then defined for how each of these will communicate by using Safety Communication I/O Editor. The following figure shows an overview of communication definitions for subsystems.



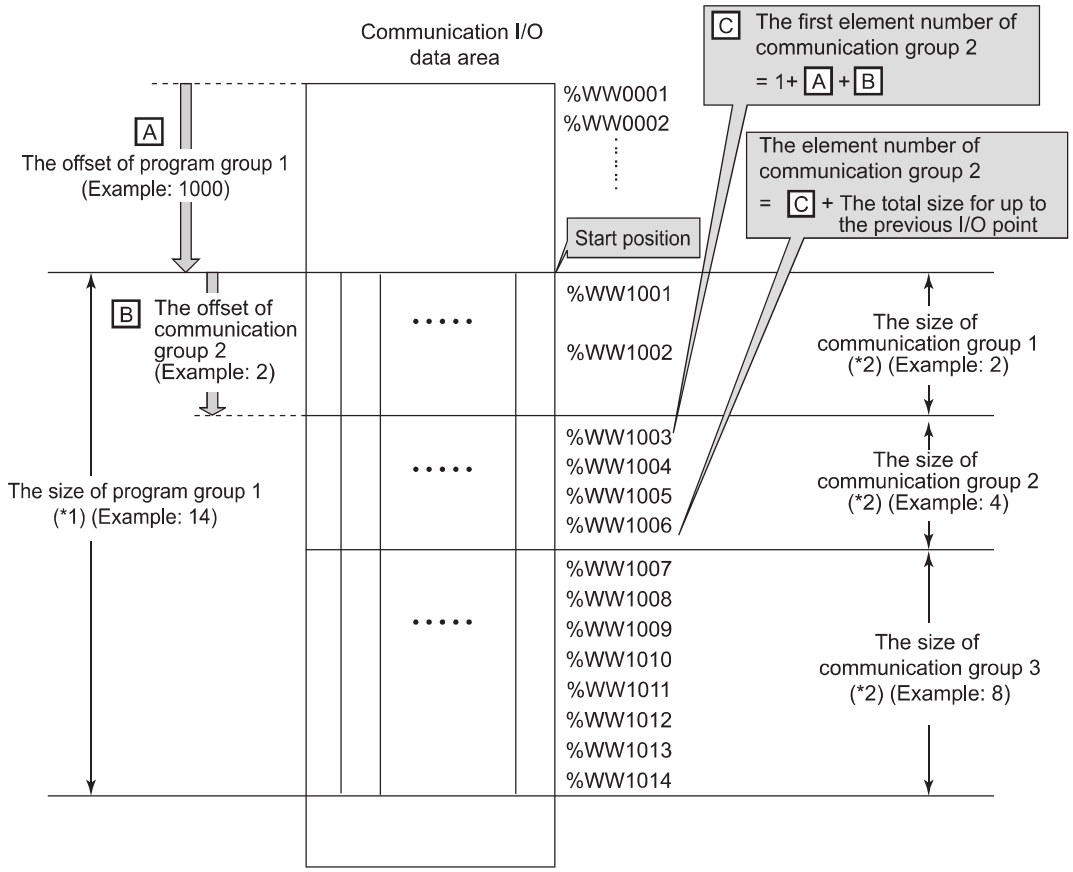


Figure D2.5.1-1 Overview of communication definitions

Element numbers in the communication I/O data area

The following figure shows an example of the assignment of element numbers in the communication I/O data area.

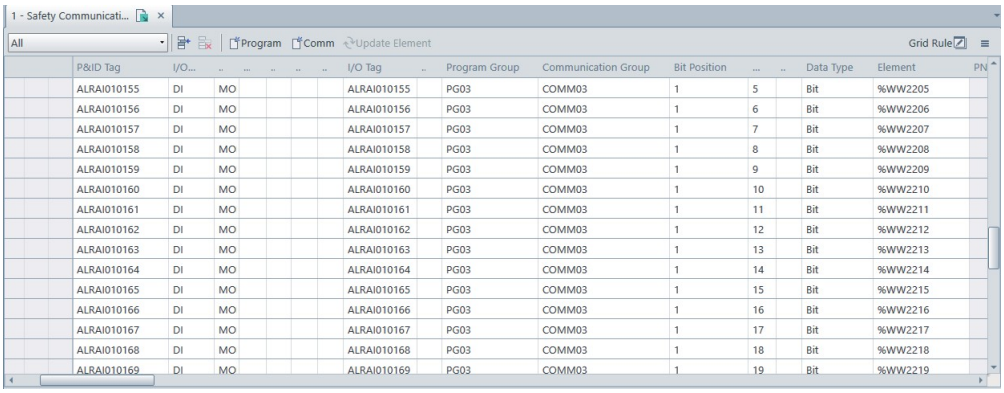
*1: The total size for the communication groups assigned to program group 1
*2: The total size for the I/O points assigned to each communication group

Figure D2.5.1-2 Example of assignment of element numbers in the communication module I/O data area

Flow of definitions for communication with subsystems

Follow these steps when converting I/O information into a data structure that can be communicated with subsystems:

1. Decide the data structure.
2. Assign a communication I/O data area for each subsystem being connected.
   - Define program groups.
   - Define communication groups.
3. Establish the element number of the communication I/O.



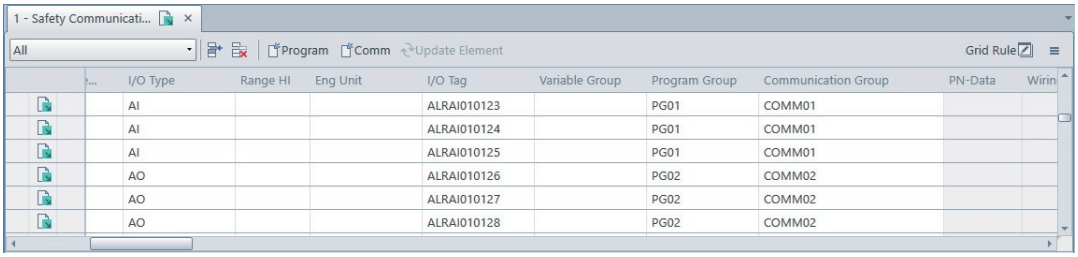
D2.5.2 Deciding the data structure

The data structures obtained from connected subsystems consist of bit-type data and analog-type data. This section describes the definitions of each type of data structure.

Defining the bit-type data structure

Bit-type data is configured of only the I/O points of bit data. Follow these steps to define the structure of this bit-type data:

1. In the signal definition list, enter the same program group name to the Program Group of the I/O points to include in a single set of the bit-type data.
2. In the signal definition list, enter the same communication group name to the Communication Group of the I/O points to include in a single set of the bit-type data.



P&ID Tag	I/O...	..	...	..	..	..	I/O Tag	..	Program Group	Communication Group	Bit Position	...	..	Data Type	Element	PN
ALRAI010155	DI	MO					ALRAI010155		PG03	COMM03	1	5		Bit	%WW2205	
ALRAI010156	DI	MO					ALRAI010156		PG03	COMM03	1	6		Bit	%WW2206	
ALRAI010157	DI	MO					ALRAI010157		PG03	COMM03	1	7		Bit	%WW2207	
ALRAI010158	DI	MO					ALRAI010158		PG03	COMM03	1	8		Bit	%WW2208	
ALRAI010159	DI	MO					ALRAI010159		PG03	COMM03	1	9		Bit	%WW2209	
ALRAI010160	DI	MO					ALRAI010160		PG03	COMM03	1	10		Bit	%WW2210	
ALRAI010161	DI	MO					ALRAI010161		PG03	COMM03	1	11		Bit	%WW2211	
ALRAI010162	DI	MO					ALRAI010162		PG03	COMM03	1	12		Bit	%WW2212	
ALRAI010163	DI	MO					ALRAI010163		PG03	COMM03	1	13		Bit	%WW2213	
ALRAI010164	DI	MO					ALRAI010164		PG03	COMM03	1	14		Bit	%WW2214	
ALRAI010165	DI	MO					ALRAI010165		PG03	COMM03	1	15		Bit	%WW2215	
ALRAI010166	DI	MO					ALRAI010166		PG03	COMM03	1	16		Bit	%WW2216	
ALRAI010167	DI	MO					ALRAI010167		PG03	COMM03	1	17		Bit	%WW2217	
ALRAI010168	DI	MO					ALRAI010168		PG03	COMM03	1	18		Bit	%WW2218	
ALRAI010169	DI	MO					ALRAI010169		PG03	COMM03	1	19		Bit	%WW2219	

Figure D2.5.2-1 Bit-type data structure definition

Defining the analog-type data structure

Analog-type data is configured of only the I/O points of the same data type amongst analog I/O data. Follow these steps to define the structure of this analog-type data:

1. In the signal definition list, enter the same program group name to the Program Group of the I/O points to include in a single set of the analog-type data.
2. In the signal definition list, enter the same communication group name to the Communication Group of the I/O points to include in a single set of the analog-type data.

...	I/O Type	Range HI	Eng Unit	I/O Tag	Variable Group	Program Group	Communication Group	PN-Data	Wirin
	AI			ALRAI010123		PG01	COMM01		
	AI			ALRAI010124		PG01	COMM01		
	AI			ALRAI010125		PG01	COMM01		
	AO			ALRAI010126		PG02	COMM02		
	AO			ALRAI010127		PG02	COMM02		
	AO			ALRAI010128		PG02	COMM02		

Figure D2.5.2-2 Analog-type data structure definition

D2.5.3 Defining program groups

By defining program groups, you can configure I/O information for each connected subsystem. A maximum of 12 program groups can be defined. The breakdown is as follows:

- Up to 4 subsystem communication I/O (Models: ALR111M/ALR121M/ALE111M) groups
- Up to 8 safety subsystem communication (Model name: S2LP131) groups

Follow these steps to define the program groups:

1. Click [Program] on the tool bar of Safety Communication I/O Editor.
   The program group set with Program Group of the signal definition list is added to the program group definition list, and the I/O information is configured for each connected subsystem. At this time, the default value for Size is 2 while the default value for Offset is blank.

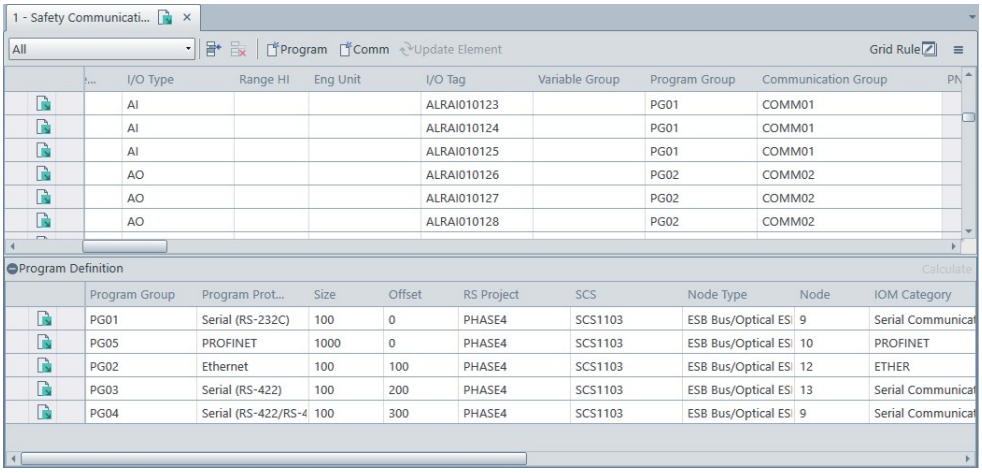


Figure D2.5.3-1 Program group definition

2. On the tool bar of AD Organizer, click [Save].

SEE ALSO For more information about setting items of the program group definition list, refer to:

"■ Setting items of Safety Communication I/O Editor" on page D2-8

D2.5.4 Defining communication group

By defining communication groups, you can configure I/O information for each set of communication definition data. Follow these steps to define the communication groups:

1. Click [Communication] on the tool bar of Safety Communication I/O Editor.
   The communication group set with Communication Group of the signal definition list is added to the communication group definition list and the I/O information is configured for each set of communication definition data. At this time, the default value for Size is 1 while the default value for Offset is 0.

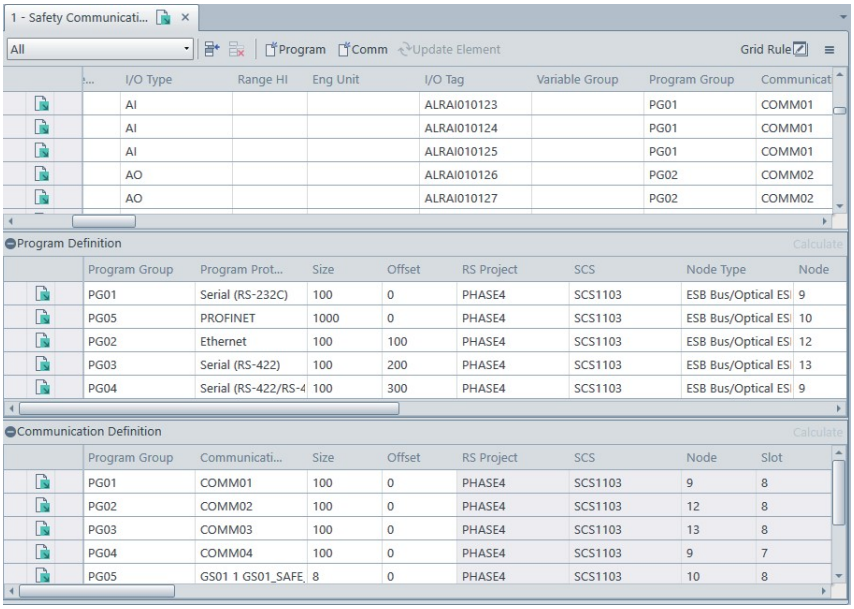

Figure D2.5.4-1 Communication group definition

TIP

The maximum number of communication groups that can be assigned to a single program group is as follows:

- 128 per program group for program protocols other than PROFINET
- With SCSP3, program groups for the PROFINET protocol can be defined in addition to the above making the maximum 200 per program group

2. On the tool bar of AD Organizer, click [Save].

SEE ALSO

For more information about setting items of the communication group definition list, refer to:

"■ Setting items of Safety Communication I/O Editor" on page D2-8

D2.5.5 Fixing the element numbers of the communication I/O

After defining or editing the basic information, I/O module assignment information, and data structure information with the signal definition list, you must fix the element numbers of the communication I/O.

IMPORTANT

- After defining RS Project and SCS of the I/O points for which to fix element numbers with the signal definition list, start Safety Communication I/O Editor by selecting the target SCS in the System Structure Navigator.
- When Fix Element of the signal definition list is set to [Yes], I/O information cannot be changed. If you want to change the I/O information, change Fix Element to [No].

Follow these steps to decide the element numbers of communication I/O:

1. Click [Calculate] on the communication group definition list.
   The size of the communication group is calculated and appears under Size in the communication group definition list.
2. Check Size in the communication group definition list and enter the size of the communication group under Offset.
3. Click [Calculate] on the program group definition list.
   The size of the program group is calculated and appears under Size in the program group definition list.
4. Check Size in the program group definition list and enter the size of the program group under Offset.
5. Click [Update Element] on the tool bar of Safety Communication I/O Editor.
   The consistency of the I/O information is checked and element numbers of the communication I/O are set.

TIP

When Fix Element of the signal definition list is set to [Yes], the element numbers of the communication I/O become fixed.

SEE ALSO

For more information about setting items of the safety communication I/O list, refer to:

"■ Setting items of Safety Communication I/O Editor" on page D2-8

D2.5.6 Procedure for creating and wiring communication I/O variables

A communication I/O is wired to an instance of a subsystem communication I/O FB or fire and gas communication FB. The FB instance is defined as a global variable, local variable, or parameter of a user-defined FB instance.

Global variables are defined by using Safety Communication I/O Editor of AD Organizer and can be created when the reflection process is run for the target SCS by using Generation Manager.

I/O Tag in the signal definition of the safety communication I/O list will become the variable name in Dictionary View after reflection onto the SCS project. In addition, this will be the variable name that is wired in Communication I/O Builder.

The description shown in the following table can be used as a method for describing the variable name to be wired.

Table D2.5.6-1 How to describe a variable name

Variable name	Scope	Description
VAR1	Global (*1)	Global variable
VAR2@PROG1	PROG1	Local variable of a function of PROG1
FB01.VAR3	Global (*1)	Parameter VAR3 of instance FB01 of a user-defined function block
FB01.VAR3@PROG1	PROG1	Parameter VAR3 of user-defined FB instance FB01 locally defined to the function of PROG1
FB01.FB2.VAR3	Global (*1)	Parameter VAR3 of instance FB2 of a user-defined FB used within instance FB01 of a user defined FB (limit for nesting of FB)

*1: In order to handle variables other than global variables with the safety communication I/O list, the information of the variables and parameters of subsystem communication I/O FB included in the POU created with iDefine or SCS Manager is required. In order to handle this information with the safety communication I/O list, do not describe global variables in the Wiring column of signal definitions.

TIP

The options for the Wiring column are updated upon obtaining information from the iDefine setting file and SCS project at the timings shown below when the safety communication I/O list for an SCS is opened in Safety Communication I/O Editor:

- When the safety communication I/O list is opened
- When Refresh is clicked

When a local variable or user-defined FB instance parameter has been specified in the Wiring column of the signal definition, Generation Manager does not create a global variable described in the I/O Tag column. Local variables or user-defined FB instance parameters created with iDefine or SCS Manager are used. Variables defined with iDefine cannot be edited with SCS Manager.

Variables other than global variables are applied to communication definitions using the applicable communication module in Safety Communication I/O Editor. The applicable variables and parameter types are the FB for the communication of each.

These variables and FB parameters can be wired to communication I/O by defining Wiring of Signal Definition in the Safety Communication I/O Editor.

This section describes the work flow for creating all FB instances as global variables and wiring them to communication I/Os, then wiring some of the communication I/Os to local variables or FB parameters.

1. The default value for Wiring of the signal definition is [(Global)]. Select [(Global)] for Wiring of the signal definition, and then run the reflection process with Generation Manager. Global variables are created in Dictionary View with the variable names specified in I/O Tag.

   If Element is set, the relevant variable is set in Variable Name for the specified data area on the Comm. I/O Wiring tab of Communication I/O Builder.

TIP

The options for Wiring are updated upon obtaining information from the iDefine setting file and SCS project at the timings shown below when the safety communication I/O list for an SCS is opened in Safety Communication I/O Editor:

- When the safety communication I/O list is opened
- When [Refresh] is clicked

2. Create local variables and parameters of user-defined FB instances with SCS Manager or iDefine, and import the iDefine-config file containing the definitions to AD Organizer. The local variables and parameters of user-defined FB instances are displayed in Wiring.
3. Select the local variable or the parameter of a user-defined FB instance you want to wire.

IMPORTANT

Wiring is editable when Safety Communication I/O Editor is started for a selected SCS. When the editor is started upon selecting I/O-list or RS project, Wiring is read-only.

4. Using Generation Manager, run the reflection process.
   The global variables that you created in step 1 are deleted.

   If Element is set, the local variable or parameter of a user-defined FB instance specified in Wiring is set in Variable Name for the specified data area on the Comm. I/O Wiring tab of Communication I/O Builder.

D2.6 Importing I/O information into the safety communication I/O list

You can import a list of I/O information obtained from a plant designer into the safety communication I/O list. When the list of I/O information contains program group definitions and communication group definitions, these are imported as well.

TIP

You can import I/O information into the safety communication I/O list when Communication I/O Editor is started for each P&ID group.

Import file format

Create the file to be imported in the following format:

- File format
  .xlsx file for Microsoft Excel
- Sheet name
  Set a name of your choice.
- Sheet description
  Lines of setting item names and I/O information corresponding to these items must be entered. Enter one line of I/O information at a time for each type of I/O information. The following shows an example of the content of the sheet.

Types of I/O information

Names of setting items in the I/O information list (Header row of the list to be imported)

		A	B	C	D	E	...	BQ	BR	...	DD	DE	...	DP
1			Management Information		Common Information		Communication I/O definition Information	Reference Information (Not RS Generation)				I/O List Label		
2	ROW_TYPE		Area	P&ID Sheet	P&ID Tag	I/O Type	···	UDC1	UDC2	···	UDC40	P&ID Group	···	F_Par_CRC
3			XXX	XXX	XXX	XXX	···	XXX	XXX	...	XXX	XXX	···	XXX
4	SG		XXX	XXX	XXX	XXX	···	XXX	XXX	···	XXX	XXX	···	XXX
5	PG						···			...			···	
6	CG						···			...			···	XXX

I/O information of different types of I/O information

Figure D2.6-1 Example of sheet description

The following table shows the input values corresponding to the types of I/O information.

Table D2.6-1 Types and input values of I/O information

Type of I/O information	Input value
Signal definition	SG or blank
Program group definition	PG
Communication group definition	CG

TIP

When a value other than SG, PG, or CG is entered in ROW_TYPE, the type of I/O information being imported will be interpreted as signal definition.

SEE ALSO

For more information about types of I/O information, refer to:

D2.5, “Converting I/O information into a data structure that can be communicated with subsystems” on page D2-21

Importing the I/O information list

You need to prepare the I/O information file in the xlsx format of Microsoft Excel. Follow these steps to import the I/O information file in the xlsx format for Microsoft Excel:

1. Click [Sub menu] in Safety Communication I/O Editor and select [Import].
   The Import wizard appears.
2. In the field for File, specify the file in the xlsx format of Microsoft Excel containing the I/O information to be imported.
   Sheet Name shows the sheet name of the I/O information list, Header Row Position shows the row number in which the setting item is entered, and Target P&ID Group shows the P&ID group name that is included in the I/O information list.

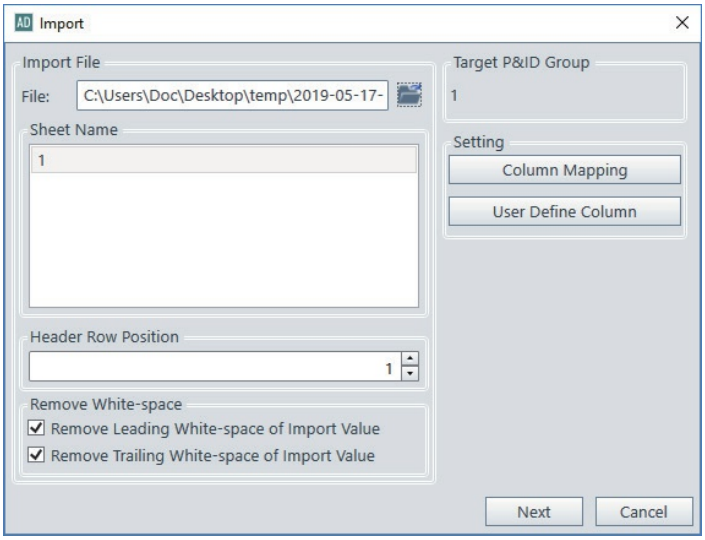

Figure D2.6-2 Import wizard

3. Select the sheet to be imported in Sheet Name.
4. Enter the row number in which the setting item is entered in Header Row Position.
5. Set the following details in Settings if necessary. More specific instructions are given later.
   - If the setting item of the I/O information list to be imported does not match the setting item of the signal definition list, click [Column Mapping] to map the setting items.
   - If the setting item of the I/O information list to be imported cannot be mapped to the setting item of the signal definition list, click [User Define Column] and, after adding the new setting item to the communication I/O list, perform the mapping to these new items.
6. Select the [Remove Leading White-space of Import Value] or [Remove Trailing White-space of Import Value] check boxes optionally.
7. Click [Next].
   The screen will switch to the Comparison and Setting screen.
8. Select either [All Check (Add/Update/Delete)] or [Part Check (Add/Update)].
   All the rows in the list of I/O information are imported.

   If you have selected [All Check (Add/Update/Delete)], the rows that are not available in the I/O information list are deleted from the safety communication I/O list.

   If you have selected [Part Check (Add/Delete)], the rows that are not available in the I/O information list are not deleted from the safety communication I/O list.
9. Click [Finish].
   The I/O information list is imported, and the safety communication I/O list is checked out.

Mapping the setting items of the I/O information list to the setting items of the signal definition list

The procedures are the same as mapping of the safety I/O list.

SEE ALSO For more information about procedures for mapping the safety I/O list, refer to:

- "■ Mapping the setting items of the I/O information list to the setting items of the safety I/O list" on page D1-17
- "■ Modifying the mapping information in AD Organizer that has been upgraded to version R4.05 or later" on page D1-18

For more information about importing and exporting mapping information, refer to:

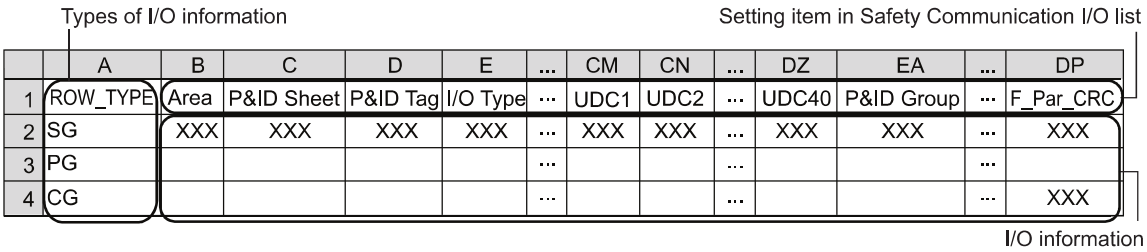
- "■ Exporting mapping information" on page D1-18
- "■ Importing mapping information" on page D1-18

Reflecting the I/O information upon comparing the information from before and after the import

The procedures are the same as with Safety I/O Editor.

SEE ALSO For more information about comparing the safety communication I/O lists from before and after an import, and reflecting the list , refer to:

D1.4.3, "Comparing and reflecting the I/O information before and after import" on page D1-19



D2.7 Exporting the I/O information in the safety communication I/O list

You can export the information of the safety communication I/O list by operating Safety Communication I/O Editor.

Export file format

The exported file is created in the following format.

- File format
  .xlsx format of Microsoft Excel
- Sheet name
  It will be the P&ID group name.
- Sheet description
  Lines of setting item names and I/O information corresponding to these items will be exported. One line of I/O information is exported for each type of I/O information.

	A	B	C	D	E	...	CM	CN	...	DZ	EA	...	DP
1	ROW_TYPE	Area	P&ID Sheet	P&ID Tag	I/O Type	···	UDC1	UDC2	···	UDC40	P&ID Group	···	F_Par_CRC
2	SG	XXX	XXX	XXX	XXX	···	XXX	XXX	...	XXX	XXX	···	XXX
3	PG					···			...			···	
4	CG					···			...			···	XXX

Figure D2.7-1 Sheet description

TIP

If you assign an alias to a user-defined column, the Setting item in Safety Communication I/O list that corresponds to the user-defined column becomes an alias.

The following table shows the relationship between the values of ROW_TYPE and the types of I/O information.

Table D2.7-1 Values of ROW_TYPE and types of I/O information

ROW_TYPE value	Type of I/O information
SG	Signal definition
PG	Program group definition
CG	Communication group definition

D2.8 Saving and checking in the safety communication I/O list

You can save and check-in the safety I/O list. By performing this operation, the safety communication I/O list is stored in the AD project.

Saving the safety communication I/O list

Follow these steps to save the safety communication I/O list:

1. Select Safety Communication I/O Editor.
2. On the tool bar of AD Organizer, click [Save].

TIP

- When the I/O module assignment information of the safety communication I/O list is edited, the safety communication I/O list (Comm_I/O) under the SCS of the assignment destination is automatically checked out and the content of the definition is reflected.
- When the Safety Communication I/O Editor is in the Deviation mode, you cannot save the safety communication I/O list.

Performing check-in of the safety communication I/O list

By using the Check-in window, check in the defined safety communication I/O list.

The icon shown for the item of [Checked-out Status] in the safety communication I/O list changes.

SEE ALSO For more information about operations for a check-in, refer to:

D2.8, “Saving and checking in the safety communication I/O list” on page D2-34

D2.9 Engineering after changing the safety communication I/O list

The user can proceed with the engineering by using the safety communication I/O list before the I/O information is fixed. Once the information is fixed, the changes can be reflected in the engineering data by loading the updated safety communication I/O list at a later stage.

If the safety communication I/O list is modified, you need to load the safety communication I/O list into Safety Communication I/O Editor, check the differences, and reflect them onto the database.

After the safety communication I/O list is imported, you need to use IOM Definition Editor to define the IOM.

After the changes are reflected to the SCS project, you must return to the previous step of engineering and proceed with the task according to the updated details.

D3. Input/output module configuration definition

The process of determining the IOM arrangement in SCS and the channel arrangement of IOM based on the I/O information list from the plant designer is referred to as I/O module assignment.

By using AD Organizer, you specify the SCS node and IOM relevant to each P&ID tag and their connection information based on the information that is displayed in Safety I/O Editor or Safety Communication I/O Editor.

For defining the I/O module configuration, the IOM Definition Editor is used to set the properties of the node and the I/O module (referred to as IOM).

The following types of properties are set.

- Node properties
- Basic IOM properties
  - IOM type
  - RS project name
  - Station name
  - Node number
  - Slot number
  - Other properties (redundancy, IOM comments, output type etc.)
- Advanced properties for each IOM type

D3.1 Overview of the node and I/O module creation

By using the IOM Definition Editor, you can assign nodes to the specified SCS, or assign I/O modules to the specified node. You can perform the following tasks with the IOM Definition Editor:

- Creating nodes and I/O modules based on the safety I/O list or safety communication I/O list
- Creating nodes and I/O modules without using the safety I/O list or safety communication I/O list
- Editing the node and I/O module

After creating nodes and I/O modules, save and check in them.

D3.2 Starting the IOM Definition Editor

Depending on the operation purpose, the method to start the IOM Definition Editor varies.

- Perform one of the following operations to start the Safety I/O Editor:
  - When creating or editing nodes and I/O modules of an RS project, right-click the target RS project in the System Structure Navigator and select [IOM Definition Editor].
  - When creating or editing nodes and I/O modules of an SCS, right-click the target SCS in the System Structure Navigator and select [IOM Definition Editor].
  - When editing a node, double-click [Node_definition] under the I/O module folder in the System Structure Navigator.
  - When editing a node, double-click [IOM_definition] under the I/O module folder in the System Structure Navigator.

  The IOM Definition Editor appears in the document window area of AD Organizer.

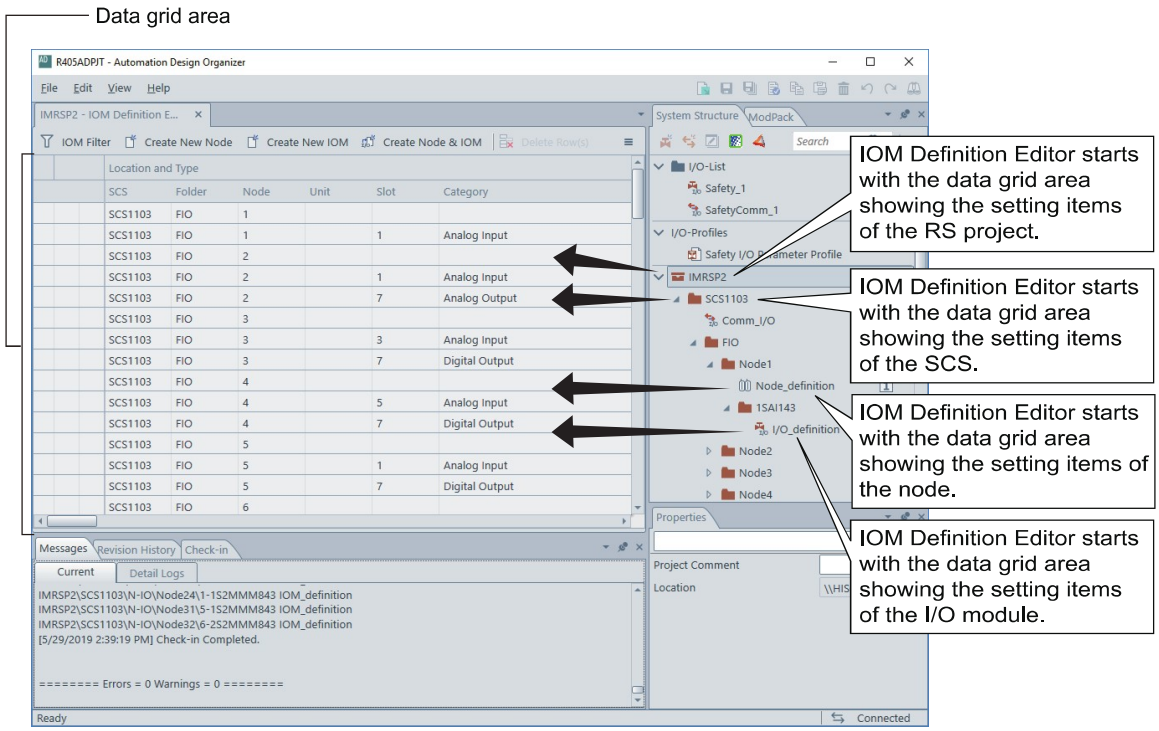


Figure D3.2-1 IOM Definition Editor

TIP

When the IOM Definition Editor is started, the source for which you have started the editor appears in the window title.

D3.3 Displaying for each specified setting item

You can switch the display of the data grid area of the IOM Definition Editor for each specified setting item. You need to perform the following operations to switch the display.

1. Click the [IOM Filter] button on the IOM Definition Editor tool bar.
   The Property Group Selection dialog box appears.

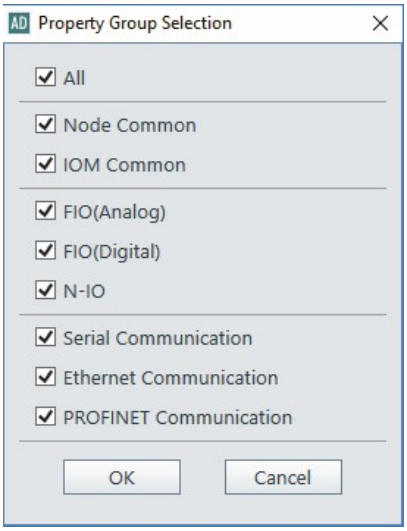

Figure D3.3-1 Property Group Selection dialog box

2. Select the check box of the setting item that needs to be displayed in the data grid area, and click the [OK] button.
   Only the selected setting item is displayed in the data grid area.

D3.4 Creating the node and I/O module

There are two ways to create the node and I/O module.

- Creating the node and I/O module based on safety I/O list
  You need to create the node and I/O module after defining the I/O module assignment information.
- Creating nodes and I/O modules without using the safety I/O list and safety communication I/O list
  You need to define the I/O module assignment information in the safety I/O list and safety communication I/O list after creating the nodes and I/O modules.

TIP

It is necessary to manually enter the settings of SEC401, SEC402, L1EC401, L1EC402, S2EN402, S2EN404, and the communication module based on the node settings.

It is also necessary to create the CPU node (FIO node number 1) manually even if you are creating nodes and I/O modules based on the safety communication I/O list.

Creating the node and I/O module based on safety I/O list

Follow these steps to create the node and I/O module based on the safety I/O list:

1. Click the [Create Node & IOM] button on the IOM Definition Editor tool bar.
   The Create Node & IOM window appears, and the I/O module assignment information is displayed in the list.

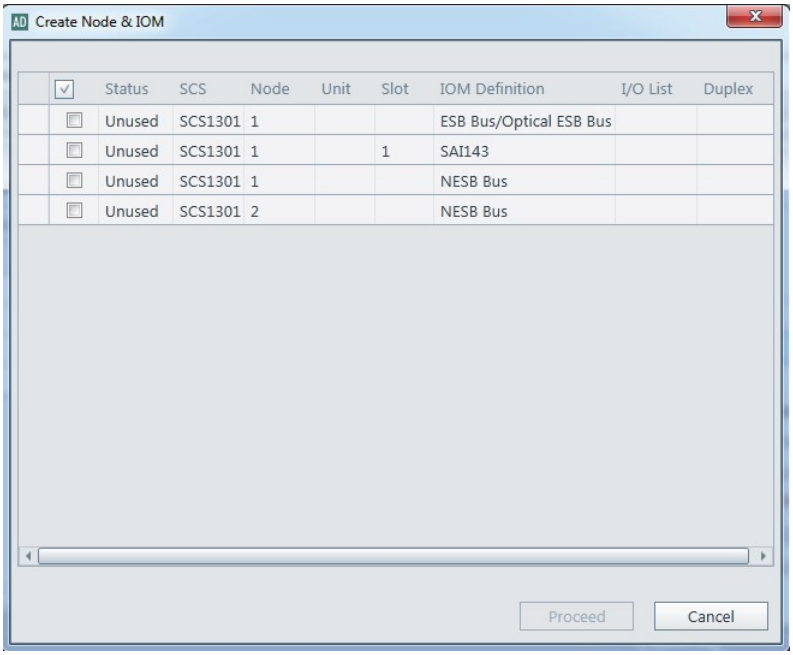

Figure D3.4-1 Create Node & IOM window

2. Select the check box of the assignment information of the node and I/O module that are to be created or deleted, and click [Proceed].
   The SCS name, node type, node number, slot number, unit number, I/O module category, and the I/O module type that are defined in the safety I/O list are assigned, and the node and I/O module are created.

   The node and I/O module that are created are added to the data grid area of the IOM Definition Editor.

TIP

- You can check whether the assignment information of the node and I/O module that are to be created is defined in the safety I/O list or not in Status.
- If the I/O module assignment information is defined in the safety I/O list, New is displayed. If the I/O module assignment information is not defined in the safety I/O list, and if the node and I/O module are created manually by using the IOM Definition Editor, Unused is displayed.
- When the check box of the assignment information of the node and I/O module, whose Status is Unused, is selected, and the [Proceed] button is clicked, the specified node and I/O module are deleted.

Setting items and status when creating nodes and IOMs based on the safety I/O list

The following table describes the setting items for creating nodes and IOMs based on the safety I/O list.

Table D3.4-1 Setting items for creating nodes and IOMs based on the safety I/O list

Setting item	Description
SCS	Location information of node or IOM
Node	Location information of node or IOM
Unit	Location information of node or IOM (Only N-IO)
Slot	Location information of node or IOM
IOM Definition	Detailed description is displayed in the tool tip
I/O List	Signal type of I/O
Duplex	Yes, for redundant Blank, for non-redundant

The following table describes the status when creating nodes and IOMs based on the safety I/O list.

Table D3.4-2 Status of the Create Node & IOM window

Status	Description
New	The I/O module assignment information is defined in the safety I/O list
Unused	The I/O module assignment information is not defined in the safety I/O list, and the node and I/O module are created manually by using the IOM Definition Editor

Creating a node

Follow these steps to create a node without using the safety I/O list:

1. Click the [Create New Node] button on the IOM Definition Editor tool bar.
   The Create Node dialog box appears.

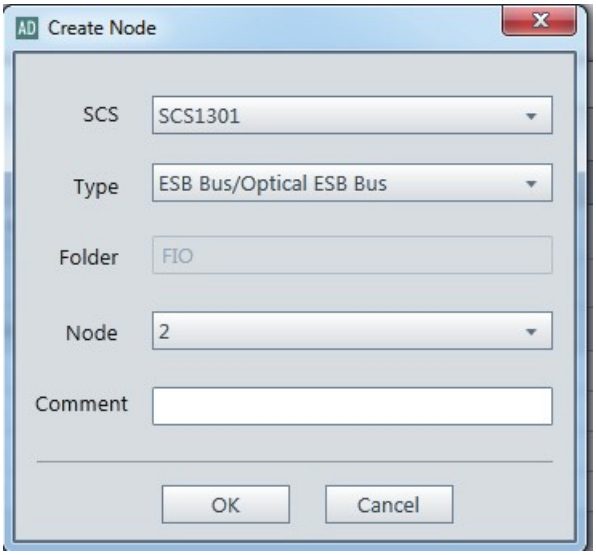

Figure D3.4-2 Create Node dialog box

2. Click the [OK] button after entering the setting items.
   The Create Node dialog box closes, and the node is added to the data grid area of the IOM Definition Editor.

Creating an I/O module

Follow these steps to create an I/O module without using the safety I/O list:

TIP

It is necessary to manually enter the settings of SEC401, SEC402, L1EC401, L1EC402, S2EN402, S2EN404, and the communication module based on the node settings.

1. Click the [Create New IOM] button on the IOM Definition Editor tool bar.
   The Create IOM dialog box appears.

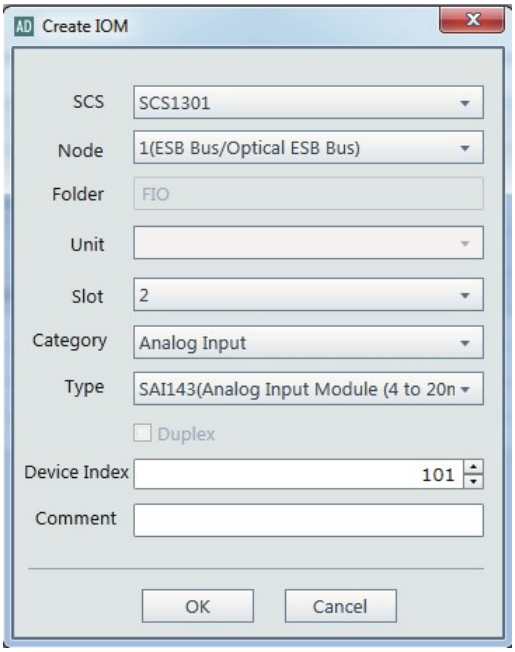

Figure D3.4-3 Create IOM dialog box

TIP

When [Duplex] check box is selected, the adjacent slot is occupied when the I/O module is created.

The initial values of [Device index] appear based on the node number, unit number, and slot number of the I/O module. The rules are as follows according to the I/O module type. The unit number of the I/O module installed in the FIO node is always 0.

- For FIO
  Rule: Node number + 0 + Slot number
  Example: For the module in node 10, slot 1: 1001
- For N-IO
  Rule: Node number + Unit number + Slot number
  Example: For the module in node 1, unit 1, slot 1: 111

An error occurs if you define duplicate values from other I/O modules as the device index.

2. Click the [OK] button after entering the setting items.
   The Create IOM dialog box will close, and the I/O module is added to the data grid area of the IOM Definition Editor.

Setting items when creating nodes and I/O modules without using the safety I/O list or safety communication I/O list

The types of I/O modules that you can add vary depending on the type of the node.

The following table shows the relationship between the SCS type and the node that can be added.

Table D3.4-3 Relationship between the SCS type and the node that can be added

Node type	Type of SCS (*1)					
	S2SC70x		L1SC70x	SSC60x	SSC50x	SSC57x
	FIO	N-IO	FIO	FIO	FIO	FIO
SNB10D	Yes	No	No	Yes	Yes	Yes
L1NB10D	No	No	Yes	No	No	No
S2NN30D	No	Yes	No	No	No	No

*1: Yes: Can be added.
No: Cannot be added.

The following table describes the setting items for creating a node.

Table D3.4-4 Setting items for creating a node

Setting item	Description
SCS	Name of the SCS in which the node is installed
Type	Type of the node that is added Set ESB Bus/Optical ESB Bus, or N-ESB Bus
Folder	IOM folder Set FIO, or N-IO
Node	Node number
Comment	Node related comments

The following table describes the setting items for creating an I/O module.

Table D3.4-5 Setting items for creating an I/O module

Setting item	Description
SCS	Name of the SCS in which the node is added
Node	Node number

Continues on the next page

Table D3.4-5 Setting items for creating an I/O module (Table continued)

Setting item	Description
Folder	Name of the folder in which the node is installed
Unit	Unit number
Slot	Slot number
Category	Category of the IOM that is added
Type	Type of the IOM that is added
Duplex	Make the adjacent IOM dual redundant
Device index	Device index of IOM
Comment	Node related comments

D3.5 Editing the setting items of the node and I/O module

Follow these steps to edit the setting items of the node and I/O module:

1. In the IOM Definition Editor list, double-click an editable cell.
   A dialog box appears, asking you to confirm the check-out.
2. Click [Yes].
   The corresponding node definitions and I/O module definitions are checked out, and check-out icons appear in the list.
3. In the cells of the IOM Definition Editor list, enter the values of the setting items of the node and I/O module.

TIP

If you select one or multiple columns of the device index, right-click, and select [Reset to Default], the values are reset to the initial values of the device index. The values of the node, unit, and slot on which the I/O module is installed are reflected on the initial values of the device index.

4. The Duplex setting of I/O modules must match the setting in the safety I/O list. To change the Duplex setting of the I/O module in the IOM Definition Editor, follow these steps:
   a. In the System Structure Navigator, select a file under the I/O-List folder and start the Safety I/O Editor. Clear [RS Project] of the definitions for which you want to change the Duplex setting and perform a check-in.
   b. In the list of the IOM Definition Editor, select the row of the target I/O module, change the [Duplex] setting, and then perform a check-in.
   c. In the System Structure Navigator, select a file under the I/O-List folder and start the Safety I/O Editor. Restore the [RS Project] that you cleared in step a and perform a check-in.

Bulk editing of the IOM definition

The user can perform bulk definition of multiple IOM definition elements by using the design results of Safety I/O Editor or Safety Communication I/O Editor.

Checking/resolving the issues in the I/O module assignment information

You can check the details of the I/O module assignment information by utilizing the check function of the grid rules by using Safety I/O Editor or Safety Communication I/O Editor.

If issues are found in the I/O module assignment information, you can correct the design related details by using Safety I/O Editor or Safety Communication I/O Editor, or create and edit the node and IOM which the design information requests by using IOM Definition Editor.

Generating the I/O module assignment information by using IOM

You need to perform the following procedure.

1. Click the [Create Node & IOM] button on the IOM Definition Editor.
   The generation and update process of the IOM are executed.

   Once the generation and update process of the IOM end, the IOM Definition Editor appears. The default value is applied to the properties of the node and IOM that are created based on the design information.
2. After setting the node and IOM properties, click [Save] in the IOM Definition Editor.
3. Check in the changes from the Check-in window.
   The editing is completed, and the details in the System Structure Navigator are updated.

D3.6 Deleting the node or I/O module

Follow these steps to delete the node or the I/O module:

1. Select the node or the I/O module in the IOM Definition Editor, and click the [Delete Row] button on the IOM Definition Editor tool bar.
   When the node is deleted, the IOM under the node is also deleted. When the IOM is deleted, the information is not deleted from the safety I/O list, and only the IOM data is deleted.
2. Check in the changes from the Check-in window.
   The details in the System Structure Navigator are updated.

D3.7 Exporting information from IOM Definition Editor

The definitions including the hidden columns and rows in IOM Definition Editor are exported to a CSV file.

Exporting the IOM definition information

Follow these steps to export the IOM Definition Editor definition:

1. From the sub menu of the IOM Definition Editor, select [Export].
   The Folder selection dialog box appears.
2. Enter the name of the file to be exported.
3. Specify the save destination and click [OK].

TIP

- If you export while editing, the edited contents are exported.
- While exporting, progress and result of the process is displayed in the Message Window.
- The file is exported in CSV format.

D3.8 Importing information to IOM Definition Editor

You can import the CSV file that you exported from IOM Definition Editor in to IOM Definition Editor. By importing, you can change the properties of existing nodes and I/O modules. You can change the properties only when defining nodes or I/O modules whose values match with those in the following columns: SCS, folder, node number, unit, slot, category, and type.

You cannot add nodes or I/O modules by importing. Also you cannot delete nodes or I/O modules by importing.

Importing the IOM definition information

Follow these steps to import a CSV file:

1. In IOM Definition editor, right-click a row to be imported, and select [Check-out].
2. From the sub menu of the IOM Definition Editor, select [Import].
   The Folder selection dialog box appears.
3. Select the file you want to import, and click [OK].

TIP

While importing, the progress and result of the process is displayed in the Message Window.

D3.9 Saving the node and I/O module and performing check-in

You can save the node and I/O module and perform a check-in. By doing this operation, the node and the I/O module are stored in the AD project.

Saving the node and I/O module

Follow this step to save the node and the I/O module:

- On the tool bar of AD Organizer, click [Save] while the focus is on the IOM Definition Editor.

Checking in the node and I/O module

- In the Check-in window, check in the created node and I/O module.

D4. Overview of RS generation

The reflection process and the SCS project build process are available as part of RS generation.

After creating engineering data by using iDefine, import the iDefine-config file with AD Organizer and check in before running the reflection process.

- Reflection process
  The safety I/O list, safety communication I/O list, and IOM information that were edited in AD Organizer and the iDefine-config file are acquired from the AD Server and converted into an SCS project file (hereinafter referred to as a conversion). Once the reflection process has been successfully completed, the data of the safety I/O list, safety communication I/O list, IOM information, and iDefine-config file are reflected onto the SCS database.

  The iDefine-config file is obtained when engineering is performed using iDefine.

- Build process of the SCS project
  You can run the SCS project build. If the reflection process is required, the build process is run after the reflection process is automatically run. The SCS project build process builds the entire SCS project while including the following engineering data in addition to the setting items related to the safety I/O list, safety communication I/O list, and IOM information:

  - Function blocks edited with SCS Manager or other builders
  - Subsystem settings
  - Engineering data in the iDefine-config file

  Be sure to perform the build process of the SCS project when downloading the data to SCS.

The target information for RS generation is as follows:

- Safety I/O list created by the Safety I/O Editor
- Safety communication I/O lists created with Safety Communication I/O Editor
- IOM information created by the IOM Definition Editor
- iDefine-config file

The related builders are as follows:

- Dictionary View (Variable)
- I/O Wiring View
- I/O Parameter Builder
- Tag Name Builder
- Link Architecture View
- Multi-Language Editor
- Communication I/O Builder

D4.1 Reflection process

Conversion and import are performed as part of the reflection process.

Conversion

When engineering is performed with the safety I/O list, safety communication I/O list, IOM information, and iDefine from AD Server, the iDefine-config file is also obtained and the file that is to be entered in SCS Manager and the builders is generated.

In the conversion process, you can perform the column check related to the FieldMate Validator or check the items added to the current setting information.

Column check related to the FieldMate Validator

You can check the details of the columns related to the FieldMate Validator of the safety I/O list. When the FieldMate Validation Status and Overwrite Status turn to the following, warning appears.

FieldMate Validation Status is Assigned, or Overwrite Status is Updated

The warning shows the channel in question. The user can verify the details and proceed with the conversion.

Checking added items in the Dictionary view

You can check the current setting information. If the user has defined the same variable name as the additional item, it will result in error. The following message appears and the check is terminated.

Dictionary View: Same variable name exists. (Variable name: xxxx)

Import

You can import the converted file to SCS Manager and the builder.

The contents that were defined in AD Organizer and iDefine are reflected in SCS Manager and the builders. During the import process, the operation history and changed files are not saved.

D4.2 Build process of the SCS project

The SCS project build process obtains the safety I/O list, safety communication I/O list, IOM information, and the iDefine-config file and then runs a build.

The iDefine-config file is obtained when engineering is performed with iDefine. If a reflection is required, you need to run the build after running the reflection.

If there is nothing in the modified list of Generation Manager, you cannot run the build.

After the build succeeds, you cannot run the reflection process and the build again.

■ Difference between the reflection process and the SCS project build process

The difference between the reflection process and the SCS project build process is that the reflection process does not run the SCS project build.

Even if the IOM definition or the assignment is not completed in AD Organizer, you can create the Program Organization Unit (POU). The reason for this is because it is possible to proceed with the creation of the application logic by using the I/O variables of the safety I/O list and safety communication I/O list.

The I/O variables are reflected onto Dictionary View when the reflection process is performed.

SEE ALSO For more information about items that should be configured in the safety I/O list and safety communication I/O list to run the reflection process, refer to:

"■ Handling of the safety I/O list and safety communication I/O list" on page C2-3

■ Build in Generation Manager and SCS Manager

Both the Generation Manager build and SCS Manager build create a database for SCS, but they have the following differences:

If the build succeeds in Generation Manager, the corresponding safety I/O list, safety communication I/O list, and IOM information of AD Organizer are reflected onto the SCS database via SCS Manager. When the safety I/O list, safety communication list, and IOM information are edited by using AD Organizer, the modifications are not imported into the SCS database. Therefore, it is necessary to perform the build with Generation Manager.

On the other hand, when performing a build by using SCS Manager, the status of the safety I/O list, safety communication I/O list, and IOM information of AD Organizer is not taken into account. When downloading to the SCS, the download cannot be done if the safety I/O list, safety communication I/O list, and IOM information of AD Organizer have not been reflected onto the SCS database. You can run the analyzer and launch the SCS simulator.

Therefore, when the safety I/O list, safety communication I/O list, and IOM information are edited, it is necessary to run the build successfully once in Generation Manager.

D4.3 Generation Manager window configuration

Generation Manager screen is shown in the following figure.

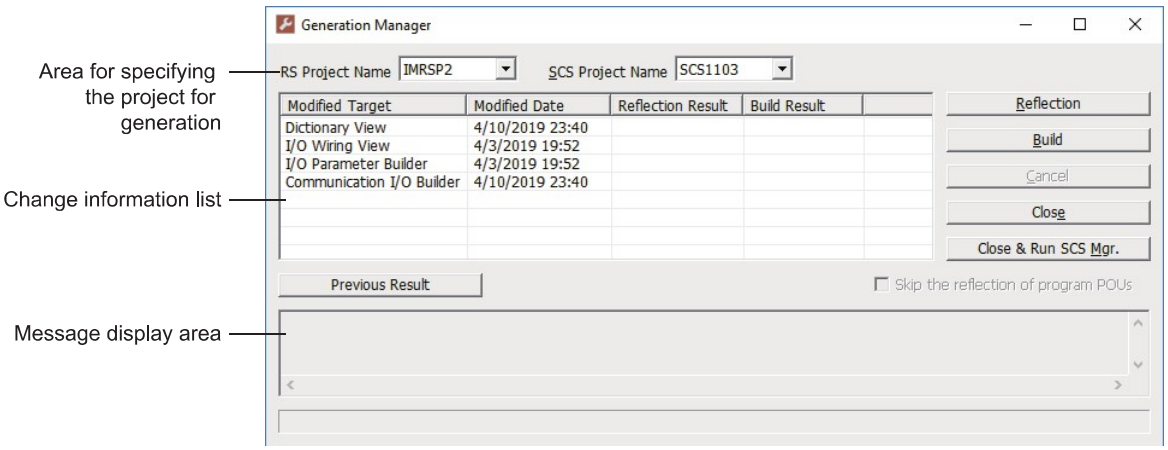

Figure D4.3-1 Generation Manager window configuration

RS project

The target RS project can be selected from the drop-down list box. You can select the RS project that is registered in the AD project.

SCS project

The SCS project that is defined in the RS project can be selected from the drop-down list. The SCS project that is displayed in the list box is the SCS project that is created by using the safety I/O list or safety communication I/O list of AD Organizer from the SCS project properties. The list is displayed in descending order sequence of the domain number and station number. If the RS project is switched in the drop-down list of the RS project, the station at the topmost position in the list will be in the selected state.

Change information list

Only the information related to the SCS project that is selected from the drop-down list box of the SCS project is displayed in the change Information list.

Soon after Generation Manager is started up, the RS project and the SCS project that were selected in the System Structure Navigator during start-up will be in selection status.

The details that are displayed in the change information list is shown in the following table.

Table D4.3-1 Column specification of the change information list

Item name	Description
Modified Target	Displays the name of the build which needs to be changed. When changes need to be made, the builders are shown in the order of Dictionary View, I/O Wiring View, I/O Parameter Builder, Communication I/O Builder, Dictionary View (iDefine), Tag Name Builder, and POU.
Modified Date	The date and time of file update are displayed.
Reflection Result	The results of reflection are displayed. • Succeed: Successful • Fail: Failure
Build Result	The results of the build are displayed. • Succeed: Successful • Fail: Failure

Previous result

The progress status message of the last RS generation is displayed.

Skipping reflection of a program POU

This option is used when the engineering is performed by using iDefine. This option is applicable to SCS projects that use subsystem communication or safety subsystem communication, and you can use the option as necessary when you change the POU included in an SCS for which downloading is already performed.

When the reflection process is performed after loading the iDefine-config file with AD Organizer, changes made to the POUs, variables, FB instances, and tag name information are all reflected together onto the SCS project.

For example, if any changes are made to a user-defined FB that uses a subsystem communication FB, you may want to download only the changed user-defined FB and the changes in the relevant subsystem communication to the SCS first and check the operation of the FB by using the program POU that is already downloaded.

In this case, when the reflection process is performed upon selecting this check box, changes will be reflected onto the SCS project except for the changes in the program POU and tag names in the iDefine-config file. However, even if user-defined FBs or user-defined FUs are deleted in iDefine, they will not be deleted from the SCS project. This is because, if such FBs or FUs are deleted from the SCS project, a build error will result when the FBs or FUs are used in the program POU that is already downloaded.

After testing of user-defined FBs that use a subsystem communication FB and other subsystem communication related functions is finished, clear the check box and run the reflection and build process again. By doing so, you can reflect all changes that were made with iDefine onto the SCS project.

The following table shows the changes of the status icon for the iDefine Configuration folder shown in System Structure Navigator after selecting the check box or clearing it and performing the build process:

Table D4.3-2 Status icon of the iDefine Configuration folder after the build process

Check box	Status icon after the build process
Selected	The work status is retained even if the build is successful. The work status icon remains shown next to the iDefine Configuration folder of System Structure Navigator. The user can continue to perform the reflection process.
Cleared	The work status icon next to the iDefine Configuration folder of System Structure Navigator disappears when the build process is successful.

Message display area

The message display area displays the execution result of RS generation.

Reflection button

When you click the Reflection button, conversion is run and the converted file is imported to SCS Manager and the builders.

While performing the conversion, the safety I/O list, safety communication I/O list, and IOM information file are acquired before the file for import is created. When engineering by using iDefine, the iDefine-config file is also required.

When importing, the file that was generated through conversion is imported to SCS Manager and the builders. The progress status appears in the message display area.

When there is nothing in the modified information, you cannot run the reflection process.

The successfully converted safety I/O list, safety communication I/O list, IOM information file, and iDefine-config file are imported to SCS Manager and the builders.

If the reflection process fails, you can run the reflection process once again. Run the process from the conversion stage again. When the reflection process is canceled by using the Cancel button, the result will be the same as the case when reflection fails.

- In the reflection process, the input/output modules are wired to the existing input/output variables. A check is then run to make sure that it is consistent with the IOM definition. Regardless of whether it is an input/output variable, the following values are compared in the iDefine-config file and AD Suite:
  - I/O Tag
  - I/O Type
  - Node
  - Unit
  - Slot
  - IOM Type
  - Terminal

  If the value is different, an error dialog box appears and the reflection process is stopped.
- If a tag name is included in the iDefine-config file and a CENTUM VP integration package or a CI Server integration package is not enabled, a message stating that the tag name definition is not reflected appears in the message display area.

Build button

This button runs the SCS project build process. After the reflection process succeeds, the SCS project build process is executed.

The safety I/O list, safety communication I/O list, and IOM information file, as well as the iDefine-config file when engineering by using iDefine, are all acquired from the AD Server, the reflection is performed when it is required, and then the SCS project build is run.

If there is nothing in the change information, you cannot run the SCS project build process.

Cancel button

This button cancels the reflection process and the SCS project build process. It is enabled only when the reflection process and the SCS project build process are executed. If the cancel button is clicked during the execution of the reflection process and the SCS project build process, the reflection process and the SCS project build process will be terminated.

When the cancel button is clicked, [Fail] is displayed in the [Reflection Result] or [Build Result] of the change information.

Once the import to SCS Manager and the build are executed, the cancel button will be disabled.

Close & Run SCS Mgr. button

After RS Generation Manager is closed, SCS Manager automatically starts for the corresponding SCS.

Process when the RS project and SCS project were switched in the RS Generation Manager

When the RS project and SCS project are switched in the Generation Manager dialog box, the screen is refreshed. The safety I/O list, safety communication I/O list, and IOM information file, and the iDefine-config file as well when engineering by using iDefine, of the SCS project that was newly selected are acquired from the AD Server, and the change information list shows which builder requires modifications.

D4.4 Operating procedure of RS generation

The RS generation flow is shown in the following figure.

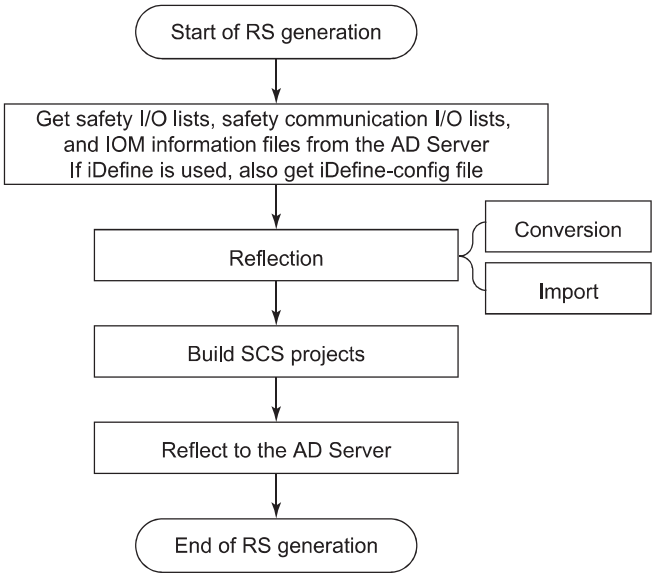

Figure D4.4-1 RS generation process

Starting Generation Manager

1. In the System Structure Navigator of AD Organizer, select SCS.
2. Perform either of the following operations:
   - Right-click and select [RS Generation Manager] from the context menu.
   - Form the sub menu of the System Structure Navigator, select [ProSafe-RS] > [RS Generation Manager].

   Generation Manager starts, and the builder that requires modifications is displayed in the change Information list.

Executing the reflection process

1. You need to select the target RS project and SCS project for RS generation.
2. Check the change information, and click the [Reflection] button.
   If the Access Control and Operation History Management Package is enabled, the Engineer Authentication dialog appears once the import starts.

   If the security of the SCS project is set, the Password Input dialog box appears for the project.
3. Enter the required fields in the Engineer Authentication dialog box and the Password Input dialog box of the SCS project. If the Engineer Authentication and the Password Input dialog boxes do not appear, no action is required.
   The conversion is performed, and the safety I/O list, safety communication I/O list, and IOM information are imported to the AD Server.

   If the reflection process succeeds, Succeed is displayed in Reflection Result.

   If the reflection process fails, Fail is displayed in Reflection Result.

TIP

When the reflection process is performed, you can only use the [Cancel] button.

Reflecting the POU that was defined by using iDefine

When running the reflection process, the POU that was defined by using iDefine is reflected in SCS Manager. The run sequence of the POUs that were defined by using iDefine and SCS Manager is sorted in the Link Architecture View of SCS Manager. POUs that were defined in SCS Manager are not reflected in iDefine. In iDefine, only the run sequence of the POUs that were defined in iDefine is shown.

This section describes the rules for reflecting POUs in SCS Manager after running the reflection process after adding, switching, or deleting POUs in iDefine.

- When POU was added by using iDefine
  POUs that were defined in iDefine and the following POUs that were defined in SCS Manager are treated as a series of the same run sequence; POUs that were added by using iDefine are added below that.

  Example:

  The following example shows how A1, UD1, and UD2 are treated as a series of the same run sequence and A2 is added below that.

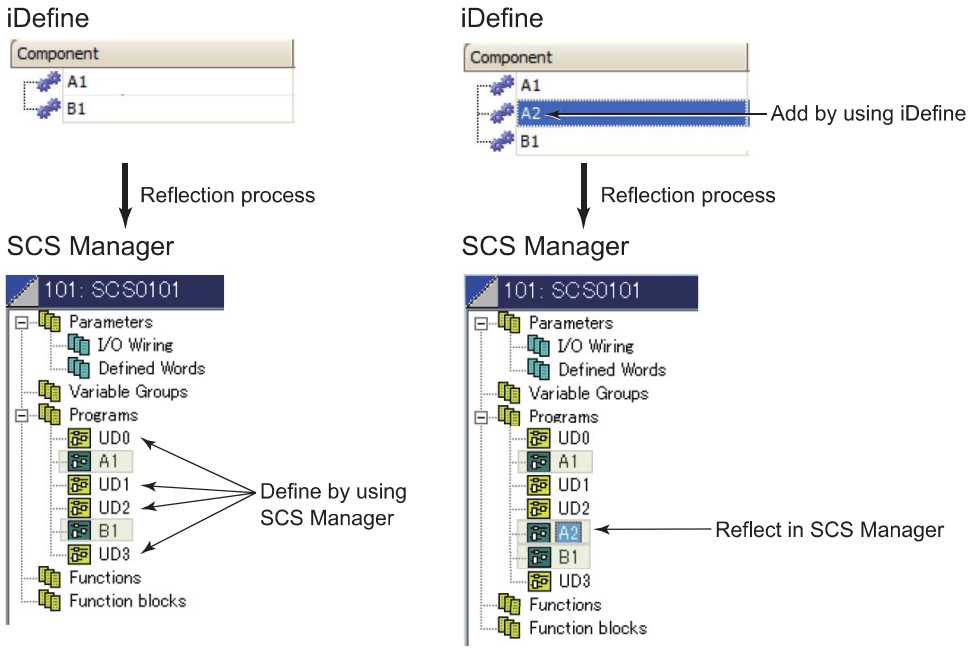

Figure D4.4-2 Reflecting POUs that were added by using iDefine in SCS Manager

- When the POU sequence was changed by using iDefine
  POUs that have had their sequence changed in iDefine and the following POUs that were defined in SCS Manager are treated as a series of the same run sequence, and their sequence in SCS Manager is also changed.

  Example:

  The following example shows how A1, UD1, and UD2, and B1 and UD3 are treated as a series of the same run sequence and how their run sequence is changed.

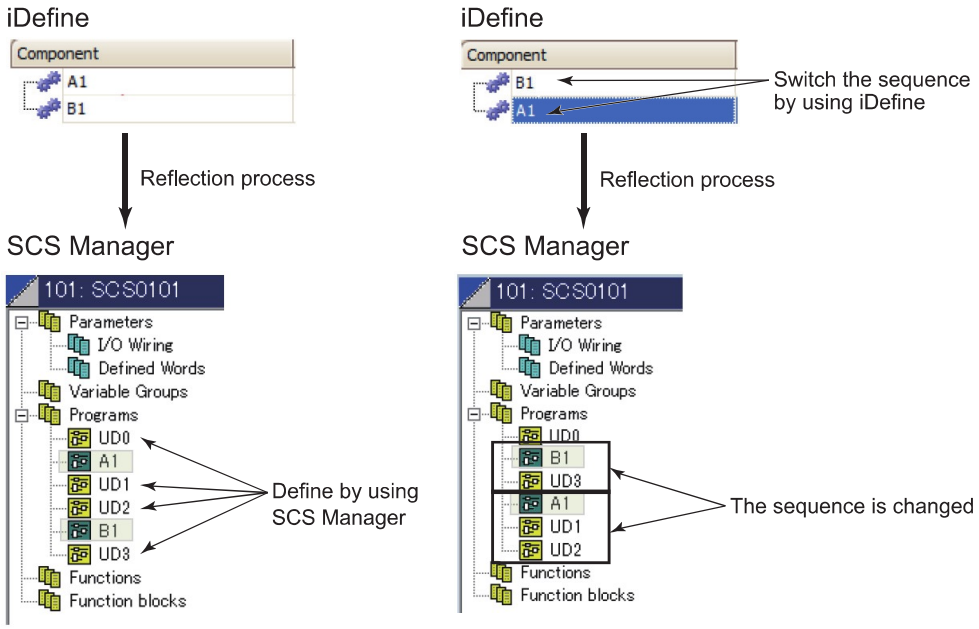

Figure D4.4-3 Reflecting POUs that have had their sequence changed by using iDefine in SCS Manager

- When POU was deleted by using iDefine
  POUs that were deleted by using iDefine are deleted in SCS Manager.

TIP

POUs that were imported from iDefine become read-only in SCS Manager and are displayed with a green icon.

Reflecting the ANN and ANN_FUP tag names that were defined by using iDefine

When running the reflection process, configurations related to the tag names corresponding to the ANN and ANN_FUP instances that were configured by using iDefine are reflected in the Tag Name Builder. Once the instance name has been reflected, it is reflected in the same Element Name in the Tag Name Builder for as long as it exists. New instances that were added by using iDefine are reflected in the unused Element Names in ascending order.

Running the SCS project build process

1. Click the [Build] button in Generation Manager.
   The safety I/O list, safety communication I/O list, and IOM information, as well as the iDefine-config file when engineering by using iDefine, are all acquired from the AD Server, the reflection is performed when it is required, and then the SCS project build process is run.

   The results of the SCS project build process is displayed in the message display area.

   - If the SCS project build process succeeds, Succeed is displayed in Build Result of the change information list. The safety I/O list, safety communication I/O list, IOM information file, and iDefine-config file for which the build is successful are reflected onto the AD Server. You cannot run the reflection process and the build again.
   - If the SCS project build process fails, Fail is displayed in Build Result of the change list. Even if the build fails, the safety I/O list, safety communication I/O list, IOM information, and iDefine-config file are reflected onto SCS Manager as long as the reflection process is successful.

D4.5 Error messages in Generation Manager

This section describes the error messages in Generation Manager.

Error during startup

An error message appears when a communication error occurs during startup. Generation Manager will not start up.

Error during check-out

If the check-out of the safety I/O list, safety communication I/O list, and IOM information file from the AD Server fails when the conversion begins, the name of the file that failed check-out is shown in the message display area.

When a communication error occurs during check-out, the following message is displayed in the message display area.

[Cannot connect to the server.]

Error during unlock

An error message is displayed if a communication error occurs when the reflection process or SCS project build process fails and the check-out is canceled. To release the lock, restart Generation Manager after connecting to the server.

Error during check-in

An error message is displayed if a communication error occurs during check-in to the AD Server after the reflection process and SCS project build process have succeeded. To perform a check-in, restart Generation Manager after connecting to the server.

Error when there is no conversion object

If the reflection button is clicked even though there is nothing in the change information list, the following messages are displayed.

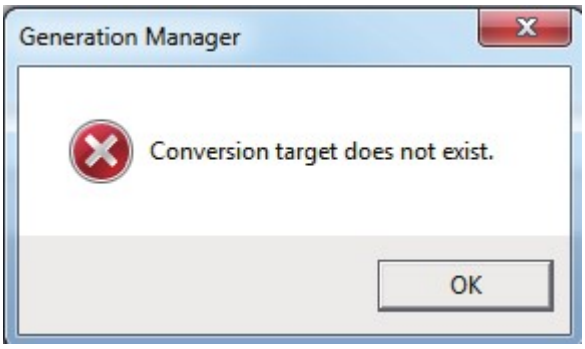

Figure D4.5-1 Error during conversion

After the build has succeeded, this error is displayed when the reflection is performed once again.

Engineer authentication error

When the User Authentication screen of the Access Control and Operation History Management Package appears, and if the engineer group associated with the engineer does not have the required access rights for Dictionary View, I/O Wiring View, I/O Parameter Builder and the

build, the following message appears in the message display area and the reflection process results in an error.

[ERROR: Don't have access right for the operation.]

SCS project security error

If three failed password entry are made for the project in the SCS project security, the following message is displayed in the message display area. Then, the reflection will result in error.

[ERROR: Cannot open the project.]

Error during the reflection process and the SCS project build process

If SCS Manager is started during the reflection process and SCS project build, the following error message is displayed and the processing is terminated.

SCS Manager is being executed.

D4.6 Engineering after changing the safety I/O list and safety communication I/O list

The user can proceed with engineering by using the safety I/O list or safety communication I/O list before the I/O information is fixed. Once the information is fixed, the changes can be reflected in the engineering data by loading the updated safety I/O list or safety communication I/O list at a later stage.

If the safety I/O list is modified, you need to load the safety I/O list into the Safety I/O Editor, check the differences, and reflect them to the database. Once the safety I/O list is imported, you need to use the IOM Definition Editor to define the IOM.

If the safety communication I/O list is modified, you need to load the safety communication I/O list into Safety Communication I/O Editor, check the differences, and reflect them onto the database. Once the safety communication I/O list is imported, you need to use IOM Definition Editor to define the IOM.

When the safety I/O list has been changed, if the engineered results are exported to FieldMate Validator to be tested and are modified, you must import the updated I/O list and reflect the changes onto the SCS project. Once the changes are reflected to the SCS project, you must return to the previous step of engineering and proceed with the task according to the updated details.

D5. Engineering by using iDefine

The following methods are available for engineering by using iDefine:

- Engineering when starting iDefine from AD Organizer
- Engineering when starting iDefine directly

This section describes the engineering steps for each method.

IMPORTANT

When using ProSafe-RS and iDefine, use ProSafe-RS R4.02 to R4.08.

If you want to use SENG to edit engineering data created with iDefine, contact YOKOGAWA.

D5.1 Engineering steps when starting iDefine from AD Organizer

This section describes the engineering steps when starting iDefine from AD Organizer, separately explaining operations in AD Organizer, in iDefine, and in RS Generation Manager.

IMPORTANT

If you are starting iDefine from AD Organizer, install AD Organizer and iDefine on the same computer.

D5.1.1 Operations in AD Organizer

Follow these steps to operate AD Organizer when starting iDefine from AD Organizer:

1. Specify the parameters for input/output and I/O modules.
2. In the System Structure Navigator, click the iDefine for ProSafe-RS icon.
   iDefine starts.

TIP

iDefine starts with the previously loaded iDefine project selected.

IMPORTANT

When performing engineering with starting iDefine from AD Organizer, the iDefine-config file is automatically imported during [Build All] in iDefine. If you want to select an FB with an instance name, do so before running [Build All] in iDefine.

SEE ALSO

For more information about I/O parameter definitions, refer to:

- D1., “Engineering based on the safety I/O list” on page D1-1
- D2., “Engineering based on the safety communication I/O list” on page D2-1

For more information about I/O module parameter definitions, refer to:

D3., “Input/output module configuration definition” on page D3-1

Selecting a FB with an instance name

The instance names of all the FBs that are used in application logics that were created by using iDefine are configured separately. Using this dialog box, you can select whether to assign instance names to the FBs to be reflected in SCS projects for each FB type.

Change the setting to use SCS Manager to assign instance names to any unique FB types that do not have an instance name configured by default or to reduce the number of variables that are registered in the Dictionary View.

Follow these steps to change the settings for FB with an instance name.

1. In System Structure Navigator, right-click with an SCS node selected and select [FB Selection...].
   The FB Selection dialog box appears.

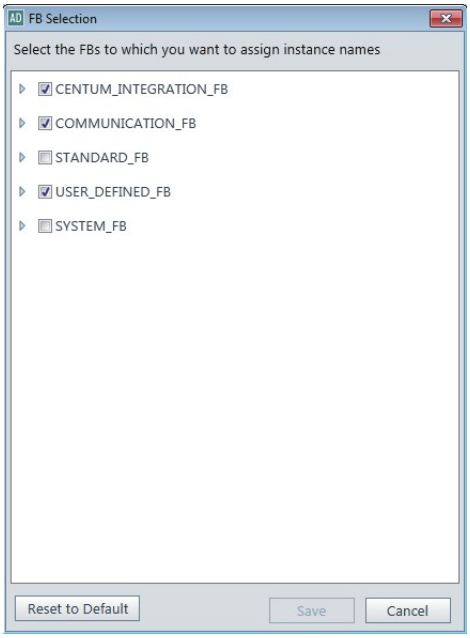

Figure D5.1.1-1 FB Selection dialog box

2. Select the FB with an instance name check box.
   - The function block is categorized; clicking the triangle on the left-hand of a category shows the function blocks contained within that category. You can select all of the check boxes of the function blocks that are contained within a category at the same time by selecting the check box for that category.
   - Clicking [Reset to Default] returns the FB selection status to its initial state.
3. Click [Save].

TIP

The selection of an FB with an instance name can also be done through the Import dialog box.

In the Import dialog box, select the [Show advanced setting] check box and click [Instances].

D5.1.2 Operations in iDefine

Follow these steps to operate iDefine when starting iDefine from AD Organizer:

1. Select an iDefine project and log in.
   iDefine runs in integration mode with AD Suite.

IMPORTANT

iDefine runs in integration mode only if you have started iDefine from AD Organizer. You cannot use the integrated functions of iDefine and AD Organizer if you started iDefine directly.

2. In iDefine Import from AD Suite, select one of the following range for importing I/O and IOM from AD Suite, and import them:
   - Entire AD project
   - RS project
   - SCS project
3. Create an application.
4. In Output Configuration, select the SCS that is the destination for the import of the iDefine-config file, and run [Build] and [Build All].
   Once the iDefine Output Configuration has been built and the iDefine-config file has been imported to AD Organizer successfully, RS Generation Manager starts automatically.

IMPORTANT

- iDefine has an automatic check-in option that runs after creating an iDefine-config file by using [Build All] and importing it to AD Organizer. If you enable this option, you can automatically start RS Generation Manager from iDefine.
- If RS Generation Manager is already running, it cannot be started from iDefine.

SEE ALSO For more information about specific operations in iDefine, refer to:

- iDefine User Guide (PR03076-MAN-970_01)
- iDefine User Guide (Yokogawa Extensions) (PR12002-MAN-980_01)

Creating applications by using iDefine

Follow these steps to create applications by using iDefine:

1. Import the ProSafe-RS I/O file.
   If a value has been entered in the column for iDefine reference, such as Typical, in Safety I/O Editor and Safety Communication I/O Editor, you can view the value for reference purposes in iDefine.
2. Use the following logic editor to create an application template.
   This task can be performed at the same time as the engineering of the I/O list by using AD Organizer, so you can perform this task before importing the ProSafe-RS I/O file.
   - Function Block / Function
   - Typical

   a. In the ProSafe-RS IO Tag Name window, create the parameter pattern for each type to define the tag name.

b. From the variables or function block instances that were defined in Typical, set the created parameter pattern to the one that you wish to assign a tag name.

3. For each I/O Tag, assign the corresponding Typical.
4. Use the following logic editor to create an application logic:
   - Group Typical
   - Cause and Effect module
   - State Analysis module
5. Build by using the Output Configuration and create the variables, tags and an executable program in FBD format.

SEE ALSO For more information about the procedure to import ProSafe-RS I/O files to iDefine, refer to:

10., "IMPORT FROM AD SUITE" in iDefine User Guide (Yokogawa Extensions) (PR12002-MAN-980_01)

D5.1.3 Operations in RS Generation Manager

Follow these steps to operate RS Generation Manager when starting iDefine from AD Organizer:

1. In RS Generation Manager, run the reflection process and the SCS project build process.
2. Click [Close & Run SCS Mgr.].
   RS Generation Manager closes and SCS Manager starts.
3. In SCS Manager, run Safety Analyzer and download to the SCS.
   We recommend that you back up the iDefine project at this step.

SEE ALSO

For more information about RS Generation Manager window configuration, refer to:

D4.3, “Generation Manager window configuration” on page D4-4

For more information about the reflection process and the SCS project build process, refer to:

D4.4, “Operating procedure of RS generation” on page D4-8

For more information about the analysis of SCS projects, refer to:

C5., “Testing with the Safety Analyzers” on page C5-1

For more information about download to the SCS, refer to:

C7., “Offline download to the target SCS” on page C7-1

D5.2 Engineering steps when starting iDefine directly

This section describes the engineering steps when starting iDefine directly.

Engineering is performed in iDefine after creating an iDefine project by using iDefine and using the file exported for iDefine from AD Organizer.

1. Export the ProSafe-RS I/O file from AD Organizer.
2. Import the ProSafe-RS I/O file by using iDefine and create an application. Export the result as an iDefine-config file.
3. Import the iDefine-config file by using AD Organizer. It is recommended that you back up the iDefine project at this step.

SEE ALSO

For more information about the procedures to export files for iDefine from AD Organizer, refer to:

D5.2.1, “Exporting the ProSafe-RS I/O file from AD Organizer” on page D5-9

For more information about the engineering flow when using iDefine, refer to:

C2.2, “Work flow of I/O list engineering with iDefine” on page C2-11

For more information about specific operations in iDefine, refer to:

- iDefine User Guide (PR03076-MAN-970_01)
- iDefine User Guide (Yokogawa Extensions) (PR12002-MAN-980_01)

For more information about tests that are run using iDefine test functions, refer to:

6., “Using iDefine in tests” in Test Function Guide (IM 32P04B30-01EN)

D5.2.1 Exporting the ProSafe-RS I/O file from AD Organizer

If you are using iDefine, export the safety I/O list, safety communication I/O list, and I/O module configurations as a ProSafe-RS I/O file in AD Organizer. The exported file is known as ProSafe-RS I/O file. A ProSafe-RS I/O file is created for each SCS project.

Follow these steps to export the ProSafe-RS I/O file:

If there are any files being edited in Safety I/O Editor, Safety Communication I/O Editor, or IOM Definition Editor, check in the files and export them. Contents that are being edited are not exported.

1. In the System Structure Navigator of AD Organizer, right-click the SCS project to be exported in the System Structure Navigator and select [Safety I/O Editor] or [Safety Communication I/O Editor].

TIP

If you start the Safety I/O Editor in the following ways, you cannot export the ProSafe-RS I/O file.

- Double-clicking the [I/O definition] under the module folder.
- In the Change Set Detail dialog box, right-clicking the file and selecting [Launch Editor] from the context menu.
- Launching the editor in read-only mode.

2. Select [Export to iDefine] from the sub-menu of Safety I/O Editor or Safety Communication I/O Editor.
   The File Selection dialog box appears.
3. Specify the export location, and click [OK].
   The ProSafe-RS I/O file is exported.

TIP

The same data is exported whether you use Safety I/O Editor or Safety Communication I/O Editor. However, different data will be exported depending on what is selected when you start the editor. The relationship between the selection and exported data is as follows:

- When an I/O list is selected
  Safety I/O of all P&ID groups

  Safety communication I/O of all P&ID groups

  Node and I/O module data for all P&ID groups

  Safety I/O parameter profile
- When an RS project is selected
  Safety I/O of all SCSs included in the selected RS project

  Safety communication I/O of all SCSs included in the selected RS project

  Node and I/O module data for all SCSs included in the selected RS project

  Safety I/O parameter profile
- When an SCS project is selected
  Safety I/O of the selected SCS

  Safety communication I/O of the selected SCS

  Node and I/O module data for the selected SCS

  Safety I/O parameter profile

D5.2.2 Operations in iDefine

Follow these steps to create applications by using iDefine:

1. Import the ProSafe-RS I/O file.
2. Use the logic editor to create an application template.
3. For each I/O Tag, assign the corresponding Typical.
4. Use the logic editor to create an application logic.
5. Build by using the Output Configuration and create the variables, tags and an executable program in FBD format.
6. Export the result as an iDefine-config file.

SEE ALSO For more information about creating applications by using iDefine, refer to:

"■ Creating applications by using iDefine" on page D5-5

D5.2.3 Import the iDefine-config file by using AD Organizer

Import the iDefine-config file that was exported from iDefine to AD Organizer. The iDefine-config file contains the POU, I/O Tag, and variables that were defined in iDefine.

Follow these steps to import the iDefine-config file:

1. In the System Structure Navigator of AD Organizer, select the SCS project for which you want to import the file, and select [Import iDefine configuration] from the context menu. The Import dialog box appears.

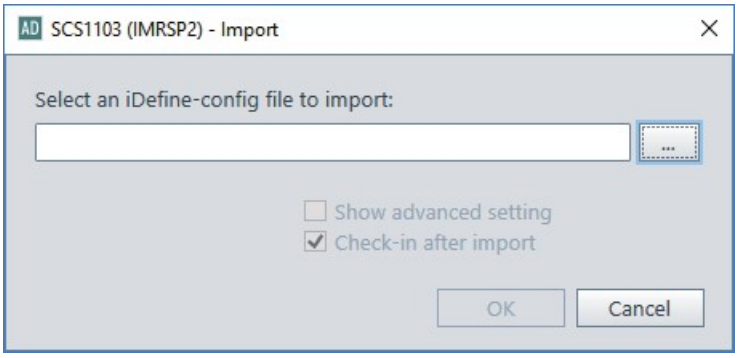

Figure D5.2.3-1 Import dialog box of the iDefine-config file

TIP

If you select an SCS project with a folder that has an exclamation mark, multiple SCS projects, or an SCS project that was created in RS original engineering, you cannot select [Import iDefine configuration].

2. Specify the iDefine-config file that will serve as the import source.
3. Perform either of the following operations:
   - If you do not want to change the settings for FBs with an instance name, skip to step 4.
   - If you want to change the settings for FBs with an instance name, follow the steps described in the next section "■ Selecting a FB with an instance name."
4. In the Import dialog box, click [OK].
   The iDefine-config file is checked out.
5. On the Check-in window, check in the iDefine-config file.
   The iDefine-config file is imported. If you select the [Check-in after import] check box, the iDefine-config file is automatically checked in to AD Server after it has been imported to AD Organizer.
6. Start RS Generation Manager and run the reflection process and the SCS project build process.
7. From AD Organizer, start SCS Manager.
8. In SCS Manager, run Safety Analyzer and download to the SCS.

TIP

Regardless of whether the settings for FBs with an instance name are changed, the FB instance setting file is checked out and checked in together with the iDefine-config file.

SEE ALSO For more information about the reflect, build, and start of RS Generation Manager, refer to:

D4.4, “Operating procedure of RS generation” on page D4-8

For more information about starting SCS Manager, refer to:

A10.2, “SCS Manager” on page A10-3

For more information about the analysis of SCS projects, refer to:

C5., “Testing with the Safety Analyzers” on page C5-1

For more information about download to the SCS, refer to:

C7., “Offline download to the target SCS” on page C7-1

■ Selecting an FB with an instance name

The instance names of all the FBs that are used in application logics that were created by using iDefine are configured separately. Using this dialog box, you can select whether to assign instance names to the FBs to be reflected in SCS projects for each FB type.

Change the setting to use SCS Manager to assign instance names to any unique FB types that do not have an instance name configured by default or to reduce the number of variables that are registered in the Dictionary View.

SEE ALSO For more information about the selection of an FB with an instance name, refer to:

“■ Selecting a FB with an instance name” on page D5-3

D5.3 Precautions when performing engineering by using iDefine

This section describes the terms used in ProSafe-RS and iDefine and the setting items that have any difference in specifications as the precautions for using iDefine in the engineering work.

You must understand these precautions before you start engineering.

IMPORTANT

If iDefine that was started by AD Organizer is operating, a dialog box appears and AD Organizer cannot be ended.

I/O Wiring

The following table compares the I/O Wiring information that is displayed in ProSafe-RS and iDefine.

Table D5.3-1 Comparison of terms between ProSafe-RS and iDefine (I/O Wiring information)

iDefine term	ProSafe-RS term	Description
Ch - Chassis	Node	iDefine identifies if the Node is for N-IO or FIO by adding a prefix. Format: [F/N][Node no.] F: Indicator for FIO, N: Indicator for N-IO
Sl - Slot	Unit	iDefine combines the information for Unit and Slot in the case of N-IO. Format for FIO: [Slot no.] Format for N-IO: [Unit no.][Slot no.]
	Slot	
Pt - Point	Channel or Terminal	Channel in the I/O Parameter Builder, and Terminal in AD Organizer

Variables

The following table compares the variables terms displayed in ProSafe-RS and iDefine.

Table D5.3-2 Comparison of terms between ProSafe-RS and iDefine (Variables)

iDefine term	ProSafe-RS term	Description
Tag	Variable (Global Scope)	Global variables of ProSafe-RS are called "Tag" or "TriTag" in iDefine. In iDefine, Tags are defined in Client IO Table and Typical. The defined Tags are reflected in Dictionary View of ProSafe-RS as variables.
Variable	Variable (Local Scope) Parameter	In ProSafe-RS, variables and parameters are defined by Dictionary View. In iDefine, those are defined by Typical, Function Block, or Structured Text. Local variables and parameters of ProSafe-RS are called “Variable” in iDefine.

Variable types

In iDefine, Tag types are specified in Client IO Table. The Tags will be reflected in Dictionary View as global variables. The following table shows the mapping between Tag types in iDefine and variable types in ProSafe-RS.

Table D5.3-3 Mapping of terms between ProSafe-RS and iDefine (Tag types in iDefine and variable types in ProSafe-RS)

Tag type in iDefine	Variable type in ProSafe-RS	Description
RI	IO_REAL	-
RO	IO_REAL	-
DI	IO_BOOL	-
DO	IO_BOOL	-
IM	DINT	-
DM	BOOL	-
RM	REAL	-
DEVICE	N/A	Variable will not be created in Dictionary View of ProSafe-RS for Tags of this type. This Tag type is used to assign a Typical to a Tag and instantiate the Typical.
IC	COM_DINT	Binding variable for inter-SCS safety communication
RC	COM_REAL	Binding variable for inter-SCS safety communication
DC	COM_BOOL	Binding variable for inter-SCS safety communication

Functions and function blocks

The following table shows the functions and function blocks that have different names in iDefine and ProSafe-RS, or those available only in either of them.

Table D5.3-4 Mapping of functions and function blocks between iDefine and ProSafe-RS

Category	iDefine name	ProSafe-RS name	Description
IEC61131-3 standard functions	ADD	+	Supported parameter data types are different between iDefine and ProSafe-RS. When you perform engineering by using iDefine, use parameters of the data type DINT, REAL, STRING, or TIME, which are supported by ProSafe-RS. If parameters of types other than DINT, REAL, STRING, and TIME are used, a build error will occur.
	DIV	/	-
	GE	>=	-
	GT	>	-
	LE	<=	-
	LT	<	-
	MOVE	1 GAIN	-
	MUL	*	-
	NE	<>	-
	SUB	-	-
TIS function	NUMBITS	-	Exported as user-defined function (ST) NUMBITS8 or NUMBITS16.

Continues on the next page

Table D5.3-4 Mapping of functions and function blocks between iDefine and ProSafe-RS (Table continued)

Category	iDefine name	ProSafe-RS name	Description
StateModule function blocks (*1)	TIS_CALCST	-	Exported as user-defined function block (ST).
	TIS_COND2	-	Exported as user-defined function block (ST).
	TIS_COND3	-	
	TIS_GST	-	Exported as user-defined function block (FBD).
	TIS_SE	-	Exported as user-defined function block (ST).
	TIS_SE_FIRST	-	
	TIS_SE_NT	-	
	TIS_SEP4	-	Exported as user-defined function block (ST). This creates AND_DWORD and OR_DWORD user-defined functions (ST) together.
	TIS_TMR	-	Exported as user-defined function block (ST).
StateModule functions (*2)	TIS_SEP1	-	Exported as user-defined function (ST).
Gas flow rate calculation function blocks (Interference-free)	-	ACCUM	Not supported in iDefine.
	-	AGA_3	
	-	AGA_7	
	-	AGA_R	
	-	ECWR_B	
	-	ECWR_I	
	-	ECWR_R	
Data buffering function blocks (Interference-free)	-	BUF_DIF_B	Not supported in iDefine.
	-	BUF_DIF_I	
	-	BUF_DIF_R	
	-	BUF_TIM_I	
	-	BUF_TIM_R	
	-	BUF_TRIG_B	
	-	BUF_TRIG_I	
	-	BUF_TRIG_R	
DNP3 communication function blocks (Interference-free)	-	DNP3_AI_16	Not supported in iDefine.
	-	DNP3_AI_32	
	-	DNP3_AI_SF	
	-	DNP3_AO_16	
	-	DNP3_AO_32	
	-	DNP3_AO_SF	
	-	DNP3_BI	
	-	DNP3_BO	
	-	DNP3_CT_16	
	-	DNP3_CT_32	

*1: Function blocks that are created when an SA module is converted to FBD
*2: Functions that are created when an SA module is converted to FBD

Differences of terminology during test operations

The terminology during test operations vary between iDefine and ProSafe-RS. The following table shows the correspondence between the varying terminologies.

Table D5.3-5 Correspondence chart for test operation terminology of iDefine and ProSafe-RS

iDefine Terminology	ProSafe-RS Terminology
Disable	Lock
Enable	Unlock
Set	Write
Single Step	One Cycle
Start Debug	Start Debug Mode
Stop Debug	Stop Debug Mode
Start Target	Simulation
Stop Simulator	Stop Simulation Mode
Cycle Scan Time	Cycle Timing

Notes on the reflection process for the iDefine-Config file

When the reflection process is performed after loading the iDefine-config file including subsystem communication FB or safety subsystem communication FB with AD Organizer, the POU and FB are all downloaded together onto the SCS project. In order to verify the subsystem communication FB or safety subsystem communication FB alone before downloading the application, use the function for skipping reflection of the program POU onto the SCS project.

SEE ALSO For more information about how to skip reflection of a program POU onto an SCS project, refer to:

"■ Skipping reflection of a program POU" on page D4-5

Cautionary notes on the use of the POWE/LOGE function

When using the POWE/LOGE function with the iDefine-config file that the reflection process is performed, POWE/LOGE is handled as either a safety function or an interference-free function, depending on the revision of the new SCS project created by SENG. The logic behavior of POWE/LOGE remains unchanged.

The following table describes the revision of the new SCS project created by SENG and the handling of POWE/LOGE.

Table D5.3-6 Revision of new SCS project created by SENG and handling of POWE/LOGE

Revision of new SCS project created by SENG	Handling of POWE/LOGE
Earlier than R4.07	Interference-free function
R4.07 or later	Safety function

E. Changing application

This section describes the procedure for online change of applications, procedure of import/ export, and the procedure to reuse SCS project database.

E1. Online change of applications

This chapter describes the procedure for online change of applications.

E1.1 Online change download

Online change download changes a part of an application without interrupting SCS functions. In SCS, the data stored in main memory of the CPU module is updated and changes are stored in flash memory of the CPU module as well. When performing online change download of I/O definitions, changes are also reflected in the non-volatile memory of the input/output modules. Data downloaded to an SCS is also saved in the master database on the SENG.

TIP

The SCS operating mode will not be changed when online-change downloading is performed.

Items for which online change download is allowed

SCS engineering tasks may include items for which online change download is allowed and items for which offline download is necessary.

IMPORTANT

- If the variable cannot be added by online change download depending on the state of free memory space, Clean Project and Offline Download are required. However, if you review and delete unused I/O modules and variables, you may be able to add new variables via online change download.
- Builders allow generating parts of database where online change download is not allowed.
  If you make changes exceeding the range where online change is possible, you will be notified that the downloading is impossible after performing the download operation.

  If it is notified that online change download is not possible, close SCS Manager once and use Master Database Restoring Function to revert the modified data to the same status as the data in the SCS.
- When engineering by using iDefine, you cannot check whether you can make changes online in iDefine. As such, make sure you confirm which items to change before changing anything. You will not be able to perform changes online after the changes have been reflected in SCS Manager; if you use the Master Database Restoring Function, the iDefine project database must also be restored to its previous state. As such, it is recommended that you back up the iDefine project database before making changes in iDefine.
- When modifying the logic, the related output channels should be locked-out on the I/O Lock window. However, locked channels cannot output values in response to demand. Analyze the impact of locking channels on the system in advance and implement the necessary measures before locking channels.
- When performing online changes for POUs, make sure to consider the items related to "Miscellaneous limitations" of the "Online changes" description in the "Debug" section of the "Workbench" chapter in the Workbench User's Guide.

Procedure for online change download

This section describes procedures from building application logic to storing SCS project after an online change download.

What to do before online change download

Build the application logic and analyze it by using Integrity Analyzer and Cross Reference Analyzer.

TIP

The items that may require retesting but not detected by Cross Reference Analyzer must be checked by the user.

IMPORTANT

Call up the SCS Information dialog box and confirm that the number of logical I/O points in use does not exceed the number of granted I/O licenses.

Use the SCS security level operation function to set the SCS security level to Level 1.

After that, open the I/O Lock window and lock the input and output modules to be affected by online change downloading.

Start the online change download

1. From the [Debug] menu in SCS Manager, select [Online Change: Download]. Alternatively, click the [Online change download] button on the toolbar.
   The Online Change Download Confirmation dialog box appears.

TIP

- If Integrity Analyzer or Cross Reference Analyzer has already been launched when you start online download, a message prompting to close the analyzer is notified and the download ends with an error.
- If the SCS security level is set to Level 2 when the online change download starts, a message prompting you to change the security level appears and the program aborts. Set the security level to Level 1 and start an online change download.
- If the I/O Lock window or Inter-SCS Communication Lock window is left open when you start online change download, an error message appears and the download processing stops.

2. Click [OK].
   A dialog box prompting to confirm the version control appears.

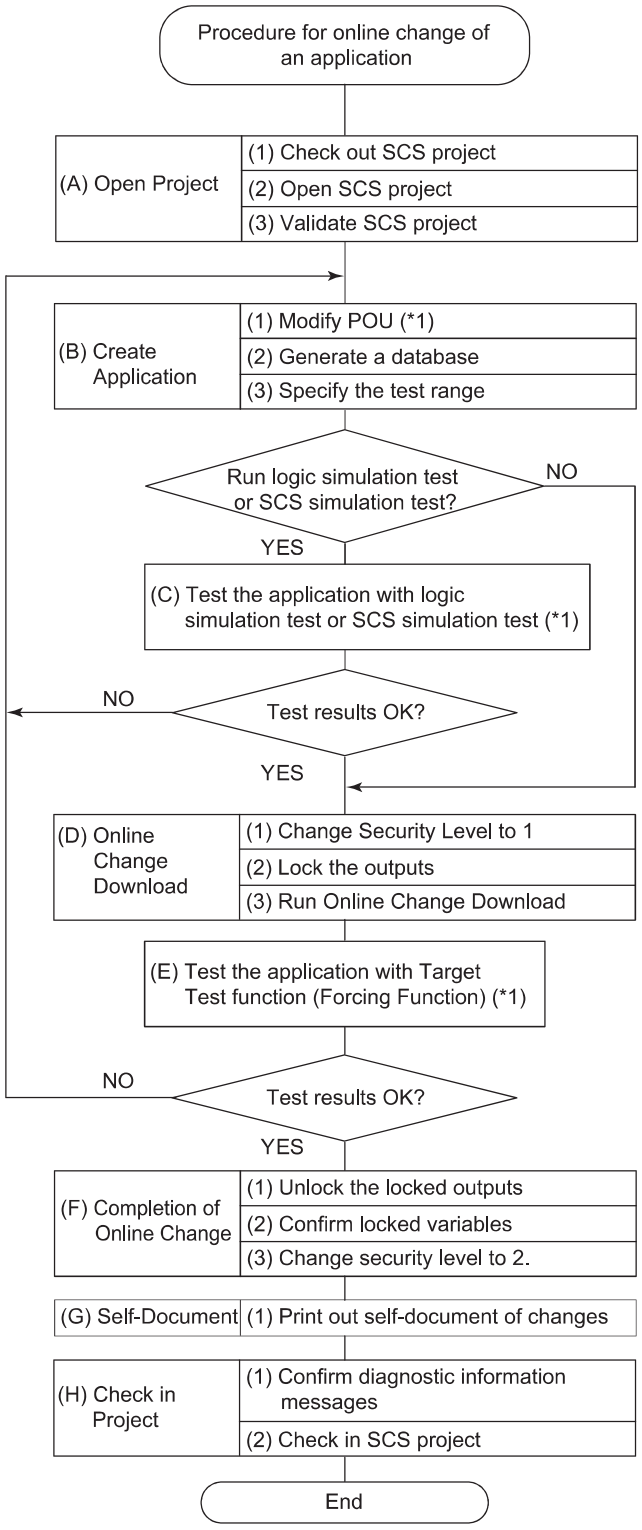
When the Scan period of the application logic is changed

If the scan period of the application logic has been changed, a confirmation dialog box appears when you start online change download. If there are any changes that take long time in downloading, another confirmation dialog box appears.

Check the application logic and end online change download

Using SCS Manager, change the SCS mode to Target test mode and test the changes you made. After the test, unlock the input and output modules which were previously locked using the I/O Lock window. And perform the output enable operation.
From the Set SCS Security Level dialog box, change the security level to Level 2. After that, save the SCS project using the Version Control Tool.

E1.2 Entire procedure of online change of application



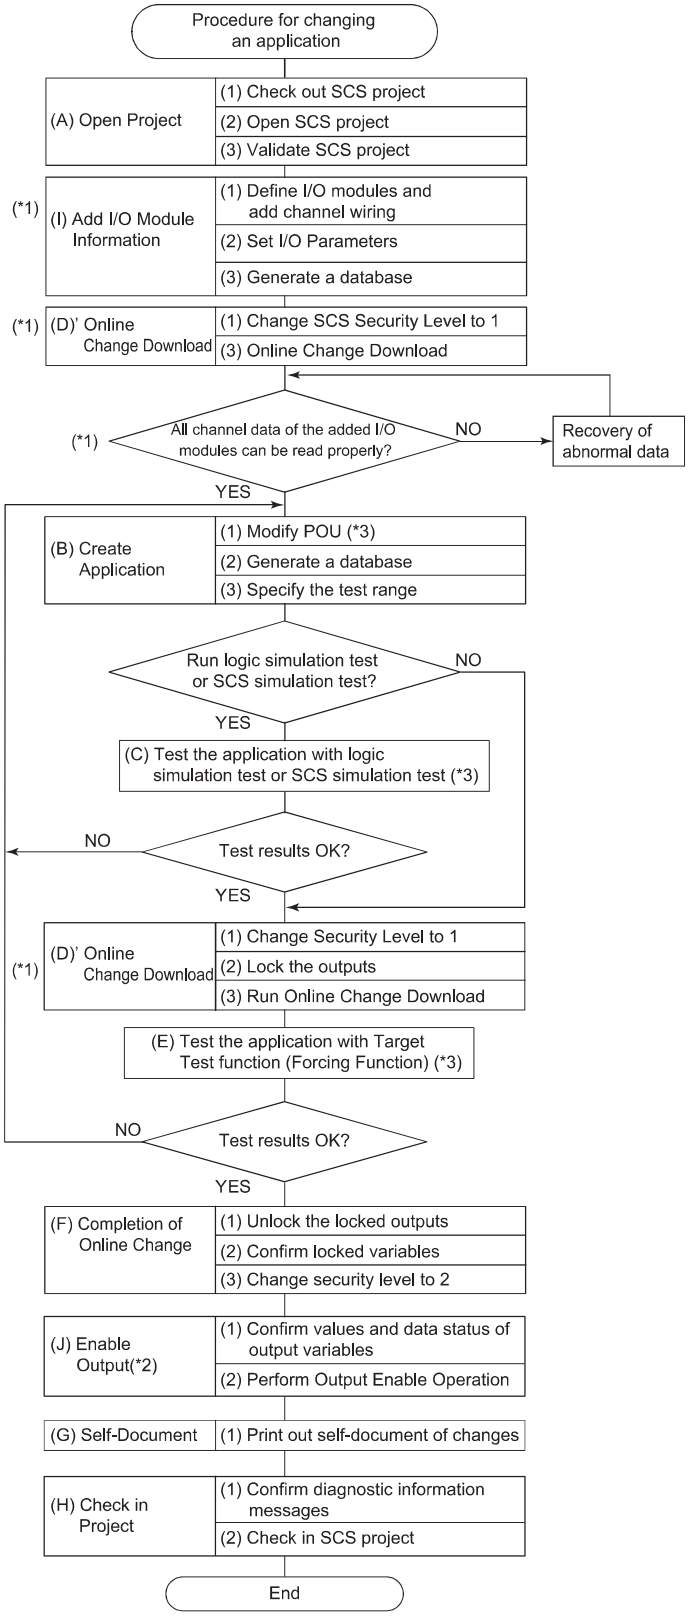
This section describes a procedure for online change of an application.

Procedure for online change of an application

Before performing an online change of an application, you need to analyze possible effects caused by the change carefully and take the appropriate measures. This section describes procedures for online change of application for both the following cases: online change of applications with addition or change of I/O modules, and online change of applications without addition or change of I/O modules.

Online change of applications with addition or change of I/O modules

The following describes the procedure for online change of applications without addition or change I/O modules.



*1: You can use iDefine functions when you use I/O list engineering with iDefine.

Figure E1.2-1 Procedure for online change of an application

Online change of applications with addition or change of I/O modules

The following describes the procedure for online change of applications with addition or change I/O modules.
Before performing the following procedure, you need to install the I/O modules in the nodes and complete the required hardware setups such as field wiring and connection of power sup-

ply. Then, by using the following procedure, you need to make sure that all data of the added channels are normal, and generate the application or implement the changes.

*1: These steps are different from the procedure for online change without adding input/output modules.
*2: This is required only when you add output channels or output modules.
*3: You can use iDefine functions when you use I/O list engineering with iDefine.

Figure E1.2-2 Procedure for online change of an application (with addition and change of I/O modules)

SEE ALSO For more information about changing hardware, refer to:

E., “Maintaining the SCS” in Hardware User's Guide (IM 32P06C10-01EN)

(A) Opening the project

Table E1.2-1 Procedure for opening a project

Item	Description
(1) Check out SCS project	• Check out the existing SCS project with the Version Control Tool.
(2) Open SCS project	• Start SCS Manager from AD Organizer. • Open the SCS project. • Enter the password for the SCS project.
(3) Validate SCS project	• Run the Database Validity Check Tool and check that the CRC codes and generation times of the databases are consistent between the SCS and SCS project. • Repair a database if there is a discrepancy in the database.

SEE ALSO For more information about precautions for handling an SCS project engineered by I/O list engineering that was checked in with Version Control Tool of a revision earlier than R4.03.10, refer to:

“■ Precautions for handling an SCS project that was checked in with Version Control Tool of a revision earlier than R4.03.10” on page C3-2

(B) Creating an application

Table E1.2-2 Procedure for creating an application

Items	Description
(1) Modify POU	If you are not using iDefine: • Open the POU that you want to change. • Edit POU. • Save POU. • Print POU. • Confirm that the logic entered in Multi-Language Editor is the same as the logic printed by using the self-document function. If you are using iDefine: • Export the ProSafe-RS I/O file from AD Organizer and import it in iDefine. • Change the POU, variables and tag-related definitions by using iDefine. • Export the iDefine-config file from iDefine and import it in AD Organizer. • Run Reflection by using RS Generation Manager. Confirm that the run sequence for FB and FU is correct.
(2) Generate database	• Perform Build. • Analyze and confirm that the safety applications such as FU/FB are correct in terms of safety by using the Integrity Analyzer. • Call up the SCS Information dialog box and confirm that the number of logical I/O points in use does not exceed the number of granted I/O licenses.

Continues on the next page

Table E1.2-2 Procedure for creating an application (Table continued)

Items	Description
(3) Specify the range of testing	• Check the modified POU and the affected POU with the Cross Reference Analyzer and then authorize them. For the POU detected by the Cross Reference Analyzer, check the contents of the change with the Project Comparing Tool, determine whether the change affects the behavior of the logic, and add to the test target if any effects are expected. • Use the Project Comparing Tool to confirm that the following settings (for which Cross Reference Analyzer cannot confirm the existence of changes, which are critical in terms of safety, and through which online change download is made possible) are not unintentionally changed: Item in Resource Properties window: • [Cycle Timing] Items in SCS Constants Builder: • [Extend Scan Period Automatically] (*1) • [Behavior at Abnormal Calculation] (*1) • [Automatic IOM Download] (*1) • [Locking of Internal Variables] (*1) (for SCSP3/SCSL2/SCSP2) • [Device Power-Off Period] (for SCSP3/SCSL2/SCSP2/SCSP1/SCSU1) • [Device Startup Waiting Period] (*1)(for SCSP3/SCSL2/SCSP2/SCSP1/SCSU1) • [Skip Password Dialog Box for Manual Operation FB] (*1)(for SCSP3/SCSL2/SCSP2/SCSP1) Items in I/O Parameter Builder • [Extends Node Bus] (*1) • [Extends To (km)] (*1)

*1: The corresponding item may not exist or the configurable value may be different depending on the software release number of the system or SCS type. Such items may therefore be picked up as discrepancies by the Project Comparing Tool.

(C) Testing applications with logic simulation test functions and SCS simulation test functions

Test the user application with the logic simulation test functions or SCS simulation test functions.

SEE ALSO For more information about details of logic simulation test and SCS simulation test, refer to:

C6., “Simulation tests” on page C6-1

(D) (D’) Online change download

Table E1.2-3 Procedure for online change download

Items	Description
(1) Change SCS Security Level	• Start the SCS Maintenance Support Tool which monitors the SCS from the SCS Manager. • Set the security level to 1. Entering a password is required. • Confirm that the SCS Security Level is 1 on the SCS State Management window of SCS Maintenance Support Tool. • Confirm the diagnostic information message indicating the security level at 1 with the SCS Maintenance Support Tool.
(2) Fix the output	• Locks all the channels of the output modules connected to the modified POU or to be modified POU. • Use the SCS Maintenance Support Tool to confirm that a diagnostic information message is output, indicating that the abovementioned modules have been locked.

Continues on the next page

Table E1.2-3 Procedure for online change download (Table continued)

Items	Description
(3) Online Change Download	• Perform online change download. • Establish a communication. Confirm that no communication error occurs. • Confirm that the diagnostic information message is not issued, which is caused by a write error to the flash memory of SCS. If it is issued, perform Offline download. • Use the Database Validity Tool to confirm that CRC and generation time of four kinds of databases for SCS project databases are correct. Confirm that CRC of four kinds of databases and generation time are correct. • Repair a database if there is a discrepancy in the database. • Confirm that the total number of POU notified in the diagnostic information message about the change of resources (No.4172) is identical to the total number of POU shown in the Database Validity Tool. • If downloaded to Output module, validate the output after the download.

CAUTION

I/O Lock is a function to prevent unnecessary shutdowns in the following conditions:

- System malfunction caused by unintended errors in application programs
- Temporary halt of the I/O module when the I/O module settings are changed

If you lock the output, you can conduct target tests to check the behavior of a modified logic. However, if you are sure in advance that the above mentioned system malfunction or temporary halt does not occur, or that the occurrence causes no problem, you do not need to lock I/O. Furthermore, locked channels cannot output values in response to demand. Analyze the impact of locking channels on the system in advance and implement the necessary measures before locking channels.

The explanations in Instruction Manuals (IM) for ProSafe-RS rest on the premise that you use the I/O Lock function.

SEE ALSO For more information about repairing a database, refer to:

"■ Repair database" in F3., "Database Validity Check Tool" in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about precautions for online change, refer to:

E1.5, "Precautions for online change" on page E1-20

For more information about precautions related to locks, refer to:

2.6, "Forcing" in Safety Manual (IM 32P01S10-01EN)

(E) Target test functions

Perform the output enable operation and test the user application on the target SCS.

SEE ALSO For more information about details of target test, refer to:

C9., "Target tests" on page C9-1

(F) Completion of online change

Table E1.2-4 Procedure for completion of online change

Items	Description
(1) Unlock the locked outputs	• Confirm that, for the digital output modules concerned, the values and statuses of logical data agree with those of physical data. • Unlock the output modules concerned. • Confirm that the diagnostic information message which indicates the output modules concerned have been unlocked is output with the SCS Maintenance Support Tool. • Disable the bypass to the actuator.
(2) Confirm locked variables	• Confirm the number of locked variables is 0 with the SCS Maintenance Support Tool. • Confirm that no diagnostic information message is issued except for one you confirmed, with the SCS Maintenance Support Tool.
(3) Change the security level to 2	• Set the security level to 2. • Confirm that the security level is 2 in the SCS State Management window of the SCS Maintenance Support Tool. • Confirm the diagnostic information message which indicates that the security level went back to 2 with the SCS Maintenance Support Tool.

(G) Self-document

Table E1.2-5 Procedure for Self-document

Items	Description
(1) Print out modified parts of the project using self-document	• In preparation for the desk check performed at application software changes in the future, print out the latest SCS project database as self-documents.

(H) Check in project

Table E1.2-6 Procedure for checking in a project

Items	Description
(1) Confirm the diagnostic information message	• Confirm that diagnostic information message other than one you confirmed is not issued with the SCS Maintenance Support Tool.
(2) Check in the SCS project	• Close the SCS Manager. • Check in the SCS project.

(I) Adding I/O module information

Table E1.2-7 Procedure for adding I/O module information

Items	Description
(1) Define I/O modules and add channel assignment	For I/O list engineering • Obtain the latest safety I/O list and import it by using Safety I/O Editor. Alternatively, obtain the latest safety communication I/O list and import it by using Safety Communication I/O Editor. • Use Safety I/O Editor, Safety Communication I/O Editor, and IOM Definition Editor to define I/O modules and I/O parameters. • If this affects the applications created by using iDefine, export the ProSafe-RS I/O file from AD Organizer and import it in iDefine to repair the iDefine application. For RS original engineering • Define I/O variables with the Dictionary. • Add I/O module definitions and define parameters. • Connect I/O variables to channels.

Continues on the next page

Table E1.2-7 Procedure for adding I/O module information (Table continued)

Items	Description
(2) Specification of I/O parameter	For RS original engineering • Define all parameters of nodes, units, modules, and channels.
(3) Generate a database	• For I/O list engineering After changing the application by using iDefine, export the iDefine-config file from iDefine and import it to AD Organizer. Start the Generation Manager from AD Organizer and execute reflection or RS generation process. • For RS original engineering Perform Build. • Analyze and confirm that the safety applications such as FU/FB are correct in terms of safety by using the Integrity Analyzer. • Use the SCS Information dialog to confirm that I/O license is available.

(J) Enabling output

Table E1.2-8 Procedure for enabling output

Items	Description
(1) Confirm values and data status of output variables	• Confirm which output channels are disabled on the SCS State Management window of SCS Maintenance Support Tool. • Start the I/O Lock Window.(This can be performed at security level 2.) • Confirm that values and statuses of logical data and physical data for output variables are correct.
(2) Operate “Enable Output”	• Perform the Output Enable Operation for output modules on the SCS State Management window of SCS Maintenance Support Tool. • Confirm that the diagnostic information message on the Output Enable Operation for output modules is displayed. • Confirm that Output Channels are enabled on the SCS State Management window. • Confirm that the SCS operating mode is "Running" on the SCS State Management window.

SEE ALSO For more information about details of the enable output operation, refer to:

“■ Enable Output operation” on page C8-2

E1.3 List of applicable items for online change

This section describes the items for which you can perform online change download and those which require offline download. If stopping SCS control is not allowed, setting items that require offline download must not be changed.

IMPORTANT

If you change setting items that require offline download, even if you reverse the change, online change download is not allowed. If this happens, use Master Database Restoring tool to recover the database to a state where online change download is allowed. When engineering by using iDefine, you must restore the iDefine project database as well.

SEE ALSO

For more information about online change availability for SCS operating on a SCS system program revision of R2.02 or earlier, refer to:

"■ Possibilities of online change download" on page App.3-5

For more information about operations of the Master Database Restoring function, refer to:

F4., "Master Database Restoring Function" in Engineer's Reference Manual (IM 32P04B10-01EN)

■ Online change of POU information

There are changes that enables you to execute online change download or offline download according to each POU type.

● Changing POU

The following table shows whether POU can be changed online. For an SCS project newly created with SENG R4.09.00 or later or when clean project is executed for an SCS project earlier than R4.09.00, online change download is available when newly creating, deleting, or renaming all program, user-defined FU, and user-defined FB POUs.

Table E1.3-1 Whether or not online change can be used for POU operations

Type of POU	Changing a name	Creating, deleting
Program	Yes	Yes
User-defined FU	Yes	Yes
User-defined FB	Yes	Yes

● Changing POU logic

When you perform a change operation on POU described in the following table, you can perform an online change download to SCS.

Table E1.3-2 Logic change operations that can be changed online on POU

Corrected item	Description
Adding/deleting the standard FU call	-
Adding/deleting the user-defined FU call	Including FU defined in the library. A project that is created with the revision earlier than R3.02.00 will be in the same condition as R3.02.00 when clean project is executed. Therefore, you can perform an online change download.
Changing logic	-

Changing a library

For an SCS project newly created with SENG R4.09.00 or later or when clean project is executed for an SCS project earlier than R4.09.00, online change download is available when adding or deleting a library from SCS project or renaming a library.

Changing program

The following table shows the operations that can perform online change download to SCS for global variables, global instances, local variables, and local instances that are used in Program.

Table E1.3-3 Operations that can be changed online for variables and instances used in program

Corrected item	Description
Adding/deleting a variable	-
Deleting variables and adding variables with the same names as the deleted variables	-
Changing the types of variables	-
Changing attributes of variables	-
Adding/deleting I/O variables	-
Adding/deleting the standard FB instances	-
Adding/deleting the user-defined FB instances	Including FB defined in the library. A project that is created with the revision earlier than R3.02.00 will be in the same condition as R3.02.00 when clean project is executed. Therefore, you can perform online change download.
Deleting FB instances and adding FB instances with the same names as the deleted ones	
Changing the types of FB instances	

Changing user-defined FB

The following table shows the corrections that need offline download to SCS for the parameters of user-defined FB. A warning is displayed at the build operation when performing the correction in the table. An error occurs at online change download operations.

However, if the user-defined FB to be changed meets the following conditions, no warning or error will occur and the online change can be made.

- User-defined FB instances are not defined in Dictionary.
- Instances without name are not used in Program.

Table E1.3-4 Operation of parameters that need offline download in user-defined FB

Modification	Description
Adding/deleting a parameter (*1)	-
Deleting parameters and adding parameters with the same names as the deleted parameters (*1)	-
Changing the types of parameter (*1)	-
Changing the attributes of parameter (*1)	As the attributes of user-defined FB parameters, the following items cannot be changed online. Direction, () (specification of the number of characters for STRING variables: [Not supported]), Dimension
Adding/deleting the standard FB instances (*1)	If you add FB instances without names (not appearing in the Dictionary) in user-defined FB, the FB instances become parameters and thus cannot be changed online.
Adding/deleting the user-defined FB instances (*1)	
Deleting FB instances and adding FB instances with the same names as the deleted ones (*1)	
Changing the types of FB instances (*1)	-

*1: Online change download is available by deleting the user-defined FB and creating a new user-defined FB with the same name. However, in this case, the created user-defined FB instance operates as a new instance that is different from the user-defined FB before deletion, regardless of whether there are differences in parameter definitions. Even if the parameters are the same in the definition, values are not inherited.

The following table shows the corrections that you can execute online change download to SCS for the global variables and the global instances used in user-defined FBs.

TIP

Normally, global variables and global instances are not used in user-defined FBs.

Table E1.3-5 Operations that can be changed online for global variables and global instances used in user-defined FB

Modification	Description
Adding/deleting a variable	-
Deleting variables and adding variables with the same names as the deleted variables	-
Changing the types of variables	-
Changing the attributes of variables	-
Adding/deleting the standard FB instances	-
Adding/deleting the user-defined FB instances	Including FB defined in the library. A project that is created with the revision earlier than R3.02.00 will be in the same condition as R3.02.00 when clean project is executed. Therefore, you can perform online change download. When adding user-defined FU/FB, the added user-defined FU/FB must be tested. When adding pre-validated user-defined FB, testing of the FB itself is not required.
Deleting FB instances and adding FB instances with the same names as the deleted ones	Including FB defined in the library. A project that is created with the revision earlier than R3.02.00 is in the same state as R3.02.00 when clean project is executed. Therefore, it can perform online change download.
Changing the types of FB instances	

Changing user-defined FU

The corrections that you can execute online change download for parameters or local variables in user-defined FU are as follows:

- Adding/deleting
- Deleting variables and adding variables with the same names as the deleted variables
- Changing the types of variables
  However, when the type of output parameter is changed, offline download is required.
- Changing attributes of local variables

SEE ALSO

For more information about the precautions that should be taken when deleting a variable or function block and then adding it again, refer to:

"Declared Variables" in "Variables" in "Online Change" in "Debug" in "Workbench" of "Workbench User's Guide"

I/O module information that is changeable online

The following table shows whether each item of I/O module related information can be changed by online change downloading.

Table E1.3-6 I/O module

Modification	Online change (*1)
Adding nodes	Yes
Deleting nodes	Yes
Changing parameters of nodes	Yes
Adding a unit	Yes
Deleting a unit	Yes
Adding I/O modules	Yes
Deleting I/O modules	Yes
Changing redundant I/O modules	Yes
Changing parameters of I/O modules	Yes
Change in the mounting position (node, unit, and slot) of N-IO I/O module	Yes
Change in the signal category of N-IO I/O modules.	Yes
Changing parameters of channels	Yes
Change in parameters of serial communication modules or Ethernet communication modules	Yes
Defining wiring between a variable and an idle channel	Yes
Deleting wiring between a channel and a variable	Yes
Changing wiring between a channel and a variable	Yes
Addition, change or deletion of subsystem communication definitions	Yes
Changing wiring of communication input/output FBs	Yes
Addition or deletion of ESB bus coupler modules	Yes
Add, change or delete a fire and gas communication definition	Yes
Changing a fire and gas communication FB wiring	Yes

*1: Yes: Online change download is possible.

SEE ALSO For more information about changing hardware, refer to:

- E4., “Replacing FIO node components” in Hardware User's Guide (IM 32P06C10-01EN)
- E5., “Replacing N-IO node components” in Hardware User's Guide (IM 32P06C10-01EN)

Constants and network information that are changeable with online

The following table shows whether the setting can be changed by online change downloading in the constant and network related items.

Table E1.3-7 Constant and network

Classification	Modification	Online Change (*1)
Configuration	Name	No
	Password	No (*2)
Resource	Name	No
	Resource Number	No
	Cycle Timing	Yes
	Memory size for online changes	No
	Memory size for temporary variable	No

Continues on the next page

Table E1.3-7 Constant and network (Table continued)

Classification	Modification	Online Change (*1)
Network	IP address	No
	Station address	No
	Inter-SCS safety Communication (Binding)	No

*1: Yes: Online change download is possible.
No: Offline download is required.
*2: Setting and changing passwords is ignored.

Builder definitions that are changeable with online

The following table shows whether online change download is possible after definition information has been changed using builders.

Table E1.3-8 Builder definitions that are changeable with online

Item	Online Change (*1)
SCS Constants Builder	Yes (*2)
I/O Parameter Builder	Yes
Communication I/O Builder	Yes
SCS Link Transmission Builder	Yes
Modbus Address Builder	Yes
DNP3 Communication Builder (*3)	Yes (*4)
Tag Name Builder	Yes
Alarm Priority Builder	No
Alarm Processing Table Builder	No

*1: Yes: Online change download is possible.
No: Offline download is required.
*2: Some items can be changed online. "Table of SCS Constants Builder online change" shows which items can or cannot be changed online.
*3: Usable only for SCSU1
*4: Some items can be changed online. "Table of DNP3 Communication Builder online change" shows which items can or cannot be changed online.

Table E1.3-9 SCS Constants Builder online change

Item	Online Change (*1)
Interval of Repeated Warning Alarms	No
Synchronous Mode	No
Scan Period for External System	No
Modbus Word Order	No
16-bit Modbus master support mode	No
Alarm Notify Action when AOF Released	No
PV Status of S_ANLG_S	No
The first number of annunciator messages with tag name	No
DNP3 Slave Function (*2)	No
Skip Password Dialog Box for Manual Operation FB (*3)	Yes
Optical ESB Bus Repeater	No
Maximum Extension Distance	No
Extend Scan Period Automatically	Yes

Table E1.3-9 SCS Constants Builder online change (Table continued)

Item	Online Change (*1)
Behavior at Abnormal Calculation	Yes
Locking of Internal Variables (*4)	Yes
Automatic IOM Download	Yes
Device Power-Off Period (*5)	Yes
Device Startup Waiting Period (*5)	Yes
Alarm Suppression During Device Reset (*3)	No
Command Line	No

*1: Yes: Online change download is possible.
No: Offline download is required.
*2: Displayed for SCSU1
*3: Displayed for SCSP3/SCSL2/SCSP2/SCSP1.
*4: Displayed for SCSP3/SCSL2/SCSP2.
*5: Displayed for SCSP3/SCSL2/SCSP2/SCSP1/SCSU1.

Table E1.3-10 DNP3 Communication Builder online change

Items	Online Change (*1)
DNP3 slave station address	Yes
DNP3 master station address	Yes
Timeout value for Select Before Operate (sec)	Yes
Binary Input event buffer size	No
Binary Output event buffer size	No
Binary Counter event buffer size	No
Frozen Counter event buffer size	No
Analog Input event buffer size	No
Analog Output event buffer size	No
Event to be removed when event buffer overflows	Yes
Generate an event when Freeze and Clear command changes data values	Yes
Include Frozen Counters in Class 0 response	Yes
Type of response message fragmentation	Yes

*1: Yes: Online change download is possible.
No: Offline download is required.

E1.4 Online change of scan period of the application logic execution function

The scan period of the application logic execution function can be changed online in the case of SCS with SCS system program R2.03 or later.

Overview of scan period online change

Change the scan period of the application logic execution function with SCS Manager and execute online change download under security level 1 or lower. The SCS will then operate with the specified scan period after download completes. If automatic extension of scan period has been enabled on the SCS, the automatic scan period extension status is cancelled after the completion of online change download and the SCS resumes operation with the scan period specified with the online change.

Limitations on online change

The allowable range of change is the same as the allowable range of specification, i.e., from 50 ms to 1000 ms in increments of 10 ms. Note that in online change, it is not allowed to set a scan period longer than the scan period before change by more than 250 ms. If such changes are made, an error occurs at online change download.

Example:

It is possible to change the scan period from 250 ms to 500 ms. Change from 250 ms to 550 ms is not allowed because it represents an increase of 300 ms.

When changing to a shorter scan period, a dialog box appears, showing the expected CPU idle time after the scan period is changed. You cannot download if the expected CPU idle time is 0 second.

TIP

On the SCS Simulator, the expected CPU idle time is not estimated. Only a dialog box is displayed, informing that the scan period has been changed.

Occurrence of IOM download at online change download

If the scan period defined before or after execution of online change is longer than 250 ms, IOM download processing is executed for all AIO/DIO modules used in the given SCS to notify the change of fallback time. In this case, a confirmation dialog box appears at the start of online change download.

- There is no influence on control operation during online change download because the control of AIO/DIO modules continues.
- Online change download on SENG is completed after the completion of IOM download to all AIO/DIO modules. IOM download takes approximately 5 seconds per module.

If an online change download that changes the scan period is executed, IOM download is executed for all N-IO modules used in the SCS.

- While IOM continuous download is in progress for N-IO modules, control of the N-IO modules continue. Safety loops will not be affected by the execution of IOM downloads.
- After the IOM downloads for all N-IO modules are completed, the online change download is regarded as completed on the SENG. The IOM download for N-IO modules takes about two seconds per module.

SEE ALSO

For more information about the results of analysis by Cross Reference Analyzer when the scan period is changed, refer to:

"● Changing Scan period" on page C5-38

Notification of scan period online change

When online change download performed at scan period change is completed, the diagnostic information message of scan period online change (No. 4152) is notified, in addition to the diagnostic information message of online change download completion.

E1.5 Precautions for online change

This section describes precautions for online change of an application.

Cross Reference Analyzer

- User should confirm locations required for a retest by checking the output of Cross Reference Analyzer.
- For interference -free applications, it is also required to analyze and test parts that are potentially affected by application modifications as with safety applications.

Online change download

- When Online Change Download is executed on I/O modules, confirm that download is executed on the correct I/O modules by checking the diagnostic information message from SCS.
- In CENTUM Integration engineering, even if the correspondence of an instance name and tag name is changed, the modified location may not be displayed in the Cross Reference Analyzer nor in the diagnostic information message. Users must conduct tests very carefully.
- After performing an online change, confirm that the CPU idle time of SCS is sufficient and the scan timing is appropriate.
- When the CPU module is in a dual-redundant configuration, avoid performing online change download during APC (All Program Copy) whenever possible. If online change is executed during APC, the APC is interrupted and starts over again after the online change is finished, which requires longer time to complete APC. This prolongs the duration of operation with a single CPU. This behavior has no impact on safety. The status of APC operation can be confirmed with LED on CPU, SCS State Management window of SENG or Status Display View of HIS. The start and end of APC are notified by diagnostic information messages.
- The maximum number of tag names that can be assigned for monitoring to the annunciators (ANN/ANN_FUP) and function blocks (such as ANLG_S and PASSWD) that allow the assignment of mapping blocks are as follows:
  - Up to 2600 tag names can be assigned when using SCSP1/SCSV1
  - When SCSP3/SCSL2/SCSP2 is used, a maximum of 4500 tag names can be assigned.

  The maximum number of online changes that can be made to these tag names and parameters of the mapping blocks and elements at one time is 200. However, online change download may not succeed even if the above condition is met. In this case, the following error message appears in the message display area of SCS Manager.

  ```
  Too much modified data. Make fewer changes, then load.
  ```

  The limit on the number of function blocks when using SCSP1/SCSV1 is as follows:

  (Number of mapping blocks) + (number of annunciator blocks with tag names) + (total number of mapping blocks/elements changed online at one time) ≤ 2800

  When using SCSP3/SCSL2/SCSP2, the minimum number is as follows:

  (Number of mapping blocks) + (number of annunciator blocks with tag names) + (total number of mapping blocks/elements changed online at one time) ≤ 4700

  If this condition is not met, an error occurs in the check performed before online change and the following error code is displayed in the message display area of the SCS Manager.

```
Error Code:0x9443:0x8ec9
```

or

```
Error Code:0x9448:0x8ec9
```

Note that tag names are not mandatory for annunciators. It is recommended to set tag names only for those that are referenced by tag names.

- If online change download is executed while the Communication I/O Lock Window is open, close the Communication I/O Lock Window after the completion of the online change download. Then, open the Communication I/O Lock Window again. A database mismatch error may occur if the Communication I/O Lock Window is not closed.
- If you change the range of an input channel that is defined in I/O parameters and execute an online change download, the input value on that channel changes during the download and IOP may occur.
- While an Output value at fault is being output, if you change any I/O parameter related to the Output value at fault and execute an online change download, the output value on the channel to which the change was made may change during the download.

SCS actions after changing the types of FB instances

The SCS actions during online change download after the types of FB instances or variables are changed are as follows:

- CENTUM integration configuration
  SCS data keeps the values before online change download. When reading with the Tag Name interface from CENTUM station, the read values are the values before executing online change download. Values cannot be written from CENTUM station.
- Modbus Slave Communication
  Loading/writing values from the Modbus master causes an error. The error code is 13 (hexadecimal).

SEE ALSO For more information about the error code in Modbus slave communication, refer to:

"● Response message under abnormal conditions" in "■ Response message from SCS" in F1.7, "Messages communication" in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

Precautions for changing instance name in online change

If you add/change/delete Instance name(s) to/in/from a function block used in POU and online change download, it affects the behavior of the changed function block.(*1) Do not make unnecessary changes to Instance name(s). Adding of Instance name(s) to a function block is required only if External communication function is used.

*1: Each function block is affected differently by online change. Adding/changing/deleting Instance name(s) involves deleting the existing Instance name(s) together with its previous input/output value and internal status, which affects the behavior of FB. Function Blocks that require measures against instance name changes are as follows:

Table E1.5-1 Impact of instance name change(s)

Function Block	Impact	How to Recover/Avoid
OVR_B, OVR_I, OVR_R, OVR_IB, OVR_IR, GOV_B, GOV_IB	If Override is on, it turns off.	Override is repeated from HIS.
PASSWD	If activated, it gets deactivated.	Activate it again from HIS.
PROD_B, PROD_I, PROD_R	An Inter-SCS communication error and recovers later.	Before online change download, lock the output of Consume side.

Continues on the next page

Table E1.5-1 Impact of instance name change(s) (Table continued)

Function Block	Impact	How to Recover/Avoid
MOB_11, MOB_21, MOA	If Data Manual Operation is enabled, output gets FALSE or “0.”	Before online change download, lock the variable of OUT connected to MOB_* or MOA.

Precautions for reusing instances

If you delete an instance of an FB or instance of a variable from a Program and perform online change downloading without deleting it (instance of FB or variable) from the Dictionary and then add it again to the Program, the data in the instance are those before the deletion. If you need to initialize the instance data, restart the SCS.

Precautions related to initial values of variables

Initial values of variables and FB instance parameters are used when fixing values without rewriting them via logic and specifying values before execution of the first scan after starting SCS.

If Type, Dimension, Scope, and Direction, among types and attributes of variables, are changed online, the values are initialized to the initial values specified by Init.Value of the Dictionary. Changes to values are not reflected if only Init.Value of the Dictionary is changed and online change is executed in order to change the initial values.

If you wish to change only the initial values of variables or FB instance parameters via online changes, change the variable names or delete the variables or FB instances once, perform online change download and then perform online change download to add them again.

Writing to flash memory of SCS

- If an error occurs during writing operation to a flash memory, offline download is required.
- If writing operation to the flash memory is interrupted by pulling out the CPU module or cutting off the power, hardware of the flash memory may fail. Before removing the CPU module or cutting off power, confirm that the LED on the CPU module indicating the flash memory writing status, is lit up (not writing).

Online change of scan period

- You can change the scan period of the application logic execution function by using the online change download. When you shorten the scan period, a confirmation dialog box displays the estimated CPU idle time of the SCS after changing the scan period during performing online change download. For the estimated idle time that is displayed, only the change in scan period is considered and the impact due to application change is not considered.
- Do not change both the scan period of the application logic execution function and applications (e.g., addition of logics and I/O modules) at the same time in a single online change download operation. First, change the scan period and perform online change download, check the CPU load of SCS and then change applications.

Reception Interval Timeout Value (OUTT) for Inter-SCS safety communication

In principle, if you set a longer scan period, the transmission interval of inter-SCS safety communication becomes longer. When you change the scan period by online change download, you need to re-adjust the reception interval timeout values (OUTT) of the SCSs that communicate, by inter-SCS safety communication with the SCS for which the scan period is changed.

(This includes the case where the SCS for which the scan period is changed receives data by inter-SCS communication.)

SEE ALSO For more information about precautions when setting OUTT, refer to:

"● OUTT (reception interval timeout value) setting" in "■ Definition of receive data" in A6.2, "Data structure and definition of the SCS link transmission" in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

Reception Interval Timeout Value (OUTT) for SCS link transmission safety communication

If you set a longer scan period, the transmission interval of SCS link transmission safety communication becomes longer. Therefore, you also need to re-adjust the OUTT for SCS link transmission safety communication, as should be done for inter-SCS safety communication.

SEE ALSO For more information about precautions when setting OUTT, refer to:

"● OUTT (reception interval timeout value) setting" in "■ Definition of receive data" in A6.2, "Data structure and definition of the SCS link transmission" in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

Online change of single/dual-redundant specification of AIO/DIO modules

You need to perform the following procedure to change two adjacent AIO/DIO modules in single configuration implemented in FIO node into dual-redundant configuration by using online change download.

1. Disconnect the I/O cables (or terminal blocks) of the modules.
2. If you change two adjacent existing single modules into dual-redundant configuration, pull out one of the modules and then insert it again.
3. Change the definition of dual redundancy specification, and perform online change download.
4. Connect the I/O cables (or terminal blocks).

Immediately after the online change download, the AIO/DIO modules go into the status described in the following warning; however, the state is restored when I/O cables (or terminal blocks) are connected.

CAUTION

- Input module
  An IOM fail occurs and the "input values at error occurrence" specified as the I/O parameters are set to all input channels. The data status changes to BAD.
- Output module
  An IOM fail occurs and the "Output value at fault" specified as the I/O parameters are set to the physical data of all output channels. The module goes to an output disable status.

Online change of I/O module device index

In order to change the device index of an I/O module, you must delete the I/O module and define it again. At the point I/O modules are deleted, the lock status of each channel of the modules is also canceled.
If you change a device index for a module of the same model installed in the same position by online change download, in the case of input modules, 0s (0 for DI and 0.0 for AI) are input to

the application logic at first and then the values from the field are input. In the case of output modules, the channels' outputs are disabled. FALSE for DO and tight-shut value for AO are output. After performing “output enabled operation”, the modules start to output the values of application logic.

Online change of the device index and element numbers for a fire and gas communication module

If you change the device index of a fire and gas communication module (model: S2LP131) and execute online change download, the S2LP131 restarts. The target S2LP131 will be unlocked upon executing the online change download even if you lock the S2LP131 before executing the online change download. Take appropriate measures against restarting of the communication module, such as to lock the outputs of the application logic that is using the data obtained through the target S2LP131.

When you change the element number of a %XW element, lock the outputs of the application logic that is using the FB wired to the element for which the element number will be changed. This is because if you change the element number of a %XW, an unknown value will be input to the FB that is wired to that element.

Online change of channel wirings

This section explains the system behavior when channel assignment is added, deleted, or changed and then online change download is executed. Note that the following cases are also included, in addition to simply adding, deleting, or changing channel assignments.

- When AIO/DIO module definitions are added, channel assignments are also performed at the same time
- When AIO/DIO module definitions are deleted, channel assignments are deleted
- When AIO/DIO module models are changed (when AIO/DIO module definitions are deleted once, then new AIO/DIO module definitions are added, and channel assignments are also performed at the same time)

IMPORTANT

- If you change the channel assignment and download the change, IOM downloading will not start automatically. However, if the I/O parameters are also changed, IOM downloading may automatically start depending on which parameters have been changed.
- When using S2MMM843 or S2MDV843 in an explosion protection system, refer to the following document without fail because the approved values of the explosion protection parameters are different depending on the signal type.

  ProSafe-RS/ProSafe-RS Lite Explosion Protection (TI 32S01J30-01E)

Online change of input channels

After online changing the input channel assignments, the logical data values of the assigned input variables will be set with the initial value of 0 (DI:FALSE; AI:0.0).Then, the values from the I/O modules will be used.

IMPORTANT

If you add the input channel assignment and the application accessing the input variable, and then the two are online change downloaded at once to SCS, 0 is set to the input variable for an instant before the actual values.

In this case, do the online change according to the procedure below:

1. Run online change downloading right after adding input channels.
2. Lock input variables.
3. Run online change downloading right after changing applications.

When the variable names of the previously assigned input variables are changed and online change downloaded, the input variables will immediately take the values from the I/O modules.

Online change of output channels

When the output channel assignments are added online, the added channels will not be able to output the logic values. The logic values can be output only after performing the "Output enable operation."
When the output channel assignments are changed, after online change downloading, the output values may be different from the previous values.

In this case, do the online change downloading according to the procedure below:

1. Lock the output variables.
2. Run online change downloading.
3. Unlock

When the variable names of the previously assigned output variables are changed and online change downloaded, the output channels will continuous to output the values through I/O modules.

Lock status at online changing of channels

When a locked channel is deleted from the assignment, the lock status of that channel will be released and deleted from the total number of locked channels of the whole station. Once a locked channel is deleted from the assignment and online change downloaded, the lock status of the channel will not be kept even when the channel is added to the assignment and online downloaded again.

Channel status at online changing

If the definition of assigned channels is deleted in online change to make them unassigned, the changed channels behave same as the other channels that are unassigned. As the result, channel status outputs for the system function block (such as CHn of SYS_OUTST or Q of SYS_CHST) become FALSE. Also the changed channels are excluded from representative alarm for the system function block (such as NRAL of SYS_OUTST, NRO of SYS_IOALLST, IOER of SYS_DIAG) and are not considered for diagnostic information marks on the SCS State Management window.

System alarm messages at online changing

When a channel that is causing an error is deleted from the assignment and online change downloaded, the recovery message for the channel will not be raised.

Operating mode at online changing

When an output disabled channel is deleted from the assignment and then online change downloaded, and the operating mode of the station may become Running due to the station does not have any output disabled channel. When an output channel is added to a station that in Running mode, and then online change downloaded the assignment, the status of the station may become Waiting due to the added channel is started in the output disabled status.

Online change of SCS link transmission

- Sequence of Adding and Deleting
  When adding a new data, it should be added first on the sender station. When deleting a data, it should be deleted from the receiver station. Doing this way is to avoid the application to access the deleted data.
- Lock the Link Transmission Data
  The link transmission data can only be locked together for the whole station. Locking one link transmission data, all the link transmission data in the station will be locked.

  Thus, when performing online change (adding or deleting) for link transmission data, the influence of the change to the logics should be properly checked, and then lock the proper variables at the proper places (such as link transmission data of sender station, link transmission data of receiver station or other individual internal variables).

IMPORTANT

For applications that require individual lock, connect the internal variable to lock them as follows:

- On Sender Station: Connect an internal variable to the input parameter of the link transmission output FB, and then lock it.

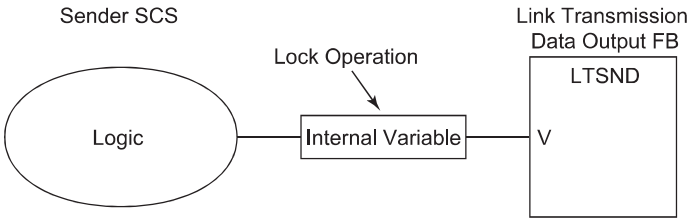

Figure E1.5-1 Lock on sender station

- On Receiver Station: Connect an internal variable to the output parameter of the link transmission input FB, and then lock it.

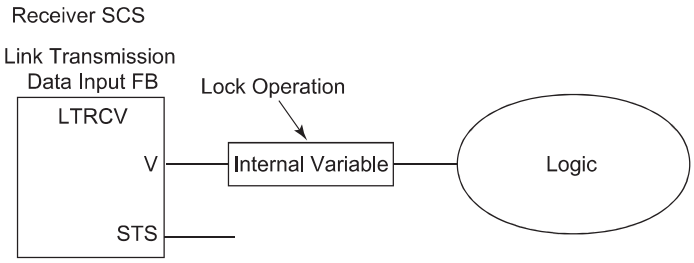

Figure E1.5-2 Lock on receiver station

- Add a logic that uses a link transmission data input FB

IMPORTANT

Do not add a link transmission data input FB and the logics connected to the FB at the same time during the online change. The influence to other logics may occur even if the link transmission received data are properly locked.

In this case, do the online change according to the procedure below:

1. Create a link transmission data input FB.
2. Online Change Download
3. Add a logic connecting to the link transmission data input FB.

- Change the Link Transmission Data Input FB Instance Name
  When a link transmission data input FB instance name is online changed, note that the output of the FB may become different.

  When changing the instance name online is necessary, do it according to the procedure below:

  1. Lock the internal variable that connected to the link transmission data input FB.
  2. Online Change Download

  If you cannot find a proper internal variable to lock, you need to add an internal variable to the output parameter of the link transmission data input FB, and then lock the variable. Then you can online change the instance name.

- Delete Link Transmission Data Output FB
  When a Link Transmission Data Output FB is deleted, the output data will be reset to 0. Even if the local station is locked to avoid bad influence, the receiver side is still affected since the linked data is reset to 0. Therefore, the FB in the receiver side should be deleted first.

- When Sending Definition of the SCS Link Transmission is Disabled
  When sending definition of the SCS link transmission is disabled during online change, data sending to other stations will stop. If another station is receiving data from the stopped station, the actions are shown as follows.

Table E1.5-2 Actions of Receiver Station

Receiver Station	Description
SCS	Since the updating of the safety information (such as sequence numbers or transmission timestamps) sent through the link transmission are stopped, an error will be indicated. The statuses of related input data will become BAD.
FCS	The last received data will be kept. The statuses of the related data will not become BAD.

Moreover, when the transmission size of the sender FCS is online changed to 0, the receiver station on SCS side will keep the last received data values. The data statuses will not become BAD.

Locking Inter-SCS safety communication and SCS link transmission data at online change

False trips caused by online changes can be prevented by locking inter-SCS safety communication data or link transmission data on the station where online change is performed. It is not necessary to lock data on the stations that receive data from the station where online change is performed.

The following figure illustrates an overview and the procedure for performing online changes.

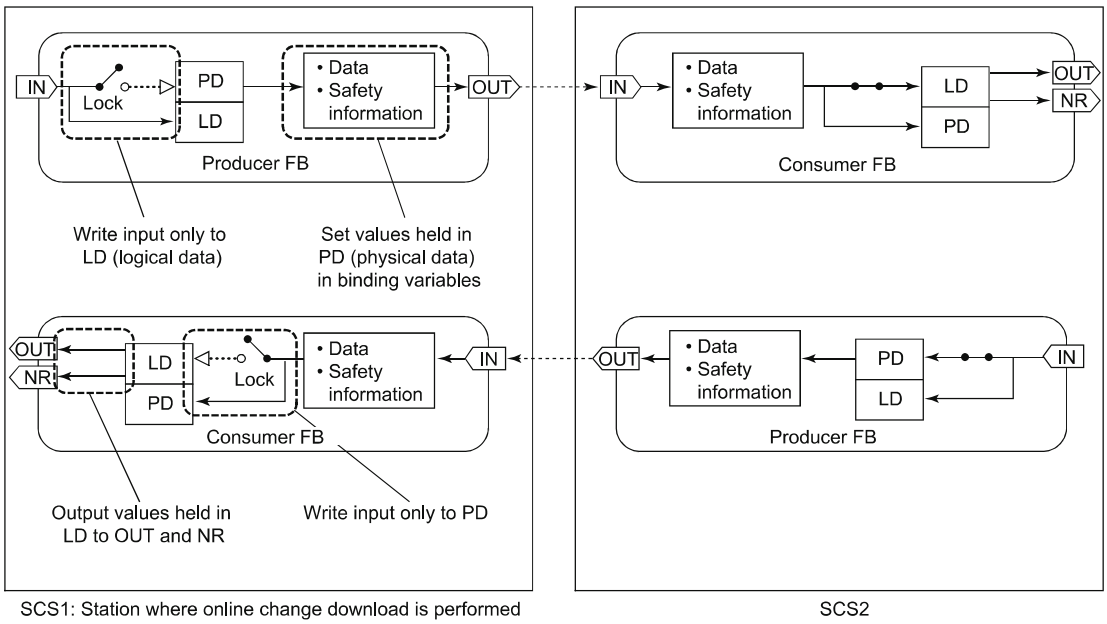

Figure E1.5-3 Example of locking Inter-SCS safety communication at online change

Follow these steps to perform online changes:

1. Set the security level of the SCS for which online change is to be performed to 1.

   Check that the SCS's security level has changed to 1 with diagnostic information messages.

2. Open the Inter-SCS Communication Lock Window or SCS Link Transmission Window of the SCS for which online change is to be performed and lock the sending and receiving data.

   Check that inter-SCS safety communication or link transmission safety communication has been locked with diagnostic information messages.

3. Execute online change download.

4. Check that the logical data and physical data match and that the data status is GOOD in the Inter-SCS Communication Lock window or SCS Link Transmission Lock window.

5. Unlock the sending and receiving data in the SCS in the Inter-SCS Communication Lock window or SCS Link Transmission Lock window.

   Check that the inter-SCS safety communication is unlocked with diagnostic information messages.

6. Set the security level of the SCS for which online change has been performed to 2.

   Check that the SCS's security level has changed to 2 with diagnostic information messages.

Online change download of input/output modules

In the online change download, you can perform changes in the redundant configuration, addition and deletion of I/O modules. If I/O modules are added through online change download, diagnostic information messages are issued to notify failure of I/O modules (No. 0081) and normal recovery of I/O modules (No. 0082).

Online change download of AIO/DIO module settings

When you perform online change download after you have made changes to the settings related to I/O parameter of AIO/DIO modules, IOM download may also take place depending on

the setting items you have changed. The AIO/DIO module continues its I/O operations when IOM download also takes place along with the online change download. The behavior of the SCS is as follows:

- The target modules continue their input/output operations.
- For AIO/DIO modules in redundant configuration, control rights are retained.
- The diagnostic information message of IOM Fail is not output.

Precautions related to fire and gas communication modules when downloading an online change onto SCS

Before online change downloading onto SCS, a dialog box asking the lock of S2LP131 may appear. In such case, before online change downloading onto the SCS, lock the S2LP131 shown in the dialog box. Lock by locking all inputs or by locking all communication definitions.

When not locking all inputs or all communication definitions, the following phenomenon will occur:

- The status of the LD (logical data) of Safety and Non-Safety data obtained via S2LP131 changes to Error.
- The locks of communication definitions partially locked may be released.

As these issues will lead to an unnecessary shutdown of the plant, lock S2LP131 before on-line change downloading.

E1.6 Precautions for online change download of N-IO

This section describes the I/O operation and extent of impact when online change is performed for definitions related to N-IO. Other than the online change of definitions in regard to N-IO, precautions are the same as those for online change download of FIO.

IMPORTANT

When using S2MMM843 or S2MDV843 in an explosion protection system, refer to the following document without fail because the approved values of the explosion protection parameters are different depending on the signal type.

ProSafe-RS/ProSafe-RS Lite Explosion Protection (TI 32S01J30-01E)

SEE ALSO For more information about precautions for online change download of FIO, refer to:

E1.5, “Precautions for online change” on page E1-20

Changing N-ESB bus coupler modules

When you add/delete N-ESB bus coupler module to/from the CPU node, the I/O operations at the I/O modules, other than the N-IO nodes at the connection destination, remain unaffected.

Changing N-IO nodes

When you add or delete an N-IO node, the I/O operations at the I/O modules, other than the related nodes, remain unaffected.

Even when you perform online change for the setting values of N-IO nodes, I/O of the related nodes remain unaffected.

Changing I/O modules of N-IO nodes

The configuration information of an I/O module is downloaded in either of the following ways:

- IOM continuous download: A download wherein the I/O operations at the points other than the changed points continue.
- IOM initialization download: A download wherein the I/O operations of all points of changed I/O modules stop.

In the online change with IOM download, IOM continuous download is executed. During the IOM continuous download, the I/O operations continue.

When you add an I/O module, IOM initialization download is executed. After the IOM initial download, the operation at the IOM startup is executed.

When you add or delete an I/O module, only the I/O operations of the related I/O module are affected.

The deleted I/O module will be in the fall-back state due to being separated from the CPU. This is the same as when the I/O module of the FIO node is deleted.

■ Changing the channels of the I/O module of the N-IO node

When changing the signal type of the channels of the universal type I/O module, you need to reassign I/O variables that are appropriate for the type of signal to which the change is being made.

When the channel being deleted (subject to deletion of variable assignment) is locked, the locked status will be released after the channel is deleted.

Changing the channel assignment is the same as with the I/O module of the FIO node with the exception of the status of the deleted channel.

TIP

The deleted channel will be in an undefined state with the universal type I/O module.

SEE ALSO

For more information about change of channel wirings, refer to:

"■ Online change of channel wirings" on page E1-24

■ Changing the signal category of channels (only for universal type I/O modules)

When changing the signal category of the channels of the I/O module, you need to reassign I/O variables that are appropriate for the category of signal the change is being made to. When you have changed the signal category of channels, IOM download is executed. The operation of the I/O module after download is completed is as follows:

● Changing to a different signal category input

When you change the channel of I/O module to input of a different signal category, after the internal change process in the I/O module completes, the values are newly read from the fields.

TIP

The logical data that is configured to the channel will differ depending on the signal category before and after the change.

- When changing from AO to DI, DO to AI, AI to DI, or DI to AI
  After "0" (FALSE for DI, 0.0 for AI) is configured for the logical data, the input value from the channel is reflected.
- When changing from AO to AI, DO to DI, AI to AI, or DI to DI
  After the value from before the change is configured for the logical data, the input value from the channel is reflected.

When you change the signal category from current input (AI) to current input with HART (AI_HART), or, from current input with HART (AI_HART) to current input (AI), the channels continue their operation even during IOM download. In this case, you do not need to reassign the I/O variables.

● Changing to a different signal category output

When you change the channel of I/O module to output of a different signal category, after internal change process in the I/O module completes, DO outputs 0 and AO outputs tight-shut output value to the field. The output values from the application logic will be output to the field after you perform the output enable operation.

When you change the signal category from current output (AO) to current output with HART (AO_HART), or, from current output with HART (AO_HART) to current output (AO), the channels continue their operation even during IOM download. In this case, you do not need to reassign the I/O variables.

Changing to a high current output

You can change from a high current output type signal to a signal of other type or category by online change.

- When changing from status output (DO) to high current output (DO_1.3A or 2A), or, from high current output (DO_1.3A or 2A) to status output (DO), you do not need to reassign the I/O variables.
- When changing from the output other than status output (AI, AO, DI) to high current output (DO_1.3A or 2A), or, from high current output (DO_1.3A or 2A) to the output other than status output (AI, AO, DI), you must reassign the I/O variables.

IMPORTANT

If the second and the third channel of the channels that you try to define in DO of high current output are already defined as a different channel, the intended channels cannot be defined in the high current output.

The channels that are changed to high current output (DO_1.3A or 2A) will output 0 and go into output disable status. The output values from the application logic will be output to the field after you perform the output enable operation. Only the channels that are targeted for online change are affected.

Operating mode upon online change of the channel signal category

The changes of the operating mode upon online change of the channel signal category are as follows:

- When changing to AO or DO
  The change is the same as when an output channel assignment is added. As the channel for which assignment has been changed will start in a state where output is disabled, the operating mode will be Waiting.
- When changing to AI or DI
  The change is the same as when an output channel assignment is deleted. When output disabled channels no longer exist in the station, the operating mode becomes Running.

SEE ALSO For more information about operating mode upon change of channel wirings, refer to:

"● Operating mode at online changing" on page E1-25

E1.6.1 Procedure for online change download of signal category of channels

There are the following three cases for online change download of the signal category (AI, AO, DI, DO) of channels in the universal type I/O module:

- Change from other than DO to other than DO
- Change from other than DO to DO
- Change from DO to other than DO

IMPORTANT

- You must follow this procedure when performing online change download of the signal category of channels. Otherwise, it may lead to the failure of field devices at the connection destination.
- When you change the signal category from/to DO for a module that is installed on a base plate with disconnecting terminal, disable the ON pulse diagnosis (pulse test (ON) or low voltage pulse test (ON)), set the DO to OFF, and then open or close the disconnecting terminal.
- In the Zone2/Div2 area, removal or installation of barrier cards while they are powered is prohibited. Do not remove or install barrier cards.

Changing the signal category from other than DO to other than DO

Follow these steps to change and online change download the signal category of channels from other than DO to other than DO:

1. Lock the channels to be changed.
2. Perform the following operation based on the type of the base plate used:
   - For base plate with disconnecting terminal
     Open the disconnecting terminals of the channels to be changed.
   - For a base plate with barrier
     Remove the barriers of the channels to be changed from the base plate.
3. On SENG, change the signal category of the channels.
4. Run online change download from SENG.
   When the download is successful, confirm that no abnormality is found in the I/O modules by checking the SCS status display or the LED lamps of the I/O modules.
5. Replace the field devices that are connected to the channels that have been changed.
6. Perform the following operation based on the type of the base plate used:
   - For base plate with disconnecting terminal
     Close the disconnecting terminals of the channels that have been changed.
   - For a base plate with barrier
     Install the barriers of the channels that have been changed on the base plate.
7. Unlock the locked channels.
8. For an output channel, perform output enable operation.

Changing the signal category from other than DO to DO

Follow these steps to change and online change download the signal category of channels from other than DO to DO:

1. Lock the channels to be changed.
2. Perform the following operation based on the type of the base plate used:
   - For base plate with disconnecting terminal
     Open the disconnecting terminals of the channels to be changed.
   - For a base plate with barrier
     Remove the barriers of the channels to be changed from the base plate.
3. On SENG, change the signal category of the channels to DO. At the same time, disable the ON pulse diagnosis of the channels.
4. Execute online change download from SENG.
   When the download is successful, confirm that no abnormality is found in the I/O modules by checking the SCS status display or the LED lamps of the I/O modules.
5. Replace the field devices that are connected to the channels that have been changed.
6. Perform the following operation based on the type of the base plate used:
   - For base plate with disconnecting terminal
     Close the disconnecting terminals of the channels that have been changed.
   - For a base plate with barrier
     Install the barriers of the channels that have been changed on the base plate.
7. As necessary, enable ON pulse diagnosis.
8. Execute online change download from SENG.
9. Unlock the locked channels.
10. Perform the output enable operation.

Changing the signal category from DO to other than DO

Follow these steps to change and online change download the signal category of channels from DO to other than DO:

1. Lock the channels to be changed. When the high current output is set, you need to lock the primary channel only.
2. Perform the following operation based on the type of the base plate used:
   - For base plate with disconnecting terminal
     a. Disable the ON pulse diagnosis of the DO channels.
     b. Execute online change download from SENG.
        When the download is successful, confirm that no abnormality is found in the I/O modules by checking the SCS status display or the LED lamps of the I/O modules.
     c. Perform the output enable operation for the channels that have been changed
     d. Open the disconnecting terminals of the channels to be changed. When the high current output is set, you need to perform the operation for all target channels.
   - For a base plate with barrier
     Remove the barriers of the channels to be changed from the base plate.
3. On SENG, change the signal category of the channels.

4. Run online change download from SENG.
   When the download is successful, confirm that no abnormality is found in the I/O modules by checking the SCS status display or the LED lamps of the I/O modules.
5. Replace the field devices that are connected to the channels that have been changed.
6. Perform the following operation based on the type of the base plate used:
   - For base plate with disconnecting terminal
     Close the disconnecting terminals of the channels that have been changed.
   - For a base plate with barrier
     Install the barriers of the channels that have been changed on the base plate.
7. Unlock the locked channels.
8. For an output channel, perform output enable operation.

E1.7 Online change of subsystem communication modules

This section describes online changes such as the addition/deletion/dual-redundancy specification of subsystem communication modules, changes to settings relating to communication inputs and outputs, the addition/deletion of subsystem communication I/O FBs, and changes to wiring for subsystem communication I/O FBs.

SEE ALSO For more information about precautions during online changes of a subsystem communication module, refer to:

"■ Precautions related to fire and gas communication modules when downloading an online change onto SCS" on page E1-29

■ Locking of subsystem communication data

By locking subsystem communication data, you can reduce the impact of online changes on the application logic or prevent erroneous outputs to subsystems resulting from application logic correction errors.
Subsystem communication data cannot be locked once an online change download is started. Lock subsystem communication data before starting an online change download.

To change a communication input/output definition from any SCS Manager window or builder, close the Communication I/O Lock window first. After the online change is completed, display the Communication I/O Lock window again, if necessary.

Table E1.7-1 Relationship of online changes and locking of communication modules

Content of change	Lock
Change a transmission definition	Required (inputs/outputs need to be locked).
Add, change or delete a communication definition	
Add a subsystem communication I/O FB	
Change the wiring of a subsystem communication I/O FB	
Change an error handling action(*1)	
Delete a subsystem communication I/O FB	Not required.

*1: If a setting is changed while an error occurs, input values will change. Subsystem communication outputs are not affected.

■ Online change procedure

The procedure for making an online change is as follows:

1. Change the application logic and perform build.
2. Check the application logic for consistency using Integrity Analyzer.
3. Check the range to be tested using Cross Reference Analyzer.
4. Change the SCS's security level to Level 1.
5. Lock the inputs/outputs of subsystem communication data in accordance with what you have changed.
6. Close the Communication I/O Lock window.
7. Perform an online change download.
8. Open the Communication I/O Lock window.
9. Test the modified application logic.

10. Unlock the inputs/outputs of subsystem communication data.
11. Reset the SCS's security level to Level 2.
12. Save the SCS project using Version Control Tool.

Addition, deletion, and dual-redundant specifications of subsystem communication modules

Addition, deletion, and dual-redundant specifications of subsystem communication modules can be changed online.

Online changes relating to communication inputs/outputs

When changing a communication I/O setting in the Communication I/O Builder or Safety Communication I/O Editor, also change the wiring of the subsystem communication I/O FB affected by the change.

Online change download

If an online change download is to be performed after a communication input/output data or subsystem communication module setting has been changed, the subsystem communication data of the target subsystem communication module needs to be locked before commencing the online change download. If the subsystem communication data of the target module is not locked, the application logic will be affected by a restart of the subsystem communication module.

The subsystem communication module will restart after the online change download is completed. After the subsystem communication module has been restarted, unlock the subsystem communication data of the module.

Online changes relating to subsystem communication I/O FBs

Adding a subsystem communication I/O FB

If a subsystem communication I/O FB is added, the FB also needs to be wired. If the FB is not wired, a build error will occur.

Before performing an online change download to add a subsystem communication I/O FB, the communication I/O data of the target subsystem communication module needs to be locked.

An online change download to add a subsystem communication I/O FB is performed as a series of multiple scans. Specifically, the subsystem communication I/O FB is added first, and then the wiring is changed. As a result, the added FB is not wired while the online change download is in progress. The subsystem communication I/O FB temporarily assumes the following status during the download:

- Subsystem communication input FB: The data value is 0. The data status is FALSE.
- Subsystem communication output FB: The data value is ignored. The data status is FALSE.

The subsystem communication module will restart after the online change download is completed. Once the subsystem communication module has been restarted, unlock the subsystem communication data of the module.

Deleting a subsystem communication I/O FB

When deleting a subsystem communication I/O FB, also delete the wiring of the FB.

Changing a wiring

Before performing an online change download, the subsystem communication data of the target subsystem communication module needs to be locked. To change the wiring of a subsystem communication I/O FB between two subsystem communication modules, subsystem communication data needs to be locked for the subsystem communication module that contains the wired communication data before the change, as well as the subsystem communication module that will contain the wired communication data after the change. If the data of both modules is not locked, subsystem communication data will be immediately input to the application logic after the online change download is completed, and outputs from the application logic will also be output to subsystems immediately after the download.

Each subsystem communication module will restart after the online change download is completed. Once the subsystem communication module has been restarted, unlock the subsystem communication data of the module.

Changing a POU that includes subsystem communication output FB

To change a POU containing a subsystem communication output FB, the communication output data of the subsystem communication module wired to the applicable subsystem communication output FB needs to be locked.

E2. Import/Export function

The application data of a project can be exported to an external file, and the application data in an exported file can also be imported to a project. This function can be used when diverting or regenerating SCS projects during SCS expansion or reformation.

This function cannot be used together with iDefine projects. Application data that was created by using iDefine need to be controlled under the project management by iDefine.

E2.1 Precautions concerning import/export

This section summarizes the precautions to take when you perform an import or export. You must observe these precautions when carrying out the actual operation.

Outline of import/export

The import/export functions support modifying and reusing SCS project databases. Import/export should be executed from AD Organizer or SCS Manager, depending on the purpose. For example, execute import/export by using SCS Manager for data that is managed by SCS Manager.

However, some of the targets of import/export using SCS Manager will differ depending on the engineering method.

Precautions on compatibility (including import from builders)

- When importing the files created in the previous software release number of SENG, the setting values for the new items supported only in the newer software release number of SENG will be the default values.
- The files exported from the project created on newer software release number SENG cannot be imported to the project opened on the older software release number SENG.

Precautions on password

When importing a project to replace an old project, the passwords of project and POUs are also imported and the old passwords will be replaced.

Therefore, when using export and import, you should manage the project password and the passwords of POUs for exported project.

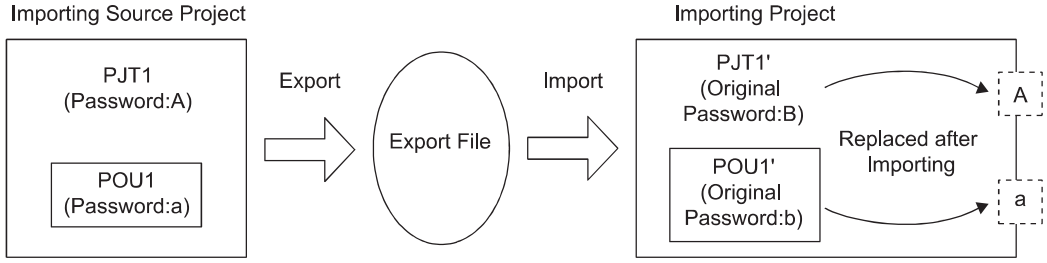

Figure E2.1-1 Passwords replaced after importing

The effects regarding passwords after importing are shown as follows:

- When importing the exported project files with passwords, the passwords of exported project and POUs are also imported and the existing passwords will be replaced. After importing, the passwords of the imported project will be required to open the project, without the passwords, the imported project cannot be opened for editing.
- When importing those POUs that are protected by passwords, the passwords of the existing POUs will be replaced by the passwords of the imported POUs. So, after importing, the passwords of the imported POUs will be required to open the POUs, without the passwords, the imported POUs cannot be opened for editing.

How imported POUs are handled in Cross Reference Analyzer

If the POU to be imported has an identical name with an existing POU, the Cross Reference Analyzer will act as follows:

If the POU to be imported is exactly the same as the existing POU, the Cross Reference Analyzer will mark the POU as "Unchanged POU" and display it in green icon. If the POU to be imported is discrepant from the existing POU, the Cross Reference Analyzer will mark the POU as "Changed POU" and display it in red (Modified) icon.

How to check when project data is migrated by export or import

How to check differences in the imported data after migration of project data by import/export is as follows:

Table E2.1-1 Builder definitions and how to verify

Builder	Data	How to Verify
SCS Manager	POU	Cross Reference Analyzer
	I/O Wiring	Cross Reference Analyzer
	Binding	Cross Reference Analyzer
SCS Project Properties	Domain/Station number	Project Comparing Tool
	CENTUM Project Folder	Project Comparing Tool
Configuration Properties	Target	Project Comparing Tool
	Memory size for temporary variables	Project Comparing Tool
Connections	IP Address	Project Comparing Tool
Resource Properties	Resource Number	Project Comparing Tool
	Cycle Timing	Project Comparing Tool
	Memory size for online changes-Code	(Fixed value) (*1)
	Memory size for online changes-User variable size	Project Comparing Tool
SCS Constants Builder	Interval of Repeated Warning Alarms	Project Comparing Tool
	Synchronous Mode	Project Comparing Tool
	Scan Period for External System	Project Comparing Tool
	Modbus Word Order	Project Comparing Tool
	Alarm Notify Action when AOF Released	Project Comparing Tool
	PV Status of S_ANLG_S	Project Comparing Tool
	Optical ESB Bus Repeater/Maximum Extension Distance (*1) SCS Constants Builder	Project Comparing Tool
	Extend Scan Period Automatically (*1)	Project Comparing Tool
	Behavior at Abnormal Calculation (*1)	Project Comparing Tool
	Automatic IOM Download (*1)	Project Comparing Tool
	Locking of Internal Variables (*1)	Project Comparing Tool
	Device Power-Off Period (*1)	Project Comparing Tool
	Device Startup Waiting Period (*1)	Project Comparing Tool

	16-bit Modbus master support mode	Project Comparing Tool
	DNP3 Slave Function (*1)	Project Comparing Tool
	Skip Password Dialog Box for Manual Operation FB (*1)	Project Comparing Tool

Continues on the next page

Table E2.1-1 Builder definitions and how to verify (Table continued)

Builder	Data	How to Verify
I/O Parameter Builder	Node parameter (Extends Node Bus/ Extends To (Km) for Optical ESB Bus Repeater) (*1)	Project Comparing Tool
	Module parameter	Cross Reference Analyzer
	Channel parameter	Cross Reference Analyzer
Communication I/O Builder	Communication I/O definition	Cross Reference Analyzer
	Communication I/O wiring	Cross Reference Analyzer
SCS Link Transmission Builder	SCS Link transmission data definition	Cross Reference Analyzer
	Wiring definition	Cross Reference Analyzer
Modbus Address Builder	-	Project Comparing Tool
DNP3 Communication Builder (*1)	-	Project Comparing Tool
Tag Name Builder	-	Project Comparing Tool
Alarm Priority Builder	-	Project Comparing Tool
Alarm Processing Table Builder	-	Project Comparing Tool

*1: The corresponding item may not exist or the configurable value may be different depending on the software release number of the system or SCS type. Such items may therefore be picked up as discrepancies by the Project Comparing Tool.

E2.2 Export/import using AD Organizer

This section describes the procedures for exporting/importing SCS project data by using AD Organizer and the procedure for deleting an SCS project by using AD Organizer.

TIP

When engineering by using iDefine, the engineering data that was defined by using iDefine is also imported and exported to SCS projects. In addition, the setting information on FB types to be converted to instances is also included. The iDefine project itself is not imported or exported.

Exporting SCS projects

You can export SCS projects to a specified location. The export file includes SCS project information defined in SCS Manager, the safety I/O, safety communication I/O, nodes, and IOM definitions under the corresponding SCS project in AD Organizer but does not include history information. Follow these steps to export an SCS project:

1. On the System Structure Navigator, select one or multiple SCS projects.
2. Right-click and select [Export SCS].
   The Select Folder dialog box appears.
3. Specify the folder to which the project is to be exported and click [OK].
   When the export is complete, the following result appears.
   - All exported SCS projects
   - List of files at the export destination
   - List of SCS projects for which export failed and reasons of failure

Importing SCS projects

You can import the exported SCS projects. You can specify the SCS projects that were exported from the same AD project or different AD projects, and import them into the RS project.

You need to perform the following procedure to import the project:

1. On the System Structure Navigator, select the RS project folder.
2. Right-click and select [Import SCS].
   The Import SCS dialog box appears.

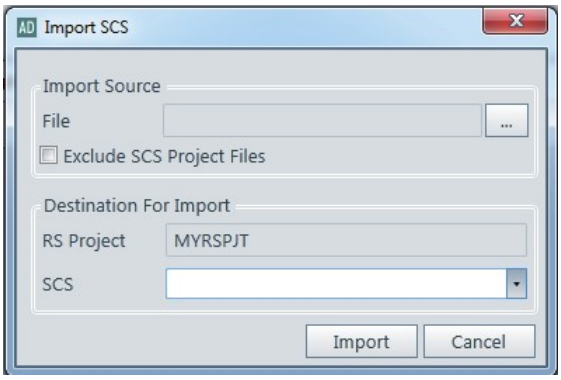

Figure E2.2-1 Example of SCS project import settings

3. Click the […] button on the right side of [File] text entry box and select one SCS project to be imported.
   If you want to import the SCS data other than the data of the SCS project in the specified folder, select the [Exclude SCS Project Files] check box.
4. Perform either of the following operations:
   - From the [SCS] drop-down list, select the SCS name of the import destination.

- Enter a new SCS name.

5. Click the [Import] button.

   If you selected an SCS name from the [SCS] drop-down list, the existing SCS project is overwritten.

   If you entered a new SCS name, a new SCS project is created. Using SCS Manager, change the setting items of the new SCS project to the appropriate values.

Responding to an error when importing an SCS project

- If an error occurs when you import an SCS project, do the following:
  - If the error is due to duplicate P&ID tags, the corresponding safety I/O list and safety communication I/O list are imported in a checked-out state. Start Safety I/O Editor or Safety Communication I/O Editor, correct the P&ID tag, and then perform a check-in.
  - If the error is due to a missing P&ID group, create a safety I/O list or safety communication I/O list with the name of the P&ID group that you want to set under the [I/O-List] folder in System Structure Navigator.

SEE ALSO For more information about precautions for importing an SCS project including the safety I/O list with the safety I/O parameter profile assigned, refer to:

"■ Importing SCS" on page D1-40

Deleting SCS projects

You need to perform the following procedure to delete the SCS project:

1. Use the Windows function to delete the SCS project data to be deleted from the RS project folder.
2. From the menu bar of the System Structure Navigator in AD Organizer, select [Display] > [Update].
   The status of the target SCS is updated. The SCS projects created with RS original engineering are deleted.
3. To delete the SCS project created with I/O list engineering, specify the target SCS project under the RS project in the System Structure Navigator and click [Delete] on the toolbar.
   All the data under the deleted project of the RS project database is deleted, and the IOM definition information related to the deleted project is deleted from AD Organizer.

E2.3 Importing and exporting data that is managed by SCS Manager

By using SCS Manager, you can export/import the application data that is managed in SCS Manager to/from external files. In addition to SCS Manager, some builders also support exporting to and importing from external files.

TIP

In I/O list engineering, both SCS Manager and AD Organizer are used to import/export project data.

This section describes the importable and exportable files, and whether online change download is possible after the import.

SCS project application data exportable by SCS Manager

The units of application data of an SCS project that can be exported by the SCS Manager and the menu item names displayed under [Export] of the [File] menu are as follows.

Table E2.3-1 Specifying export data and Export menu items

Specifiable export data		Menu item	Detailed menu item
Project	Entire SCS project	Project	Entire Project (*1)
	Defined words		Defined words
Resource	Resource properties	Resource	Properties
	I/O device instances (*2)		I/O Device Instances
	Global variables (*2)		Global Variables
	Wiring variables (*3)(*2)		Wiring Variables
	External bindings (*4)		External Binding
POU		POU	
Variables (*5)		Variables	
Defined words		Defined words	
SCS Project Properties		- (*6)	

*1: If you select this item, all the data shown in the table other than SCS project properties are exported.
*2: The function for exporting data in the format of a PXF file cannot be used while implementing I/O list engineering.
*3: Only wired variables among global and local variables are exportable.
*4: Only binding variables among global variables and binding groups are exportable.
*5: When I/O list engineering is being implemented and data is being exported in the CSV format, the variables reflected from Generation Manager will not be exported while all other variables will be exported.
*6: You cannot use the [File] menu to export SCS Project Properties. To export SCS Project Properties, start the Engineering Launcher in SCS Manager, and use the [Export] button in the SCS Project Properties dialog box.

Application data imported by SCS Manager

When you import data from data files of an SCS project using SCS Manager, you can import all of the exported data as a whole or selectively import data by specifying only the lower-level data units you want to import. When you import data from other data files, all of their exported data will be imported. However, if any of the project name, configuration name or resource name in the data file for import do not match their counterparts in the destination project, an error dialog box appears and the import ends up in a failure.

Table E2.3-2 Application data selectable for import

File format	Exported data file	Data unit selectable for import
Binary (PXF format)	Entire SCS project	Project
		POU (you can select multiple POUs)
	Defined words	Defined words
	Resource properties	Resource properties
	I/O device instances	I/O device instance (*1)
	Global variables	Global variable (*1)
	Wiring variables	Wiring variable (*1)
	External bindings	External bindings
	POU	POU
Text (CSV format)	Variables	Variable (*2)
	Defined words	Defined words
	SCS Project Properties (*3)	SCS Project Properties

*1: The import function cannot be used while implementing I/O list engineering.
*2: When performing I/O list engineering, variables of the same name as the variables reflected from Generation Manager will not be imported while all other variables will be imported.
*3: The operations to import SCS Project Properties differ from those for other data. Import using the [Import] button of the SCS Project Properties dialog box.

IMPORTANT

Files with the same software revision number for SENG can be imported. Using SENG to open an SCS project created with an earlier version will make it possible to import that file as well.

Availability of online change download is determined for the imported application data based on the same conditions as those for the change of application data without using an import.

Builders supporting import/export

The table below shows a list of builders that support Import/Export and whether the 'online change download' is allowed for the imported builder files.

Table E2.3-3 Builders supporting import/export and online-changeability of their files

Builders supporting Import/Export	Online change download (*1)
SCS Constants Builder	No (*2)
I/O Parameter Builder	Yes
Communication I/O Builder	Yes
SCS Link Transmission Builder	Yes
Modbus Address Builder	Yes
DNP3 Communication Builder (*3)	No (*4)
Tag Name Builder	Yes
Alarm Priority Builder	No
Alarm Processing Table Builder	No

*1: Yes: Online change downloading possible
No: Online change downloading not possible
*2: Items for which online change download can and cannot be performed both exist in items configured in the SCS Constants Builder. Check the link included at the end of this section.
*3: Export/Import is possible only for the SCS projects of SCSU1 that are created by the software version R3.02.20 or later.

*4: Items for which online change download can and cannot be performed both exist in items configured in the DNP3 Communication Builder. Check the link included at the end of this section.

IMPORTANT

If you import text files that were exported from builders, do not edit the exported files before you import them. Only the text files that were exported from builders are importable; do not import other files.

Exporting a Builder file: On the [File] menu, click [External File] and then click [Export]. The data of the Builder file of the currently opened Builder is exported to an external file.

Importing a Builder file: On the [File] menu, click [External File] and then click [Import]. The data that was exported to the external file is imported and the data of the imported Builder file is shown in the currently opened builder window.

SEE ALSO For more information about whether online change download is possible for each definition item in the builder, refer to:

"■ Builder definitions that are changeable with online" on page E1-16

■ Precautions on handling CSV files

Do not edit CSV files that are exported from SCS project data by using an editor. If you import an edited CSV file in SCS project data, the operations are not guaranteed.

■ Precautions on the importing sequence

When importing individual global variables or individual POUs, the sequence of importing is as follows:

1. POU (Function Block)
2. POU (Other than Function Block)
3. Global Variables

- If you import global variables before importing the POU (Function Block), the Type information regarding the imported global FB instance may be missing. As a result, "???" will be shown in the Type column of Dictionary.
- If you import POU (other than Function Block) before importing the POU (Function Block), the Type information regarding the imported local FB instance may be missing. As a result, "???" will be shown in the Type column of Dictionary.
- If a user-defined function block (such as FB1) is using another user-defined function block (FB2) as a local parameter and FB1 is imported before FB2, the Type information regarding the imported local parameter type may be missing. As a result, "???" will be shown in the Type column of the parameter in Dictionary. The function blocks used as parameters should be imported before.

If the above sequence is not observed when importing the individual global variables or POUs, a build error will occur. In this case, import again in the above-mentioned order.

■ Unit for exporting and sequence of importing

This section describes the file formats that are used when exporting SCS project data and actions that are carried out while importing. SCS projects can be exported as binary (PXF format) files. SCS project properties and SCS constant data can be exported in CSV files.

Import/export in PXF format

Even if you have exported data for individual SCS projects in binary (PXF format) files, you can import data selectively (you can import the POUs you need) from the exported data.

The actions during importing are shown in the following table.

Table E2.3-4 Actions during importing

Imported Contents	Actions during Importing
Project	Deletes the existing project first and then adds the imported project in PXF files. Importing projects is only possible when the project name, configuration name and resource name of the source project match with those of the existing project.(*1)
POU	• Deletes the existing POU with the identical name when adding the POUs from PXF files. • POU name can be changed during importing. • When you import multiple POUs at one time, you can choose whether to import them without changing their name (by deleting any existing POUs and adding them with the same name) or by automatically renaming any POUs with the same name to non-duplicate names. • When importing a local instance where the FB is not defined in the existing project, the variables with unknown types will be generated and build error will occur. To solve this problem, you can either define a new FB before importing or import the FB.
Resource properties	Overwrites all the existing properties of the resource.
I/O device instances (*2)	• If the imported I/O device has different index number with the existing I/O modules, the imported I/O device will be added as a new I/O module. • If the imported I/O device has an identical index number with the same type of existing I/O module, the IOM parameters (node address, slot numbers and redundancy setting) of the imported I/O device will be added to replace the existing I/O module. • If the imported I/O device has an identical index number with a different type of existing I/O module, a warning message will be displayed and the I/O device will not be imported. The existing I/O module will not be changed.
Global variables (*2)	• If the imported variable is different from the existing variable, the imported variable will be added as a new variable. • If the name and scope of the imported variable are identical with the existing variable, the imported variable will be added to replace the existing variable. • If the existing variable is wired with other variable in the same channel, the imported variable will replace the existing variable and be wired with the other variable. • When importing an instance where the FB is not defined in the existing project, the variable with an unknown type will be generated and a build error will occur. To solve this problem, you can either define a new FB before importing or import the FB.
Wiring variables (*2) (I/O variables)	• If the imported variable is different from the existing variable, the imported variable will be added as a new variable. • If the name and scope of the imported variable are identical with the existing variable, the imported variable will be added to replace the existing variable. • If the existing variable is wired with other variable in the same channel, the imported variable will replace the existing variable and be wired with the other variable. • When importing an instance where the FB is not defined in the existing project, the variable with an unknown type will be generated and a build error will occur. To solve this problem, you can either define a new FB before importing or import the FB.

Continues on the next page

Table E2.3-4 Actions during importing (Table continued)

Imported Contents	Actions during Importing
Binding	• If the imported binding group has a different group ID from the existing binding group (either Consumer Group or Producer Group), the imported group will be added as a new group. • If the imported binding group has an identical group ID to an existing binding group (either Consumer Group or Producer Group), the imported group will be added to replace the existing group. • If the imported binding variable has different name from the existing binding variable, the imported binding variable will be added in a binding group.
Defined words	• If the imported defined words have a different name from the existing defined words, the imported defined words will be added as a new defined words. • If the imported defined words have an identical name with the existing defined words, the imported defined words will be added to replace the existing defined words.

*1: When importing the entire projects, an error dialog box appears if any one of the project name, configuration name and resource name of the importing source project does not match with that of the existing project.
For instance, if the entire SCS project of SCS0101 is exported, it is not allowed to import the entire project as SCS0102. If you wish to export the entire project and import it to an SCS project with a different name, create a new project with the same name as the importing source project, perform import operation, and then change the project name, configuration name and resource name to the desired names before using the project.
*2: Cannot be imported when I/O list engineering is applied.

Import/export of SCS Project Properties

You can export SCS Project Properties as a CSV file, but this does not mean that all of the data will be applied when you import it. Actions during import are shown in the following table:

Table E2.3-5 Actions when importing SCS Project Properties

Items	Actions during Import
Station Type	Reflected only when importing during new project creation
Database Type	Not reflected
Station Address	Reflected
Domain Number	Reflected
Station Number	Reflected
IP Address	Not reflected
Component Number	Reflected
Version	Not reflected
CENTUM Project Folder	Reflected
SCS Project Attribute	Not reflected
Originally Created	Not reflected

Import/export of SCS constants

SCS constants can be exported in a CSV file. However, when you import the constants, the default value may be used if the setting does not exist, depending on the software release number of your system and the SCS type. If the settable values are different, they will need to be changed. If you do not change them, an error will occur at build time.

SEE ALSO For more information about importing or exporting PXF files and CSV files, refer to:

E2.3, “Importing and exporting data that is managed by SCS Manager” on page E2-7

E3. Modification and reuse of SCS project database

This section describes the procedures for expanding or remodeling an existing SCS project, recreating an SCS project, and so on by using the import/export functions.

The source project and the destination project for import must be registered in different AD projects.

E3.1 Data transfer procedure during expansions/remodeling in modifications where online change is possible

This section describes the procedure for applying the results of making a modification that can be changed online from a user-defined project to the current project. This procedure involves exporting the results from the user-defined project and only importing the data that has been modified into the current project.

TIP If all the changes were made by using iDefine and none was made by using SCS Manager when engineering by using iDefine, importing the same iDefine-config file to the current project reflects all the changes.

IMPORTANT

- Do not forget to import all the modified content.
- Confirm that the current project has not been changed manually before importing.

The overall flow of the procedure is as follows:

1. If a POU included in a library has been modified, first update the original library project with the modifications required, and then copy the modifications to the library of the current project.
2. If an SCS project has been modified, apply the modifications from the user-defined project to the current project.
3. Perform an online change download of the SCS project.

SEE ALSO For more information about importing or exporting PXF files and CSV files, refer to:

E2.3, “Importing and exporting data that is managed by SCS Manager” on page E2-7

Library POU data transfer in modifications where online change is possible

If you are using library POUs, use the Import/Export function to apply the modifications from the library in the user-defined project to the original library.

- By way of preparation, back up the original library using the Version Control Tool.

Exporting library POU source data where online change is possible

Export the library Program Organization Unit (POU) source data.

- Export the data from the library of the project at the origin of the import to create the following PXF file or CSV file.
  - A PXF file of the entire library project.
  - When reflecting the addition/modification of a global variable being used in the library project, create a PXF file or CSV file of the global variable. (*1)
  - When reflecting the addition/modification of a definition word being used in the library project, create a PXF file or CSV file of the global variable (*1)

*1: When performing RS original engineering, create a PXF file. When performing I/O list engineering, create a CSV file.

Importing library POU data where online change is possible

1. Open the original library with SCS Manager and import the required data from the exported PXF or CSV files.
   1-1 In the Import dialog, specify the PXF file containing the entire exported library project and import only the modified POUs (*1)
   1-2 When importing global variables, in the Import dialog box, specify the PXF file or CSV file (*2)that contains global variables and perform the import. Import the data upon making a specification in the import dialog box.
   1-3 When importing defined words, specify the PXF file or CSV file of the defined word in the import dialog box and import (*2)

   *1: In the course of importing, if the POU contains any FB that does not exists in the current project, the following warning message will be displayed. In such a case, a build error will occur when building the project.
   Warning: Type 'UFB' for symbol 'iUFB' was not found in this project.
   or
   Warning: Type 'UFB1' for Parameter 'iUFB1' was not found in this project.
   'UFB', 'UFB1': FB Name
   'iUFB', 'iUFB1': FB Instance Name
   *2: When performing RS original engineering, import the PXF file. When performing I/O list engineering, import the CSV file.
2. Delete any global variables and defined words that are not required after importing. The variables that are not used in POU can be checked in the Browser. Start the Browser and generate (or refresh) the cross-reference information for checking the unused variables.
3. Perform build.
4. Validate the contents on the Integrity Analyzer.
5. Copy the original library to the LIBRARIES folder of the current project.

SCS project data transfer in modifications where online change is possible

Apply the modifications from the modified user-defined project to the current project using the Import/Export function.

- By way of preparation, back up the current project using the Version Control Tool.

Exporting SCS project source data where online change is possible

Export the SCS project data from the import source project.

1. Using SCS Manager, export the data from the project at the origin of the import and create the following PXF file or CSV file.
   - A PXF file of the entire project
   - When reflecting the addition/modification of a global variable, create a PXF file or CSV file of the global variable. (*1)
   - When reflecting the addition/modification of a definition word, create a PXF file or CSV file of the global variable(*1)

   *1: When performing RS original engineering, create a PXF file. When performing I/O list engineering, create a CSV file.
2. If you have modified "Component Number" or "CENTUM Project Folder" in the SCS Project Properties, export the SCS Project Properties to a CSV file. Items other than "Component Number" and "CENTUM Project Folder" cannot be modified via an online change in SCS Project Properties.
3. When performing I/O list engineering, use AD Organizer to export the SCS project at the origin of the import.

SEE ALSO For more information about procedures for exporting an SCS project using System Structure Navigator of AD Organizer, refer to:

"■ Exporting SCS projects" on page E2-5

Importing SCS project data where online change is possible

1. Open the original current project with SCS Manager and import the required data from the exported PXF files.
   1-1. In the Import dialog, specify the PXF file containing the entire exported project and import only the modified POUs (*1)
   1-2. To import the global variables, in the import dialog box, specify the PXF file containing the global variables, and import.
   1-3. To import the defined-words, in the import dialog box, specify the PXF file containing the defined-words, and import.

   *1: In the course of importing, if the POU contains any FB that does not exists in the current project, the following warning message will be displayed. In such a case, a build error will occur when building the project.
   Warning: Type 'UFB' for symbol 'iUFB' was not found in this project.
   or
   Warning: Type 'UFB1' for Parameter 'iUFB1' was not found in this project.
   'UFB', 'UFB1 ': FB Name
   'iUFB', 'iUFB1': FB Instance Name

2. After importing, the unnecessary global variables and defined words should be deleted. The variables that are not used in POU can be checked on the Browser. Start the Browser and generate (or refresh) the cross-reference information to check the unused variables.
3. If you have modified "Extends Scan Period Automatically", "Behavior at Abnormal Calculation", "Locking of Internal Variables", "Automatic IOM Download", "Device Power-Off Period", or "Device Startup Waiting Period" of SCS Constants Builder, correct each of them in the builder. There are no other items in SCS Constants Builder that can be modified via an online change.
4. Regarding the following builders, import the builder files if required.

Table E3.1-1 Builder files for import (modifications where online change is possible)

Builder	Builder File Location (*1)
I/O Parameter Builder (*2)	SCS Project\YOKOGAWA_SCS\SAFETY\IOM\IOMDEFSB.edf
Communication I/O Builder (*2)	SCS Project\YOKOGAWA_SCS\SAFETY\CONFIGURATION\CommIO.edf
Link Transmission Builder	SCS Project\YOKOGAWA_SCS\SAFETY\CONFIGURATION\LinkTrans.edf
Modbus Address Builder	SCS Project\YOKOGAWA_SCS\INTEGRATION\CONFIGURATION\ModbusDef.edf
DNP3 Communication Builder (*3)	SCS Project\YOKOGAWA_SCS\INTEGRATION\CONFIGURATION \DNP3Def.edf
Tag Name Builder	SCS Project\YOKOGAWA_SCS\INTEGRATION\TAG\TAG.edf

*1: Relative path under SCS project top directory
*2: In the case of I/O list engineering, it is not necessary to import the builder files using I/O Parameter Builder and Communication I/O Builder.
*3: Because the event buffer size cannot be modified by an online change, import the event buffer size, and then restore and save the original value.

The builder files of the Alarm Priority Builder and Alarm Processing Table Builder cannot be modified by online change. Do not import them.

5. If "Component Number" or "CENTUM Project Folder" have been changed in the SCS Project Properties, import the CSV file that you exported to in advance.
6. Perform the following operations when performing I/O list engineering:

6-1 Run an SCS import using System Structure Navigator of AD Organizer to reflect the safety I/O list, safety communication I/O list, and IOM information onto the SCS project at the destination of the import.

In the SCS Import dialog box, select the [Exclude SCS Project Files] check box and perform the import.

6-2 If changes have been made with the safety I/O list, safety communication I/O list, and IOM information, perform the build process with RS Generation Manager.

SEE ALSO For more information about build processes of SCS project using Generation Manager, refer to:

D4.4, “Operating procedure of RS generation” on page D4-8

For more information about importing an SCS project using System Structure Navigator of AD Organizer, refer to:

“■ Importing SCS projects” on page E2-5

● Online change downloads during SCS project expansions/remodeling

When you have applied the library POU data and SCS project data to the current project, run the online change download.

1. Perform build.
2. Use the Project Comparing Tool to check that the original project after import is the same as the source user-defined project.
   a. Launch the Project Comparing Tool and clear the [compare imported project] check box to compare the original project after import and the source user-defined project and check that there are no discrepancies. When you do so, check the project path display area of the Project Comparing Tool or the printed discrepancies summary report to make sure that the project paths that you are comparing are correct.
   b. If a discrepancy is found, check that it is appropriate.
3. On Integrity Analyzer, validate the contents.
4. On Cross Reference Analyzer, validate the modified contents. Modifications must also be tested after download.
5. Perform online change downloading.

SEE ALSO For more information about procedures for an online change download, refer to:

E1., “Online change of applications” on page E1-1

E3.2 Data transfer procedure during expansions/remodeling in modifications requiring offline download

This section describes the procedure for making a modification that requires offline download and importing the results of testing in the import source project into the current project on a project-by-project basis. Offline download is necessary because the entire project is being imported.

The overall flow of the procedure is as follows:

1. If a POU included in a library has been modified, first apply the modifications to the library project to the original library project, and then copy the modifications to the library of the current project.
2. If the import source project has been modified, apply the modifications to the current project.
3. Download the SCS project offline.

Library POU data transfer in modifications requiring offline download

Apply the modifications from the library in the import source project to the original library and copy it to the LIBRARIES folder of the current project.

- By way of preparation, back up the original library using the Version Control Tool.

1. Open the library of the importing source project side on the SCS Manager, and change the target name to SCS_TARGET and then save the change.
2. Export the entire project containing the library to PXF files.
3. Use the SCS Manager to open the original library, specify the PXF files thus created in the Import dialog, and then import the whole project containing the library.
4. Execute the build of the original library.
5. Check the integrity of the original library using the Integrity Analyzer.
6. Copy the original library to the LIBRARIES folder of the current project.

SCS project data transfer in modifications requiring offline download

Reflect the modifications on the current project from the modified importing source project.

- By way of preparation, back up the current project using the Version Control Tool.

Exporting SCS project source data requiring offline download

1. Open the importing source project on the SCS Manager, and change the target name to SCS_TARGET and then save the change.
2. Export the entire source project to PXF files.
3. If you have modified "Component Number" or "CENTUM Project Folder" in the SCS Project Properties of the import source project, export the SCS Project Properties to a CSV file.
4. If you have modified SCS Constants Builder in the import source project, export it to a CSV file.

Importing source SCS project data that requires offline download

1. In SCS Manager, open the current project, import the whole project specifying the PXF file exported from the source project.
2. Redefine the library path to the current project.
3. Import the CSV file if there is an exported CSV file of the SCS Constants Builder.
4. Import the builder files if required.

Table E3.2-1 Builder files for import

Builder	Builder File Location (*1)
I/O Parameter Builder (*2)	SCS Project\YOKOGAWA_SCS\SAFETY\IOM\IOMDEFSB.edf
Communication I/O Builder (*2)	SCS Project\YOKOGAWA_SCS\SAFETY\CONFIGURATION\CommIO.edf
Link Transmission Builder	SCS Project\YOKOGAWA_SCS\SAFETY\CONFIGURATION\LinkTrans.edf
Modbus Address Builder	SCS Project\YOKOGAWA_SCS\INTEGRATION\CONFIGURATION\Modbus-Def.edf
DNP3 Communication Builder	SCS Project\YOKOGAWA_SCS\INTEGRATION\CONFIGURATION \DNP3Def.edf
Tag Name Builder	SCS Project\YOKOGAWA_SCS\INTEGRATION\TAG\TAG.edf
Alarm Priority Builder	SCS Project\YOKOGAWA_SCS\INTEGRATION\CONFIGURATION\Alm-Pri.edf
Alarm Processing Table Builder	SCS Project\YOKOGAWA_SCS\INTEGRATION\CONFIGURATION \AlmTbl.edf

*1: (relative path under SCS project top directory).
*2: In the case of I/O list engineering, it is not necessary to import the builder files using I/O Parameter Builder and Communication I/O Builder.

5. Import the CSV file if there is an exported CSV file of the SCS Project Properties of source SCS project.
6. Perform the following operations when performing I/O list engineering:
   a. Using AD Organizer, reflect the safety I/O list, safety communication I/O list, and IOM information onto the SCS project at the destination of the import.
   b. If changes have been made with the safety I/O list, safety communication I/O list, and IOM information, perform the build process with RS Generation Manager.

SEE ALSO

For more information about build processes of SCS project using Generation Manager, refer to:

D4.4, “Operating procedure of RS generation” on page D4-8

For more information about importing an SCS using System Structure Navigator of AD Organizer, refer to:

“■ Importing SCS projects” on page E2-5

Offline download during expansions/remodeling

Execute offline download in an SCS project that you have finished importing.

1. Perform build.
2. Use the Project Comparing Tool to check that the original project after import is the same as the source user-defined project.
   2-1. Launch the Project Comparing Tool and clear the [compare imported project] check box to compare the original project after import and the source user-defined project and check that there are no discrepancies. When you do so, check the project path

display area of the Project Comparing Tool or the printed discrepancies summary report to make sure that the project paths that you are comparing are correct.

2-2. If a discrepancy is found, check that it is appropriate.

3. Validate the contents on the Integrity Analyzer.
4. Validate the modified contents on the Cross Reference Analyzer. Modifications must also be tested after download.
5. Perform offline download.

TIP

- Possibilities of online change download
  Whether or not it is possible to perform online change download when the current project has been modified by import is the same as when the same modifications are made manually on the current project. Therefore, in some cases, online change download is possible even when the entire project has been imported. Whether or not it is possible to perform online change download is found when you run a build or try to run online change download after importing.

E3.3 Data transfer procedure during SCS project regeneration

In order to apply the new features on the newer SENG software release number to the existing SCS project or to reuse the existing project, the existing project needs to be ported (or regenerated).

When porting (or regenerating) a project, the original project needs to be entirely exported into PXF format binary files. Then import the PXF files into a new project.

When performing I/O list engineering, in addition to using SCS Manager, it is necessary to export/import the SCS project by using AD Organizer.

The overall flow of the procedure is as follows:

1. If the library needs to be regenerated, regenerate the library first.
2. Regenerate the SCS project.
3. Check that the regenerated project is equivalent to the original project.

SEE ALSO For more information about importing or exporting PXF files and CSV files, refer to:

E2.3, “Importing and exporting data that is managed by SCS Manager” on page E2-7

Regenerating library data when regenerating an SCS project

Implement the following procedure if you need to regenerate a library as part of regenerating an SCS project.

1. Back up the original library on the Version Control Tool if necessary.
2. Open the source library in SCS Manager and export the whole project containing the library to PXF files.
3. In Windows Explorer, delete the original library, or move it to a different place.
4. Create a new library by using the same name as the source library, and change the related resource names and configuration names to the same names that are used in the source library.
5. In the SCS Manager, import the whole project containing the source library. In the Import dialog, specify the PXF files to which the project has been exported.
6. Build the library.
7. Check the integrity of the library using the Integrity Analyzer.

Regenerating an SCS project with the new revision

Follow these steps to regenerate an SCS project with the new revision:

1. Using SCS Manager, export all of the data in the source SCS project. More specific instructions are given later.
2. If you are upgrading an SCS project that was created by I/O list engineering with a software revision R4.01.00 through R4.03.00, create a safety communication I/O list for the target SCS by using Communication I/O List Output Tool.
3. In System Structure Navigator of AD Organizer, select the target SCS and execute an export of the SCS.
4. In Windows Explorer, move the source SCS project to a work folder.
5. From the menu bar of AD Organizer, select [View] > [Refresh].
   The display of System Structure Navigator is refreshed.

6. For I/O list engineering, in System Structure Navigator of AD Organizer, select the target SCS and start Safety I/O Editor, then delete all I/O rows, save, and check in.
7. If there is no Comm_I/O under the target SCS, proceed to the next step. If there is a Comm_I/O under the target SCS, select the Comm_I/O and start Safety Communication I/O Editor. Delete all rows of Program Definition, Communication Definition, and Signal Definition, save the list, and then check in.
8. In System Structure Navigator, select the target SCS and click [Delete].
9. Using SCS Manager, create a new SCS project by using the same SCS name and location as the source SCS project, and change the related resource names and configuration names to the same names that are used in the source project.
10. Copy any libraries used in the source SCS project to the LIBRARIES folder of the newly created SCS project. Also copy any libraries that you have regenerated.

TIP

When engineering by using iDefine, you do not need to copy the iDefine-config file.

11. In SCS Manager, open the newly created SCS project and import the data that you exported in step 1. More specific instructions are given later.
12. Import the builder files of the source project.
13. If the SCS project has been registered in AD Server, select [View] > [Refresh] from the menu bar of AD Organizer.
    The display of System Structure Navigator is refreshed.
14. When performing I/O list engineering, use System Structure Navigator of AD Organizer to select the target RS project and execute an import of the SCS.
    As the files to import, specify the files that you exported in step 3.

    In the SCS Import dialog box, select the [Exclude SCS Project Files] check box and perform the import.
15. If you are upgrading an SCS project that was created by I/O list engineering with a software revision R4.01.00 through R4.03.00, import the safety communication I/O list that you created in step 2.
16. Start the SCS project build process. In the case of I/O list engineering, run RS Generation from AD Organizer.

SEE ALSO

For more information about build processes of SCS project using Generation Manager, refer to:

D4.4, “Operating procedure of RS generation” on page D4-8

For more information about the procedure for exporting source SCS project data using SCS Manager, refer to:

“● Exporting SCS project data when regenerating an SCS project” on page E3-11

For more information about the procedure for exporting an SCS project using System Structure Navigator of AD Organizer, refer to:

“■ Exporting SCS projects” on page E2-5

For more information about the procedure to import source SCS project data by using SCS Manager, refer to:

“● Importing SCS project data when regenerating an SCS project” on page E3-11

For more information about the procedure for importing an SCS using System Structure Navigator of AD Organizer, refer to:

“■ Importing SCS projects” on page E2-5

For more information about Communication I/O List Output Tool, refer to:

“■ Communication I/O List Output Tool” on page App.3-16

Exporting SCS project data when regenerating an SCS project

1. Back up the original project on the Version Control Tool if necessary.
2. Open the original project on the SCS Manager, export the binding information, and create the PXF file.
3. Export the whole project from the original project and create the PXF file.
4. Export the SCS Project Properties from the source project to create a CSV file.
5. Export the SCS Constants Builder data from the source project to create a CSV file.

Importing SCS project data when regenerating an SCS project

Follow these steps to import data of the source SCS project to the destination SCS project:

1. In SCS Manager, open the newly created SCS project, specify the PXF file to which the binding information of the source project was exported, and import the binding information.
2. In SCS Manager, specify the PXF file to which the whole source project was exported, and import the whole project.
3. Open the SCS Constants Builder and import the exported CSV file in the source project.
4. Import the builder files of the builders that are shown in the following table:

Table E3.3-1 Builder files to be imported (project regeneration)

Builder	Builder File Location (*1)
I/O Parameter Builder (*2)	SCS Project\YOKOGAWA_SCS\SAFETY\IOM\IOMDEFSB.edf
Communication I/O Builder (*2)	SCS Project\YOKOGAWA_SCS\SAFETY\CONFIGURATION\CommIO.edf
Link Transmission Builder	SCS Project\YOKOGAWA_SCS\SAFETY\CONFIGURATION\LinkTrans.edf
Modbus Address Builder	SCS Project\YOKOGAWA_SCS\INTEGRATION\CONFIGURATION\ModbusDef.edf
DNP3 Communication Builder	SCS Project\YOKOGAWA_SCS\INTEGRATION\CONFIGURATION \DNP3Def.edf
Tag Name Builder	SCS Project\YOKOGAWA_SCS\INTEGRATION\TAG\TAG.edf
Alarm Priority Builder	SCS Project\YOKOGAWA_SCS\INTEGRATION\CONFIGURATION\AlmPri.edf
Alarm Processing Table Builder	SCS Project\YOKOGAWA_SCS\INTEGRATION\CONFIGURATION \AlmTbl.edf

*1: (relative path under the SCS project top directory)
*2: In the case of I/O list engineering, it is not necessary to import the builder files using I/O Parameter Builder and Communication I/O Builder.

5. Open SCS Project Properties and import the exported CSV file in the source project.

Regenerating an SCS project with a different station type

Follow these steps to regenerate an SCS project with a different station type.

TIP

If the source SCS project was created by I/O list engineering with a software version earlier than R4.03.10, create a safety communication I/O list of the source SCS by using Communication I/O List Output Tool and load it into Safety Communication I/O Editor in advance.

1. Using SCS Manager, export the entire source SCS project.

- When performing RS original engineering to change from SIL3 SCS to SIL2 SCS, or the other way around, keep a separate record of the definition details of I/O Wiring View and I/O Parameter Builder.

2. When performing I/O list engineering, follow these steps:

   a. In System Structure Navigator of AD Organizer, select the source SCS and start IOM Definition Editor.

   b. Export the defined contents.
   When changing from SIL3 SCS to SIL2 SCS, or the other way around, keep the record of IOM definition details. You can record them for example by copying the definition details and pasting them into a text editor.

   c. In System Structure Navigator of AD Organizer, select a file under the I/O-List folder, start Safety I/O Editor, perform a save after clearing the RS Project column of the I/O assigned to the target SCS, and check in.

   d. In System Structure Navigator of AD Organizer, if there is a Comm_I/O, select it and start Safety Communication I/O Editor, then clear the RS Project column of the program definitions assigned to the target SCS. Because fire and gas communication related definitions are allowed only for S2SC70, delete all such definitions, save the list, and check in.

3. When engineering by using iDefine, specify the iDefine-config file that was imported to the target SCS and save it.
   You can specify the iDefine-config file that was imported to the target SCS by using the revision management function of iDefine.

4. In Windows Explorer, move the source SCS project to a work folder.

5. From the menu bar of the System Structure Navigator in AD Organizer, select [Display] > [Update].
   The display of System Structure Navigator is refreshed.

6. Select the target SCS, and click the [Delete] button on the toolbar.

7. Because the type of SCS is being changed, re-assign licenses to the SCS.

8. In SCS Manager, create a new SCS project with the same SCS name under the original RS project. Definitions of the configuration name and resource number must be the same as the source station.

9. Copy any libraries used in the source SCS project to the LIBRARIES folder of the newly created SCS project. Also copy any libraries that you have regenerated.

TIP

When engineering by using iDefine, you do not need to copy the iDefine-config file.

10. Using SCS Manager, import the PXF files of the SCS that you exported in step 1 to the destination SCS project. Import the exported builder files as well. However, exclude the POUs that cannot be defined in the destination station.

    - When performing RS original engineering to change from SIL3 SCS to SIL2 SCS, or the other way around, change the I/O Wiring View information recorded in step 1 to be appropriate for the destination IOM and define it. Also, change the definition details of I/O Parameter Builder to the recorded details.

11. From the menu bar of the System Structure Navigator in AD Organizer, select [Display] > [Update].
    The display of System Structure Navigator is refreshed.

12. When performing I/O list engineering, in the System Structure Navigator, select a file under the I/O-List folder and start Safety I/O Editor, and then perform the following steps:
    a. In the RS Project column of the destination SCS project, enter the same data as that of the source SCS project. Delete the data that is not supported in the regenerated station, and save.
    b. When changing from SIL3 SCS to SIL2 SCS, or the other way around, change IOM Type to be appropriate for the destination.
    c. Check in the changed details.
13. If you are performing I/O list engineering, select Comm_I/O, if it is defined in the System Structure Navigator, and start Safety Communication I/O Editor, then perform the following operation:
    a. In the RS Project column of the program definition, enter the same data as that of the source SCS project. Delete the data that is not supported in the regenerated station, save the list, and check in.
14. If you are performing I/O list engineering, select the destination SCS in the System Structure Navigator and start IOM Definition Editor.
    a. Click the [Create Node & IOM] button, and create nodes and IOMs.
    b. Create ESB bus coupler modules or N-ESB bus coupler modules as necessary.
    c. Change the node and IOM definition details from the default values to the values defined in the source project. To do this, use IOM Definition Editor to import the file exported from IOM Definition Editor in step 2.
    d. When changing from SIL3 SCS to SIL2 SCS, or the other way around, change the IOM definition details to the values record in step 2-b.

IMPORTANT

- If you export the entire SCSP1/SCSV1 project and import it to a newly created project of SCSP3/SCSL2/SCSP2, the values of the source project are applied to the following definitions related to application capacity. After importing, you must change the values to the fixed values or default values of SCSP3/SCSL2/SCSP2.

Table E3.3-2 Definition items related to application capacity

Definition item	Value of SCSP1/SCSV1	Value of SCSP3/ SCSL2/SCSP2	Remarks
Online change code size (*1)	1700000 (fixed value)	2550000 (fixed value)	A build error will occur if the value is not changed after importing.
Online change user variable size (*2)	32768 (default) 8192 to 65536 (allowable specification range)	131072 (default) 8192 to 262144 (allowable specification range)	A value different from the default SCSP2 value is set after importing.
Constant/temporary variable size (*3)	32768 (default) 8192 to 65536 (allowable specification range)	131072 (default) 8192 to 262144 (allowable specification range)	A value different from the default SCSP2 value is set after importing.

*1: [Code size] in the Advance settings dialog box of the Settings tab in Resource Properties of the SCS Manager
*2: [User variable size] in the Advanced settings dialog box of the Settings tab in the Resource Properties of the SCS Manager
*3: [Memory size for temporary variables] in the Target tab of Resource Properties in the SCS Manager or [Memory size for temporary variables] in the Hardware tab of Configuration Properties in the SCS Manager

- If you are performing RS original engineering and have imported the project data of SCSP1/SCSV1 to an SCSP3/SCSL2/SCSP2 project that uses optical ESB bus repeater, configure the node settings of the I/O Parameter Builder for all FIO nodes connected to the CPU node through the optical ESB bus repeater modules. If [Extends Node Bus] is set to [No], change it to [Yes] and specify the actual node distance to [Extends To (Km)].
- If you import SCSP3/SCSL2/SCSP2 applications to an SCSP1/SCSV1 project, do not import the entire project. Instead, import the engineering data individually, for example, in POU units.

15. If you use iDefine for engineering to change from SIL3 SCS to SIL2 SCS, or the other way around, follow these steps:
    a. From AD Organizer, load the information of new node and IOM into iDefine.
    b. In the POU and tag information defined in iDefine, reflect the new information which was reflected in step a. Next, load the iDefine information by using System Structure Navigator of AD Organizer and reflect it in the new SCS again.
16. Start the SCS build process. In the case of I/O list engineering, run RS Generation from AD Organizer.

SEE ALSO

For more information about how to create nodes & IOM, refer to:

"■ Creating the node and I/O module based on safety I/O list" on page D3-5

For more information about build processes of SCS using Generation Manager, refer to:

D4.4, "Operating procedure of RS generation" on page D4-8

For more information about how to use Communication I/O List Output Tool, refer to:

"■ Communication I/O List Output Tool" on page App.3-16

For more information about the procedure to export SCS project data, refer to:

"● Exporting SCS project data when regenerating an SCS project" on page E3-11

For more information about the procedure to export SCS project data by using SCS Manager, refer to:

"● Importing SCS project data when regenerating an SCS project" on page E3-11

■ Confirming a regenerated project

Check that the regenerated project is equivalent to the original project using the following procedure.

1. Open the regenerated SCS project on the SCS Manager and perform build.
2. Check the validity using the Integrity Analyzer.
3. Using the function of Cross Reference Analyzer for comparison with the original project, check that all POUs are equivalent to those of the original project.
   Open the regenerated SCS project on the SCS Manager and compare it with the original SCS project using the Cross Reference Analyzer. Confirm that all POUs are displayed in green (retesting or review is not required). At this point, check whether the path in the title bar of Cross Reference Analyzer or in the report is correct.
4. For data that cannot be checked with Cross Reference Analyzer, use the Project Comparing Tool to ensure that the regenerated SCS project is equivalent to the original SCS project. When doing so, select the [compare imported project] check box of the Project Comparing Tool.
   Launch the Project Comparing Tool and compare the regenerated SCS project with the original SCS project, so that there is no difference in all items. When you do so, check that the project paths which you are comparing are correct in the project path display area of Project Comparing Tool or in the printed summary report of the discrepancies.
   - If no difference is detected with the Cross Reference Analyzer or the Project Comparing Tool, re-test of SCS application is not required.
   - If the following differences are detected with the Project Comparing Tool, check the details and modify as needed:
     - If you import an SCS project that is created using a SENG with an older software release number, definitions that do not exist in the original project are set to the default values in the regenerated project. These items are picked up as discrepancies by the Project Comparing Tool. When you change the default value, the items must be tested.
     - If you import an SCS project that is created for a different model, definitions that do not exist on the model used for the original project are set to the default values in the regenerated project. Moreover, definitions with different configurable values will produce an error at build in the regenerated project.
5. Perform an offline download to the SCS and make sure that the SCS starts.

TIP

If you have modified a regenerated project after verifying that the regenerated project is equivalent to the original project by using the Cross Reference Analyzer and Project Comparing Tool, ascertain the range for retesting in the usual manner by using the Cross Reference Analyzer, Project Comparing Tool, or the self-document printout, and conduct the tests.

SEE ALSO

For more information about how to check project data migrated by export or import, refer to:

"■ How to check when project data is migrated by export or import" on page E2-3

E3.4 Reusing SCS project data

This section describes the procedures of operations to perform with the SCS project in order to reuse an existing SCS project database. Do not use Windows Explorer to copy SCS projects because, if you do so, you can no longer register the SCS project in an AD project.

Duplicating an SCS project

Using AD Organizer, you can duplicate an SCS project by exporting the SCS project to be duplicated, changing the SCS name, and then importing that project. Follow these steps to duplicate an SCS project:

TIP

If the original SCS project was created by I/O list engineering with a software version earlier than R4.03.10, create a safety communication I/O list of the original SCS by using Communication I/O List Output Tool and load it into Safety Communication I/O Editor in advance.

1. Export an SCS project.
2. Import the exported SCS project. In the SCS name field of the Import SCS dialog box, enter a new name of the duplicate SCS.
3. If you are performing I/O list engineering, edit the imported safety I/O list and safety communication I/O list and check these in.
   a. You cannot check in a duplicated safety I/O list or safety communication I/O list because the P&ID Group names and P&ID Tags are the same as the original. You need to change the P&ID Tag names and P&ID Group names to separate the Group.
   b. You cannot check in the safety communication I/O list because the Program Group names are the same as the original. You need to change the Program Group names and reflect them into the signal definition and communication definition.
   However, for S2LP131, when changing the Program Group name, the corresponding communication group is automatically created. Copy the contents of the existing communication group to the created communication group, and delete the existing communication group.
   c. After making the change, you can check in the safety I/O list and safety communication I/O list by using the Check-in window.
4. Perform the following operations when engineering by using iDefine:
   a. Export the ProSafe-RS I/O file of the target SCS from AD Organizer.
   b. After the ProSafe-RS I/O file is imported in iDefine and the engineering is complete, export the created application as an iDefine-config file.
   c. Import the iDefine-config file to AD Organizer.
   d. Run the reflection process and the SCS project build process by using Generation Manager.
5. Using SCS Manager, open the SCS project that you have imported.
6. Change the following settings of the SCS project to the appropriate values.

Table E3.4-1 Settings that you need to change values

Dialog box	Tab	Setting item
Configuration Properties dialog box in Hardware Architecture View	General tab	Name
Connection Properties dialog box in Hardware Architecture View	Network Parameters tab	IP address

Continues on the next page

Table E3.4-1 Settings that you need to change values (Table continued)

Dialog box	Tab	Setting item
Resource Properties dialog box in Link Architecture View	General tab	Name, Resource number
SCS Project Properties dialog box	SCS tab	Domain number, Station number
	Project tab	CENTUM project folder
Add/Remove dependencies dialog box	-	Dependencies

TIP

When an SCS project is copied to another location, the library project will also be copied together. The SCS project at the copy destination will still reference the library at the copy source. For this reason, the dependency of the SCS project and library project will become inappropriate. It is necessary to reconfigure the path of the library project at the copy destination with the Add/Remove Dependencies dialog.

7. Save the SCS project.
8. Using Document Generator, change the title string for the cover page of the document to print.
   In the Customize dialog box that is opened from the [Option] menu of SCS Manager, clear the [Enhanced printing style] check box, change the title string, and then select the check box again.

SEE ALSO

For more information about the procedures for importing or exporting SCS project data, refer to:

E2., “Import/Export function” on page E2-1

For more information about how to use Communication I/O List Output Tool, refer to:

“■ Communication I/O List Output Tool” on page App.3-16

For more information about how to change the title string for the cover page of the document, refer to:

“● Header/Footer” in “■ Options tab” in F2.5, “Customizing print settings (backward-compatible mode)” in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about the procedure to import ProSafe-RS I/O files to iDefine, refer to:

10., "IMPORT FROM AD SUITE" in iDefine User Guide (Yokogawa Extensions) (PR12002-MAN-980_01)

■ Modifying an application

The following modifications to the application are required on the copied station.

1. Modification of inter-SCS safety communication
   Modify the inter-SCS safety communication application.
   a. The domain number and station number on the consumer and producer will change. Modify the variable names accordingly.
   b. Delete the existing binding table and regenerate it.
2. Modification of SCS link transmission
   Modify the receiving station as appropriate.

■ Checking the projects that are created by reusing data

Check that the copied SCS project is equivalent to the original project.

1. Perform build for the copied SCS project.
2. Run the Integrity Analyzer to validate the contents.

3. Launch the Cross Reference Analyzer and check that all Program Organization Units (POU) are equivalent to those of the project before the project was copied. If you are comparing with a project with a different station address, proceed to step 4.

   a. Use the Cross Reference Analyzer's function for comparison with the original project to compare the copied SCS project with the original SCS project. Check that all POUs are displayed in green, excluding the sections in which you have modified the inter-SCS safety communication and related areas. At this point, check whether the path in the title bar of Cross Reference Analyzer or in the report is correct.

   b. Validate the modified content.
   Each modification must be tested at an appropriate timing.

4. For data that cannot be checked with the Cross Reference Analyzer, use the Project Comparing Tool to ensure that the copied SCS project is equivalent to the original SCS project.

   a. Launch the Project Comparing Tool, clear the [compare imported project] check box, and compare the copied SCS project with the original SCS project. Ensure that there are no discrepancies, except in sections that you have modified. When you do so, check in the results printed from the Project Comparing Tool for the project path display area and the summary of discrepancies to make sure that the project paths that you are comparing are correct.

   b. If a discrepancy is found, check that it is appropriate.

5. Perform an offline download to the SCS and make sure that the SCS starts.

TIP

If the copied SCS project contains any modifications, except those in inter-SCS safety communication and SCS link transmission, ascertain the range for retesting in the usual manner by using Cross Reference Analyzer, Project Comparing Tool, self-document printout, or other appropriate means.

F. Installation and start-up

This chapter describes the installation of ProSafe-RS system, the wiring to field devices, a procedure of start-up including tests, commissioning and precautions for the start-up.

F1. Procedure of installation and start-up

This section describes a general procedure of the start-up of ProSafe-RS system ranging from the installation of equipment to the completion of commissioning.

Installing and getting started with ProSafe-RS

The regular procedure from the installation of equipment to the completion of commissioning is as follows.

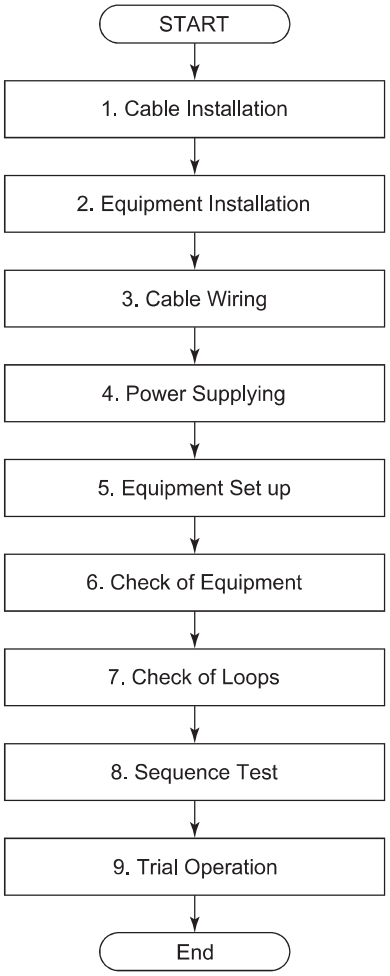

Figure F1-1 Workflow for installing and getting started with ProSafe-RS

1. Install control bus, optical cables and cables between panels.
2. Install ProSafe-RS and other equipment. When performing wireless communication with subsystems, configure the initial settings of the wireless devices on the subsystem side.
3. Wire for networks such as V net and ESB buses, as well as I/O modules and field devices.
4. Supply power to ProSafe-RS and other equipment.
5. Turn on ProSafe-RS and other equipment to start.
6. Check individual hardware of ProSafe-RS and other equipment (including I/O modules).
7. Check loops from the field to I/O modules.

8. Test application logic of ProSafe-RS.
9. Perform a trial operation for the entire system to confirm actions of the ProSafe-RS system itself.

SEE ALSO For more information about engineering of fire and gas communication, refer to:

E1.5, “Engineering for fire and gas communication” in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

Commissioning

In commissioning, procedures from No.6 “Check of Equipment” to No. 9 “Trial Operation” in the flowchart of “Installation and start-up” are performed. Confirm the following items in this series of procedures.

- All modules in SCS, wiring to field devices and wiring of power supply are correctly installed.
- All modules in SCS, field devices and power supply work without faults.
- Sensor measurement values are correct.
- Input values to SCS and output values from SCS are correct. (Including tests of high/low limits)
- Application logic works correctly according to changes of input values.
- Operations for failure occurrence take place as intended on the basis of each field device and SCS module.
- Safety application logic works correctly between actual SCSs when Inter-SCS safety communication is used.
- Confirm Demand Reaction Time.
- Confirm actions against a fault (a failure in SCS).

Precautions

- When executing offline download on a suspended SCS, confirm that the SCS is being suspended with the SCS State Management window in SENG so as not to download the database to a different SCS by mistake.
- Confirm that the SCS works normally after offline download with the SCS State Management window in SENG.
- Confirm that database is downloaded correctly with the Database Validity Check Tool in SENG.
- Set new passwords for security levels 0 and 1 after offline download.
- Precautions for LED display of CPU of SCS
  LEDs of CPU have a structure which switches between V net or Vnet/IP address display and SCS Status Display. Set LED to the SCS Status Display when SCS is in operation.
- When SDV526/L1DV526 is outputting Off signals, it takes max. 5 minutes to detect an open circuit. It takes max. 2 minutes to detect the recovery.
  Because of this, if any of the following events occur before the cause of open circuit error is eliminated after a diagnosis information message of an abnormal status caused by the open circuit is generated, a diagnosis information message of recovery is generated first. And after about 5 minutes, a diagnosis information message of an abnormal status is generated again.

TIP If you perform output enable operation before the abnormal status is re-detected, open circuit is detected about 5 minutes after a diagnosis information message of recovery is informed if the output signal is OFF. If the signal is ON, open circuit is immediately detected.

  - SDV526/L1DV526 recovers from power supply error. (The power to the I/O node or the field power supply is turned off and on.)
  - Dismounting and remounting of SDV526 or re-connection of a cable connector that was disconnected (both modules in redundant configuration.)
  - Recovery of ESB bus communication (SDV526/L1DV526 recovers from a state where it outputs fail-safe values.)

- In the case of SDV521 (style S3 or above)/L1DV521 and SDV53A (style S2 or above)/ L1DV53A, if a short circuit has occurred while the module is outputting an Off signal, it takes max. 10 seconds to detect the short circuit.
- In the case of SDV521 (style S3 or above)/L1DV521 and SDV53A (style S2 or above)/ L1DV53A, if a short circuit is detected while the module is outputting an Off signal and a diagnosis information message indicating abnormal status is generated, a diagnosis information message of recovery may be generated if either of the following events occurs before the short circuit is repaired:
  - The module is powered off and on (due to dismounting and remounting of the module or turning on and off the power to the I/O node)
  - Switch over to the standby module (when modules are in redundant configuration)

  Also note that if the module is powered on while it has a short circuit, the short circuit may not be detected. After the short circuit is repaired, it becomes possible to detect short circuits that occur afterward.
- In the case of SDV521/L1DV521 and SDV53A/L1DV53A, if a short circuit is detected while the module is outputting an On signal and a diagnosis information message indicating abnormal status is generated, a diagnosis information message of recovery may be generated before the short circuit is repaired. Even after the recovery message is generated, an Off signal is output to the channel and the channel remains in the output disabled status.

F2. Preparation before installation and start-up of N-IO nodes

You need set a node number for N-IO nodes by using the Node Number Setting Tool. When performing the I/O list engineering, you can connect the FieldMate Validator to N-IO nodes to perform connection tests between the devices and I/O modules in advance.

Preparing N-IO nodes earlier than the upper equipment

You can prepare N-IO nodes that contain N-IO I/O modules earlier than the upper equipment such as SENG, HIS, SCU.

1. Set the node numbers of all N-IO nodes.
2. Use the FieldMate Validator to perform the loop checking, to check the functionalities and to configure the field device and N-IO I/O module under the N-IO node.

F2.1 Configuring the N-IO node interface unit

For the N-IO node interface unit, you can set the node number by connecting the computer and maintenance port of the node interface unit. This section describes the tool to configure the node number.

F2.1.1 Using the Node Number Setting Tool

You can use the Node Number Setting Tool to set a node number for N-IO nodes. This section describes the Node Number Setting Tool.

Outline of the node number setting operation

Node number is not set for the N-ESB bus module that is installed in the node interface unit of the N-IO node when the module is shipped from the factory. You must set a node number for the N-ESB bus module before connecting it to the SCU.

You need to connect the computer to the maintenance port of N-ESB bus module to set the node number by using the software on the computer.

The software required to set the node number is available in the installation medium of ProSafe-RS.

Items to be prepared

The following items are required to set the node numbers:

Software medium of ProSafe-RS

It includes USB drivers and Node Number Setting Tool required to set the node number. You need to install this software on the computer that you use to set the node number.

Computer

The computer must have the following specifications:

- Hardware
  Compliant with the hardware requirement of Windows 10.
- Software
  Windows 10 Pro (64bit)

USB cable

Use the MicroUSB Micro-B connector for the N-ESB bus module side.

Preparing the computer that sets the node number

You need to install the required software on the computer that sets the node number.

Installing USB drivers

1. Insert ProSafe-RS installation medium in computer drive.
2. On the explorer, open the following folder of ProSafe-RS installation medium:
   `<ProSafe-RS software medium drive>:\ProSafe-RS\NIO_TOOLS`
3. Double click and run the `Setup.exe`.
   The User Account Control dialog box appears.
4. Click [Yes].
   A dialog box for confirming the setup details appears.
5. Select [Install] and click [OK].
   A dialog box for confirming the installation start appears.
6. Click [OK].
7. When the Windows Security dialog box appears, click [Install].
8. When the dialog box notifying the completion of installation appears, click [OK].

TIP

- When the dialog box prompting for computer restart appears, click [OK] to restart the computer.
- You can install the USB drivers after connecting the computer and N-ESB bus module.

Copying the Node Number Setting Tool

1. Insert the ProSafe-RS installation medium in the computer drive.
2. On the explorer, open the following folder of ProSafe-RS software medium:
   `<ProSafe-RS software medium drive>:\ProSafe-RS\NIO_TOOLS`
3. Copy `NodeNumSetting.exe` of the folder to any folder on the computer.

Setting node numbers

The procedure to set node numbers is as follows:

Checking before setting the node numbers

Before setting the node numbers, confirm that the status lamp of the N-ESB bus module is ON.

Remove all N-ESB bus cables and optical ESB bus cables from both N-ESB bus modules to disable the bus communication.

Removing the N-ESB bus modules

If the node numbers are already set in the N-ESB bus modules, remove one of the two N-ESB bus modules from the node interface unit. You can remove any of the two N-ESB bus modules.

If the node numbers are yet to be set (ADRS lamp is OFF), you do not need to remove the N-ESB bus module.

Connecting the computer and N-ESB bus module

With the USB cable, connect the USB port of the computer (which is used to set node numbers) and the maintenance port of the powered N-ESB bus module on the node interface unit.

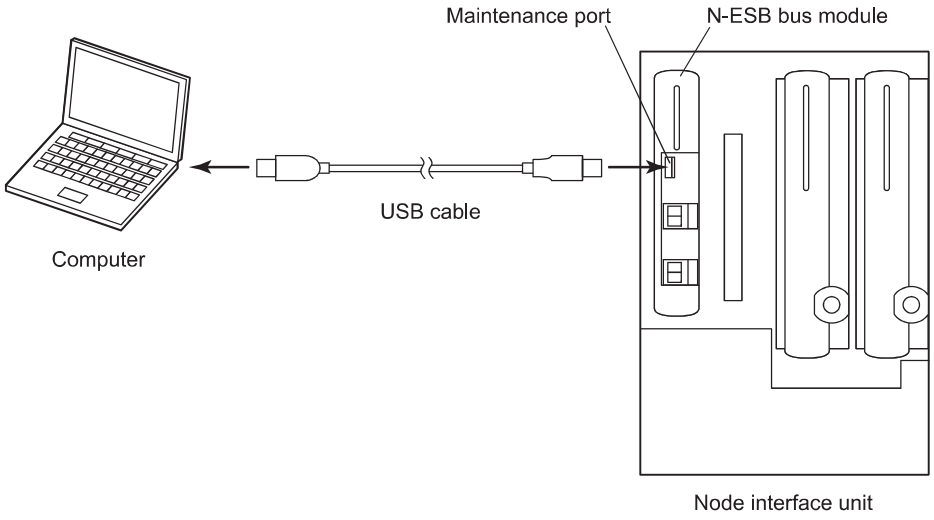

Figure F2.1.1-1 Connecting the computer and N-ESB bus module

Tool operation

1. Double click and run the `NodeNumSetting.exe` command on the computer.
   The Node Number Setting Tool window appears.

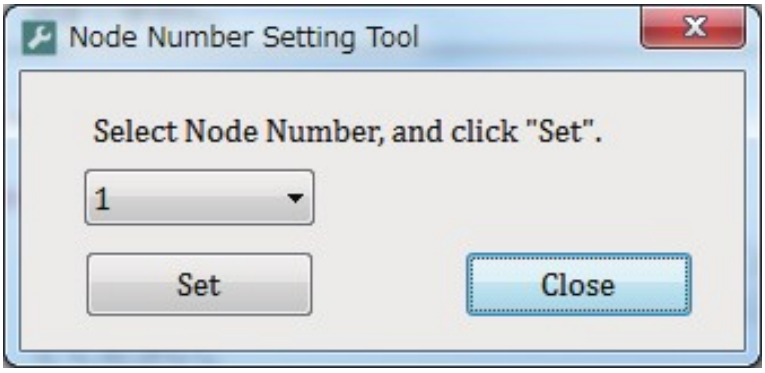

Figure F2.1.1-2 Node Number Setting Tool

2. Select a node number and click [Set].
   A confirmation dialog box appears, showing the currently set node number and node number to be set.
3. Click [Yes].
   The node number is set to the N-ESB bus module. A dialog box displaying setting completion appears.
4. Confirm the node numbers in the ADRS lamp of the N-ESB bus module.

Setting the node numbers of the other N-ESB bus module

If you removed the other N-ESB bus module, perform the following operations for the removed N-ESB bus module. If you did not remove the other N-ESB bus module, proceed to the next procedure.

1. Install the removed N-ESB bus module on the node interface unit.
   The node number is copied from the N-ESB bus module that was already installed.
2. You need to confirm the node numbers in the ADRS lamp of the N-ESB bus module.

Procedure after node number setting

1. Close the Node Number Setting Tool.
2. Remove the USB cable from the N-ESB bus module.
3. Connect all N-ESB bus cables and optical ESB bus cables to both N-ESB bus modules to enable the communication with the SCU.

TIP

The maintenance port of the N-ESB bus module is enabled when shipping. Before starting operation, you must disable the port by using the NIU maintenance port setting tool on SENG.

SEE ALSO

For more information about NIU maintenance port setting tool, refer to:

I4.5, “NIU maintenance port setting tool” on page I4-77

F2.2 Testing by using FieldMate Validator

You can use FieldMate Validator to test the N-IO modules that are defined in the safety I/O list, and import the information once again after testing. When using FieldMate Validator, you must enable the maintenance port and disable the maintenance port after use.

Outline of testing by using FieldMate Validator

Outline of testing by using FieldMate Validator is as follows:

1. Export the IOM information to be tested to FieldMate Validator.
   a. From the sub menu of the Safety I/O Editor, select [Export to FieldMate Validator] to export the data of each safety I/O list.
   b. Import the exported safety I/O list data into FieldMate Validator.

TIP

If the Field Commissioning Support Package is used, select [Export] in the submenu of the Safety I/O Editor.

2. Test the data by using FieldMate Validator.
3. Import the test results from FieldMate Validator.
   a. Export the information containing the test results from the FieldMate Validator in the safety I/O list format.
   b. From the sub menu of the Safety I/O Editor, select [Import from FieldMate Validator] to import the data exported from FieldMate Validator.

TIP

- If the Field Commissioning Support Package is used, select [Import] in the submenu of the Safety I/O Editor.
- In the Deviation setting page, select either or both [Remove Leading White-space of Import Value] and [Remove Trailing White-space of Import Value] check boxes as necessary. When importing, blank spaces in the specified location are removed.

4. Confirm that the status of test result has changed with the changes in the settings of the safety I/O list.
   When you change the IOM settings by using the Safety I/O Editor, it is indicated that that the I/O setting used for the previous test result is changed.

SEE ALSO

For more information about operating FieldMate Validator and linking with AD Suite, refer to:

manual of FieldMate Validator

For more information about operating the Field Commissioning Support Package and linking with AD Suite, refer to:

manual of Field Commissioning Support Package

F3. Overview of procedures to construct/maintain a stand-alone SCS configuration system

This section explains each of the main steps of constructing and maintaining a stand-alone SCS configuration system.

To do the following steps, you need to connect SENG to the Vnet/IP, but note that while a SENG is connected, one of the buses (bus 2) is in an error status.

- Startup of SCS
- Re-connection of SENG
- Disconnection of SENG
- Replacement of one of the redundant CPU modules.

IMPORTANT

Always connect a SENG during maintenance and make sure that you check the following before you disconnect it.

- SCS is normally started.
- SCS inputs and outputs are all normal.
- There is no diagnostic information message indicating errors of the SCS.

Getting started with SCS

The following information explains the procedure for starting SCS for the first time (offline download).

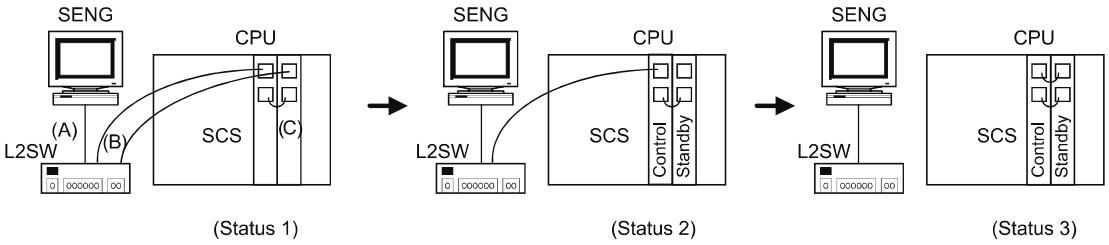

Figure F3-1 Getting started with SCS

1. Perform the following connections using network cables while the SCS is powered off. (Status 1)
   a. Connection between SENG and L2SW, and powering them on
   b. Connection of bus 1 connectors on both CPU modules to L2SW
   c. Connection between bus 2 connectors on both CPU modules
2. Turn on the power of the SCS and perform offline download from SENG.
3. After the offline download is completed, wait until one of the CPU module enters the control state and the other enters the standby state, and then remove the cable between the bus 1 connector of the standby-side CPU module and L2SW. (Status 2)

4. Disconnect the bus 1 cable of the control-side CPU module from L2SW and connect it to the bus 1 connector of the standby-side CPU module. (Status 3)

Reconnection of SENG

Use the following procedure to connect an SENG to an operating stand-alone SCS for the purpose of maintenance and so forth.

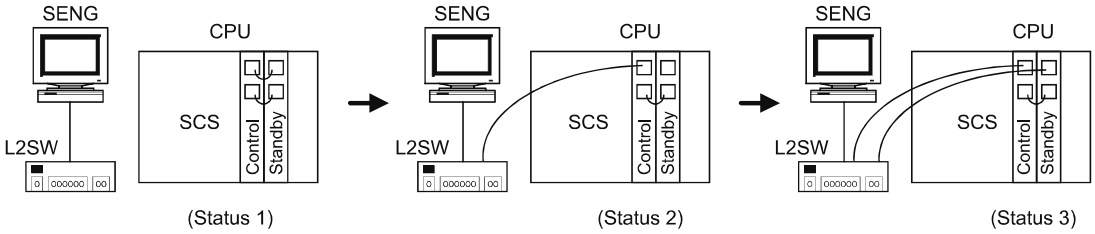

Figure F3-2 Procedure for connecting stand-alone SCS to SENG

(Status 1) above shows SCS operating in stand-alone configuration. At this timing, SENG is not powered and L2SW should be powered.

1. Disconnect the cable from the bus 1 connector of the standby-side CPU module and connect it to L2SW. (Status 2)

IMPORTANT

When you make this connection, if the cable between the bus 1 connectors of the two CPU modules of SCS is not long enough to be connected to the L2SW, you may remove the cable and use a longer cable. However, you must be very careful not to misconnect the cable.

2. Connect the bus 1 connector of the standby-side CPU module to the L2SW with a cable. Then, power on the SENG. (Status 3)

Disconnection of SENG

The SENG can be disconnected after completion of maintenance and other intended operations in the following procedure.

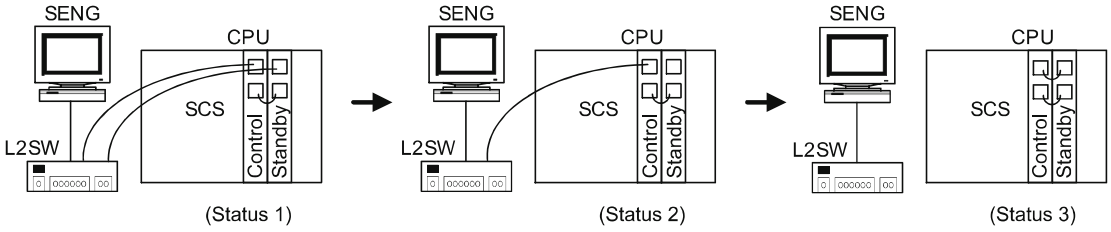

Figure F3-3 Procedure of disconnecting SENG

(Status 1) above shows a status where SCS and SENG are connected.

1. Remove the cable between the bus 1 connector of the standby-side CPU module and L2SW (Status 2) (Status 2)
2. Disconnect the bus 1 cable of the control-side CPU module from L2SW and connect it to the bus 1 connector of the standby-side CPU module (Status 3) (Status 3)

Replacement of one of the redundant CPU modules

Use the following procedure to replace one of the redundant CPU modules.

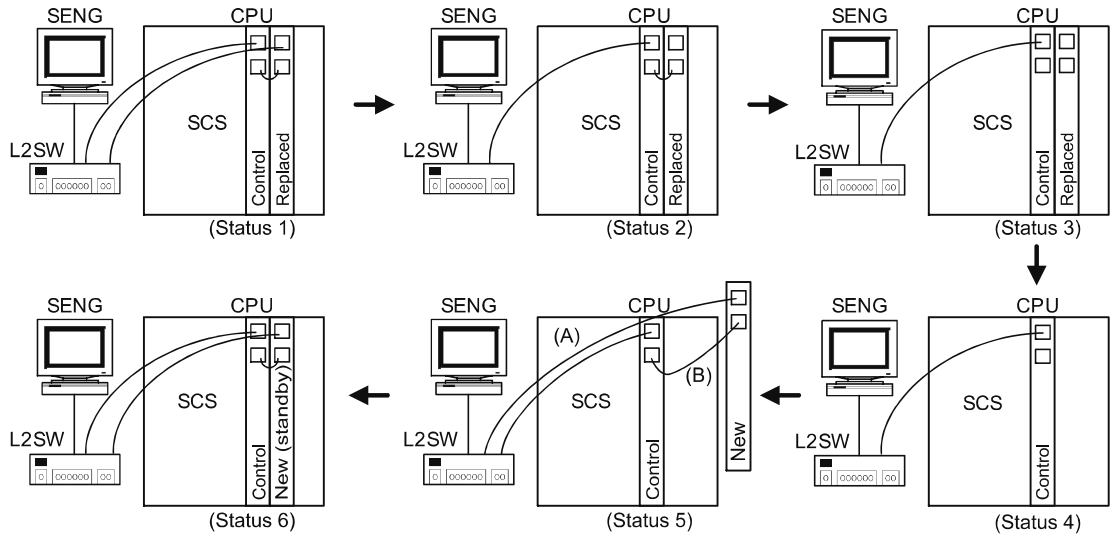

Figure F3-4 Procedure of replacing one of the redundant CPU modules

(Status 1) above shows a status where an SENG is connected for the purpose of checking diagnostic information.

1. Remove the cable between the bus 1 connector of the CPU module to be replaced (standby-side) and L2SW. (Status 2)
2. Remove the cable between the bus 2 connectors on both CPU modules. (Status 3)
3. Remove the CPU module to be replaced from the node. (Status 4)
4. Prepare a new CPU module as a replacement and perform the following connections. (Status 5)
   a. Connection between bus 1 connector of the new CPU module and L2SW
   b. Connection between bus 2 connectors on both CPU modules
5. Install a new CPU module in the node. (Status 6)

G. Emergency procedures

It is required to plan the operation procedure beforehand for emergencies including the occurrence of a shutdown demand or an equipment failure.

An emergency operation is required in case of the following. Referring to these operation flows, plan the emergency operation specifically.

G1. Operation flow during the error occurrence

This section describes the operation flow when an error occurs in the system.

Operation when SCS issues a pre-alarm because of a signal from the field

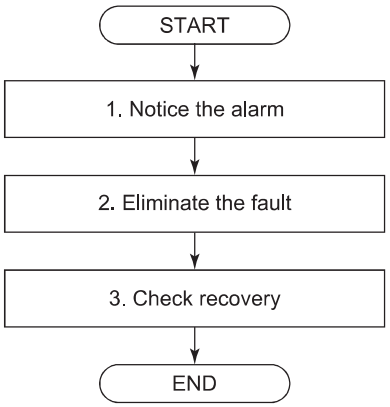

Figure G1-1 Operation when SCS issues a pre-alarm because of a signal from the field

1. Confirm the alarm with an alarm panel or HIS (for CENTUM Integration Structure).
2. Operate the DCS or field devices to eliminate the fault by following the operation manual.
3. Confirm the recovery of normal operation at the plant or DCS.

Operation when plant is shutdown because of a demand from the field

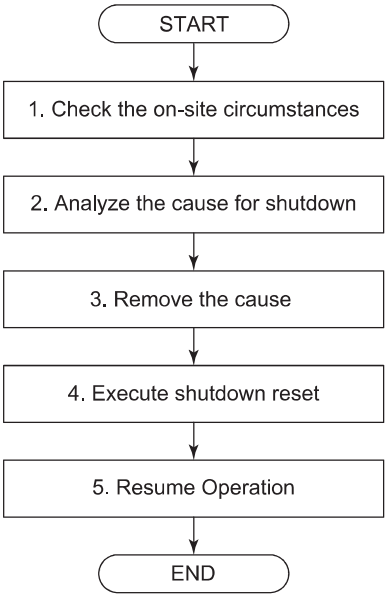

Figure G1-2 Operation when plant is shutdown because of a demand from the field

1. Maintenance personnel check the present state in the plant.

2. An engineer analyzes a cause of the shutdown with the SOE Viewer in SENG. The engineer identifies the cause of the fault with the diagnostic information message at the time when a diagnostic fault occurs and event information is displayed in the SOE Viewer. For CENTUM Integration structure, the engineer can display the process alarm message issued by SCS as a historical message on the SOE Viewer to facilitate the identification of the cause. The engineer then makes a procedure for removing the cause of the fault for recovery. The messages can also be stored as a record by outputting them to a file.
3. The maintenance personnel remove the cause of the fault according to the work procedure.
4. The maintenance personnel execute a shutdown reset operation from the ESD console.
5. Confirm the state of the plant again to restart the plant according to the operation manual.

Operation when a user manually executes a shutdown

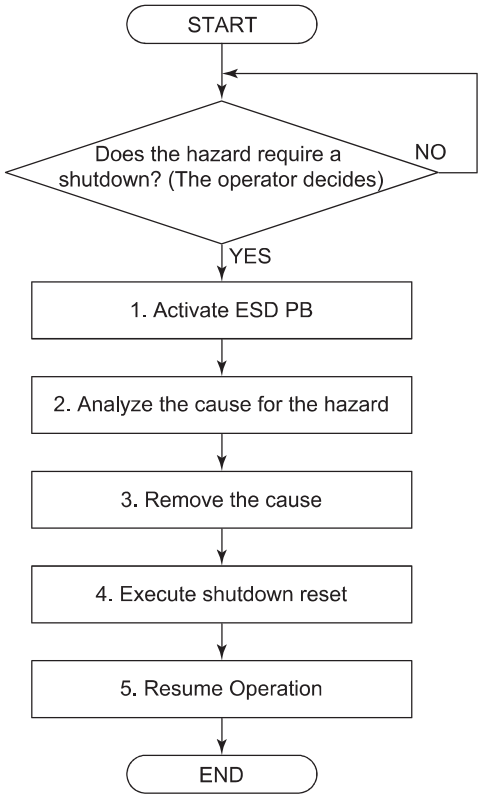

Figure G1-3 Operation when a user manually executes a shutdown

1. Maintenance personnel confirm the state in the plant and operate ESD PB (Emergency shutdown button) installed in the ESD console in order to avoid dangerous accidents.
2. The engineer analyzes the cause of the hazard with historical messages or trend data of the DCS and the SOE Viewer in SENG, and makes a work procedure for removing the cause of the fault.
3. The maintenance personnel remove the cause of the fault according to the work procedure.
4. The maintenance personnel operate a shutdown reset from the ESD console.
5. Confirm the state of the plant again to restart the plant according to the operation manual.

Operation when ProSafe-RS equipment fails

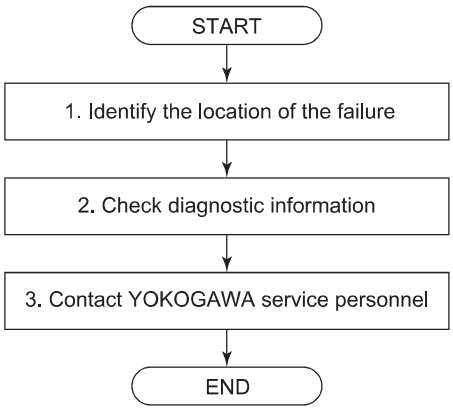

Figure G1-4 Operation when ProSafe-RS equipment fails

1. The engineer starts the SCS State Management window from SENG of the SCS where a fault occurs and confirms the present status on the display. A diagnostic information mark is displayed for I/O modules having a diagnostic fault. The engineer selects the I/O module, and display Diagnostic Information window of the I/O modules to confirm a Diagnostic Information Message related to the I/O modules.
2. The engineer confirms the messages generated by the diagnostic function of SCS. Double-click the message for the corresponding measures. This opens the Help dialog box in which the measures are indicated. Clicking a relevant message in the Diagnostic Information Window and then a [confirmation] button on the Toolbar opens the Confirmation dialog box. Diagnostic Information Messages can be confirmed by pressing the [confirmation] button on this dialog box (Operation for confirming individual messages).
3. Inform the service section at YOKOGAWA of the above information.

G2. Operations and recovery procedures during the SCS error occurrence

This chapter explains the action taken when an error occurs in the system and the recovery procedures. If an error occurs in the system, operations corresponding to the error level are performed.

There are the following three error levels.

- Fatal error
- Major error
- Minor error

TIP

In this document, I/O shutoff switches and DO shutoff switches of the universal type I/O module are referred to as an output shutoff switch.

SEE ALSO

For more information about operations at minor error occurrence and recovery procedure, refer to:

G2.3, “Actions taken at minor error occurrence and recovery procedure” on page G2-35

Overview of system operations at occurrence of fatal errors and major errors

The following provides an overview of system operations corresponding to the different SCS error levels.

Actions taken at fatal error occurrence

A fatal error disables hardware and/or software so that operation cannot be continued. Both sides of a redundant CPU module stop and all output modules output the fail-safe value.

Actions taken at major error occurrence

When a major error occurs, some hardware cannot continue the ordinary operation. When an error occurs, the system takes action which you have configured in advance for the failure of hardware. The application logics that handle major errors must also be configured.

Shutdown operations

The shutdown operations fix the output status from an SCS. There are the following three types of operations:

- Shutdown executed by a user-defined application logic
- Shutdown where the CPU fixes the output values of areas with failures
- Shutdown executed by an output module when it detects an error in the host system (CPU)

When a fatal error occurs, the CPU stops and all output modules shut down; this is called all output shutdown.

Output value at fault

The value that is output as the fail-safe value when an output module detects an error is called the Output Value at Fault. This value can be specified as an I/O Parameter for each DO or AO channel. Specify the following I/O Parameter.

Table G2-1 I/O Parameter for specifying an output value at fault

	For I/O list engineering: Safety I/O Editor of AD Suite	For RS original engineering: I/O Parameter Builder
FIO DO	Output Processing at Fault	Output Value in Detecting Error
N-IO DO	Output Processing at Fault	Output Processing at Fault (*1)
FIO AO N-IO AO	Output Processing at Fault and Output Value at Fault	Output Processing at Fault and Output Value at Fault (*1)

*1: When you use N-IO, I/O list engineering is recommended.

For AO, specify whether holding the output or outputting a fixed value in Output Processing at Fault. To output a fixed value, specify a value in Output Value at Fault.

IMPORTANT

In FIO DO, the I/O Parameter name of the setting destination is different in AD Suite and I/O Parameter Builder. The item you specified in Output Processing at Fault in AD Suite is reflected to Output Value in Detecting Error of I/O Parameter Builder when you run Reflection.

The output module does not output the "Output Value at Fault" in following status:

- The output module being initialized
- The output module with Output Shutoff switch and the switch is energized.
- The malfunctioning output channel or the output module

TIP

The descriptions in the later chapters will have the explanations regarding the tight-shut values may become the output values of the analog output modules when the Tight-Shut/Full-Open function is enabled with an I/O parameter. However, if the Tight-Shut/Full Open function is disabled, the output value of the module becomes the "default initial value upon power-on" instead of the tight-shut value.

SEE ALSO

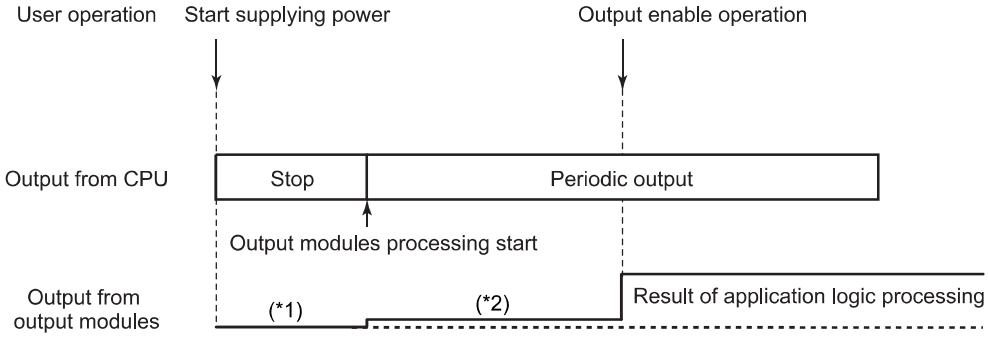
For more information about “Tight-shut/full-open” functions and “output value upon power-on”, refer to:

“■ Tight-shut/Full-open” on page App.1-27

G2.1 Actions taken at fatal error occurrence and recovery procedure

The CPU stops if a fatal error occurs in it. If the CPU module is in redundant configuration and the control right is switched to the CPU module on the standby side, the error is treated as a minor error. If the error affects the entire system, no output can be made, but in other cases, communication from the CPU is stopped; all output modules output the fail-safe value at CPU error. The fail-safe value is the value defined by the user in advance in an I/O parameter as the value output by output modules when the CPU fails.

G2.1.1 Operations and recovery procedures during the error occurrence in the entire SCS



This is an operation which is performed when electric supply is started or stopped for the entire SCS including CPU modules and I/O modules.

Actions taken at error occurrence

Regardless of the duration of a power failure, the initial start processing is performed when the power supply to the CPU nodes is renewed. Once the power is supplied to the system, I/O module startup processing is performed and the operating mode shifts to the Waiting mode. After the starting the I/O module, "0" is output from the DO channel while the tight-shut value is output from the AO channel to the field.

Recovery procedure

The user should perform the output enable operation from the SENG after confirming that all output modules have been started successfully. Once the output enable operation is performed, output values of the application logic are output to the field. When all outputs are placed in the Output Enable status, the operating mode shifts to the Running mode.

*1: “0” for DO modules, and “0.0 [mA]” for AO modules.
*2: “0” for DO modules, and the tight-shut value for AO modules

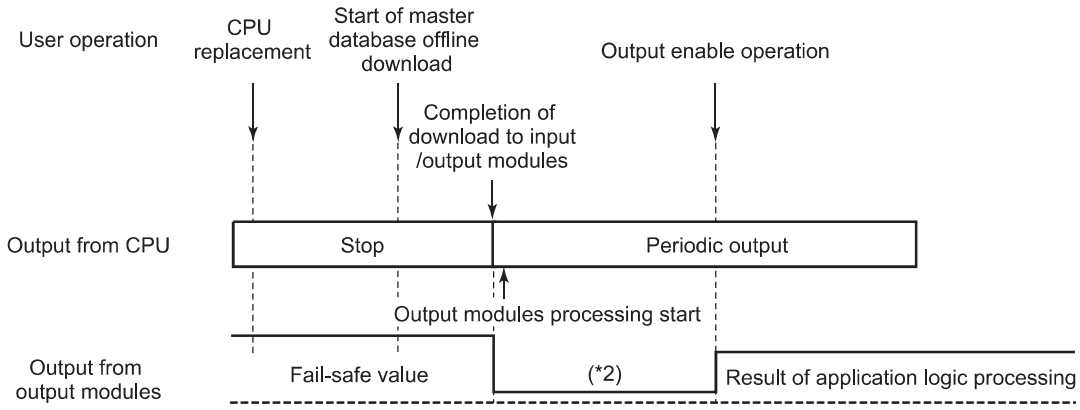
Figure G2.1.1-1 Recovery from errors affecting the entire system

G2.1.2 Actions taken at CPU module error occurrence and recovery procedure

If an error occurs in the hardware of the CPU module, CPU node or software, only the CPU stops. If the CPU module is placed in redundant configuration, it is judged that a fatal error has occurred when both CPUs fail.

The CPU also stops when offline download is performed to an operating SCS.

Actions taken at error occurrence



If the CPU does not create any data output for a certain length of time, the connected output modules will assume that the CPU is in a status where it cannot set an output value, and all output modules will output each fail-safe value specified by the user in advance. (This is called as "All output shutdown.") Input modules, on the other hand, are not affected by CPU errors. In the case of redundant CPU modules, the same operation as for a single CPU module configuration is performed if the module on the standby side fails.

Recovery procedure

In order to recover from an error occurred in the CPU module, the CPU module replacement may or may not be necessary.

Recovery procedure by replacing a failed CPU module

The following figure illustrates the output values from the SCS after the CPU module has been replaced, based on a single CPU module configuration.

*1: In the master database offline download, configuration information is downloaded to the I/O modules.
*2: "0" for DO modules, and the tight-shut value for AO modules.

Figure G2.1.2-1 Recovery after CPU module replacement

SEE ALSO For more information about the procedure for replacing the CPU module, refer to:

I1.2, "Maintenance for ProSafe-RS equipment" on page I1-9

Recovery procedure after the CPU module is restarted

Follow the recovery procedure below if the CPU module is restarted when the CPU and software are normal.

1. Fail-safe values are being output to the field from output modules. When the CPU starts up, the states of input/output modules are checked and the operating mode shifts to the Waiting mode.

2. Perform the output enable operation from the SCS Maintenance Support Tool of the SENG.
   When output modules are placed in the Output Enable status, the result of the application logic processing is output to the field. The operating mode shifts to the Running mode.

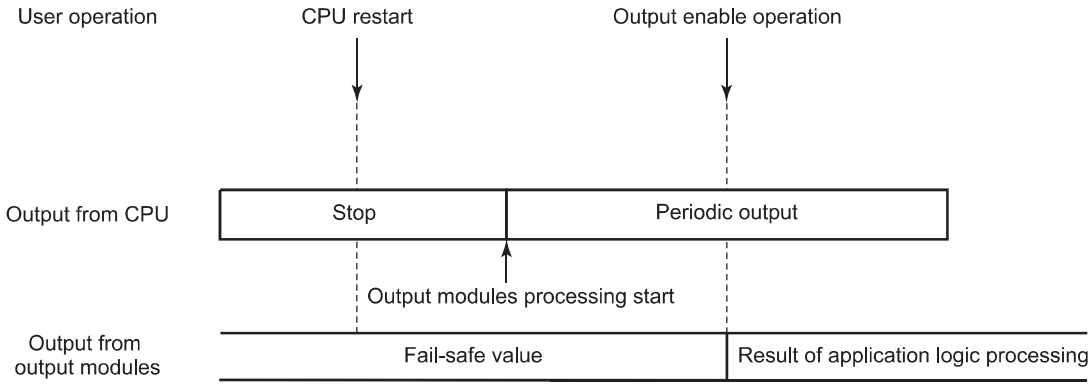


Figure G2.1.2-2 Recovery when the CPU module is restarted

Offline download

If you perform offline download to the running SCS, the CPU stops temporarily.

Also, IOM download is performed to all I/O modules.

Once an offline download is started, the output values from output modules will conform to the Figure "Recovery after CPU Module Replacement."

G2.1.3 Behavior at abnormal calculation

If there are mistakes in the application logic, intended control can no longer be performed. For the sake of safety, such mistakes must be completely removed before starting the actual operation, by thoroughly checking and testing in advance.

If there is any mistake that is left undeleted, causing overflow and other abnormal calculations during execution of the application logic, SCS stops because correct control cannot be continued. However, by making specifications with a builder, it is possible to avoid stoppage of SCS and continue the operation (*1). Diagnostic information messages are generated at occurrence of abnormal calculation and upon recovery respectively.

*1: Supported in the SCS of SCS system program R2.03 or later.

IMPORTANT

The purpose of this function is to temporarily avoid the error conditions of SCS. If an abnormal calculation occurs, review the application logic as soon as possible and modify the logic such that the abnormal calculation will not recur.

The SCS automatically recovers if the cause of abnormal calculation is removed or resolved.

Specification of behavior at abnormal calculation

Use the SCS Constants Builder to specify the behavior at abnormal calculation.
If "Continue operations" is specified, the SCS will not fail and will continue operations even if any of the following abnormal calculations occur.

- Division by zero
- Access to the outside of an array
- Overflow in floating-point calculation
- Overflow in casting

SEE ALSO For more information about how to specify the behavior upon abnormal calculation with SCS Constants Builder, refer to:

C1.2.6, “SCS Constants Builder” on page C1-21

Occurrence of division by zero

A division-by-zero calculation error occurs under the following conditions and is processed as follows.

Occurrence conditions

The denominator is zero in a division of DINT or REAL type data.

SCS processing at error occurrence

If "SCS fails" is specified in SCS Constants Builder, SCS fails.

But if "SCS continues" is specified and this error occurs, the maximum value of the applicable type (the maximum negative value if the value is negative) is assigned to the variable of the operation result. The POU (program) where the calculation error occurred does not stop but operates until the end.

Access to the outside of an array

An access to the outside of an array occurs under the following conditions and it is processed as follows.

Occurrence conditions

An index of an array variable points to the outside of the array.

SCS processing at error occurrence

If "SCS fails" is specified in SCS Constants Builder, SCS fails. But if "SCS continues" is specified and this illegal access occurs, the corresponding POU (function/function block) is stopped immediately. The POU is executed in the next and subsequent scans as well, but the execution is stopped at the same location unless the problem is resolved.

The POU (program/function/function block) that called the function/function block in which the calculation error exists is executed until the end.

SCS processing at error occurrence when SCS continues the control (details)

If you specify a value exceeding an array size for an index of an array variable in a user-defined function or user-defined function block described in the ST language, an error of accessing outside the array range occurs. The processing of the user-defined function or user-defined function block that caused the error is terminated immediately.

- The return value of the user-defined function is zero (in the case of DINT, REAL or TIME type) or FALSE (BOOL type).
- In the case of user-defined function blocks, the output parameters that were written before the occurrence of access to the outside of an array maintain the written values, and the output parameters that were not written maintain the previous values. The same rule applies to the local parameters as well.
- The values above are passed to the POU that called the user-defined function or user-defined function block where the illegal access occurred and the POU is executed until the end.

Overflow in floating-point calculation

An overflow in floating-point calculation occurs under the following conditions and is processed as follows.

Occurrence conditions

An overflow occurs in calculation between REAL type operands(*1)

*1: An overflow in integer calculation is not regarded as abnormal calculation.

SCS processing at error occurrence

If "SCS fails" is specified in SCS Constants Builder, SCS fails.

But if "SCS continues" is specified and this error occurs, the maximum value of the given type is assigned to the variable of the operation result. The maximum negative value is assigned if the first operand is negative in the case of addition/subtraction as well as if the signs of first and second operands are different in the case of multiplication/division.

The POU (program) where the calculation error occurred does not stop but operates until the end.

Overflow in casting

An overflow in casting occurs under the following conditions and is processed as follows.

Occurrence conditions

When casting REAL type data to BOOL, DINT or TIME type, the resultant value exceeds the maximum value that can be expressed by the variable.

SCS processing at error occurrence

If "SCS fails" is specified in SCS Constants Builder, SCS fails.

But if "SCS continues" is specified and this error occurs, the following values are assigned to the variables of the calculation results.

Table G2.1.3-1 Value of the variable to which the result of calculation is assigned

Variable type	Value
BOOL	TRUE
DINT	Maximum value of the DINT type (the maximum negative value if the value is negative)
TIME	Maximum value of the DINT type

The POU (program) where the calculation error occurred does not stop but operates until the end.

SCS processing at error occurrence when SCS continues the control (details)

- Casting from REAL type variable to DINT type
  When casting a value of a REAL type variable to DINT type using the ANY_TO_DINT operator, if the original value is greater than the maximum value that can be expressed by DINT type, the calculation result is replaced by the maximum DINT value (the maximum negative DINT value if the original value is negative).
- Casting from REAL type variable to TIME type variable
  When casting a value of a REAL type variable to TIME type using the ANY_TO_TIME operator, if the original value is greater than the maximum value that can be expressed as an unsigned 32-bit integer, the calculation result is replaced by the maximum value of an unsigned 32-bit integer. Although the TIME type can express up to 24 hours, truncation is not performed immediately when an overflow occurs; truncation is performed in the subsequent arithmetic calculation. (The TIME type does not take a negative value, but if a negative value is assigned in ANY_TO_TIME, the value is converted to a signed 32-bit integer once and then treated as TIME type keeping the bit sequence.)

Notification of abnormal calculation occurrence/recovery

Occurrence of abnormal calculations and recovery from them are notified via diagnostic information messages if SCS continues the control. By using the system function block (SYS_CERR), whether a calculation error has occurred or not can be handled in the application logic.

Notification of abnormal calculation occurrence

If a calculation error occurs, it is notified by the diagnostic information message (No. 4145) that indicates an occurrence of abnormal calculation. If calculation errors occur in multiple POUs (programs), a diagnostic information message is generated for each POU (program).

If different types of calculation errors occur in the same POU (program) at the same time, a diagnostic information message is generated for each type of calculation error.

● Re-notification of abnormal calculation occurrence

If the abnormal calculation status continues for a certain period of time or longer, the diagnostic information message notifying the abnormal calculation is generated repeatedly as warning. The re-warning interval is 10 minutes by default.

The re-warning interval can be changed using SYS_CERR.

● Handling of abnormal calculation status with application logic

The abnormal calculation status can be handled in the application logic by using the system function block (SYS_CERR). (*1)

*1: SYS_CERR can be used in SCS databases created by SENG of R2.03.00 or later.

● Notification of recovery from abnormal calculation

If the POU (program) that previously caused a calculation error is executed normally until the end, the calculation error of the POU (program) is regarded to have been cancelled and the diagnostic information message indicating recovery from abnormal calculation (No. 4146) is notified. The diagnostic information message indicating recovery is generated for each diagnostic information message notifying error occurrence.

■ Behavior in test functions

In logic simulation tests and SCS simulation tests, behaviors at abnormal calculation are different from those in the actual system.

SEE ALSO For more information about the behavior upon occurrence of an abnormal calculation with the test function, refer to:

"● Actions on abnormal calculation" in "■ Debug and test" in 2., "Logic simulation test operations" in Test Function Guide (IM 32P04B30-01EN)

G2.2 Actions taken at major error occurrence and recovery procedure

This section explains the operations of an SCS when a major error occurs and the recovery procedure, for the cases where errors occur in the following locations.

- Input module
- Output module
- Universal type I/O module
- Input channel
- Output channel
- Communication path between the CPU module and input/output modules
- Optical ESB bus repeater devices
- N-IO related hardware
- Safety subsystem communication paths, safety subsystem communication, and fire and gas communication modules

Notification of error status

An SCS notifies the application logic of the fact that an error occurred. It also notifies errors to the user via the SCS State Management Window of the SENG, the Status Display view of the HIS, and diagnostic information messages.

Since the following processing is performed, the user can create a shutdown application logic based on these conditions to determine desired output values for each output module.

- The status of channels belonging to the area with the failure becomes BAD.
- The status is reflected in the system function block.
- In the case of errors related to input modules and/or channels, the input value is set to the "Input value at error occurrence." The "Input value at error occurrence" is provided to the application logic instead of the actual process value if an error is detected in input module . The user must define in advance the "Input value at error occurrence" for each channel with an I/O parameter.

SEE ALSO For more information about the items to be defined as I/O parameters, refer to:

Appendix 1.3, “Settings for channel items” on page App.1-8

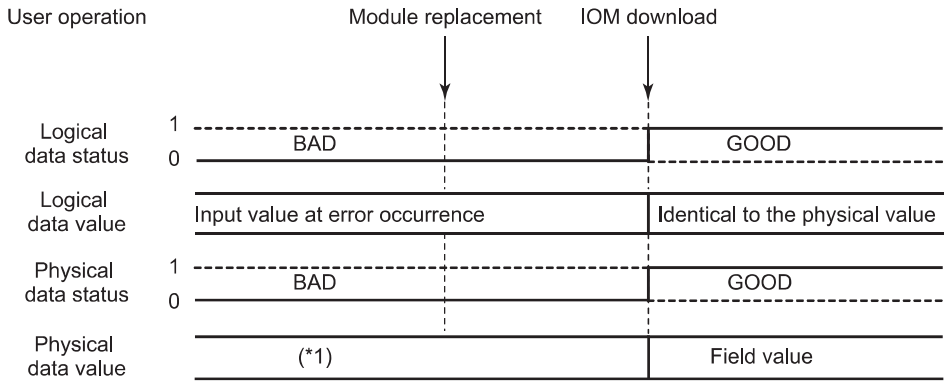
Recovery from error state

The following subsections explain the recovery measure to be taken for I/O modules when a major error occurs.

The following operations are needed to recover from an error.

- IOM download
- Output enable operation (for output modules only)

G2.2.1 Actions taken at input module error occurrence and recovery procedure



If there is a malfunction in an input module hardware, SCS treats it as an input module error. In the case of a redundant input module, the control rights switches, but the application logic continues running. This is considered as a minor error. The following explains the operations performed when an error occurs in the case of modules in single configuration or single operation status.

Actions taken at error occurrence

- CPU processing
  When an input module fails, the CPU sets the pre-defined values in the I/O parameters to all channels of the module and force the data status to BAD. The application logic should handle these changes in the inputs and statuses as errors. In order to prevent the plant from the fatal damages caused by input module failures, application logics for detecting the failures and handling the errors should be created.
- Error notification
  A module error is notified via a diagnostic information message (alarm class 1). In the SCS State Management Window on the SENG or the Status Display view on the HIS, the failed module is shown in red to indicate an error.

Recovery procedure

1. Investigate the cause of the failure based on the error code shown in the IOM Report.
2. If the input module itself is faulty, replace the module.
   If the cause of the failure is on the field side, remove the abnormality on the field side.
3. From the SCS Maintenance Support Tool of the SENG, execute IOM download.
   The CPU starts up the input module, and once the input value is acquired normally, the data status returns to GOOD.

*1: The value varies with the input module type and status.

Figure G2.2.1-1 Input module error

G2.2.2 Actions taken at input channel error occurrence and recovery procedure

An input channel error typically occurs in two cases, when there is an error on the field side or when there is a hardware failure in individual channels of an input module.

Actions taken at error occurrence

- CPU processing
  The CPU sets the input value at error occurrence, which is a value defined by the user in advance in an I/O parameter, for the faulty input channel and sets the data status to BAD.

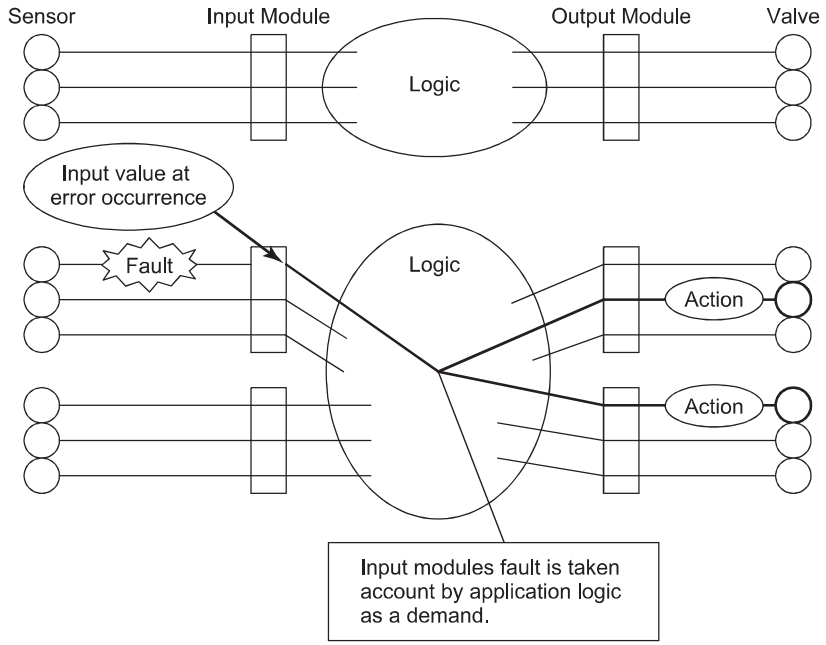


Figure G2.2.2-1 Overview of operation when an input channel error is detected

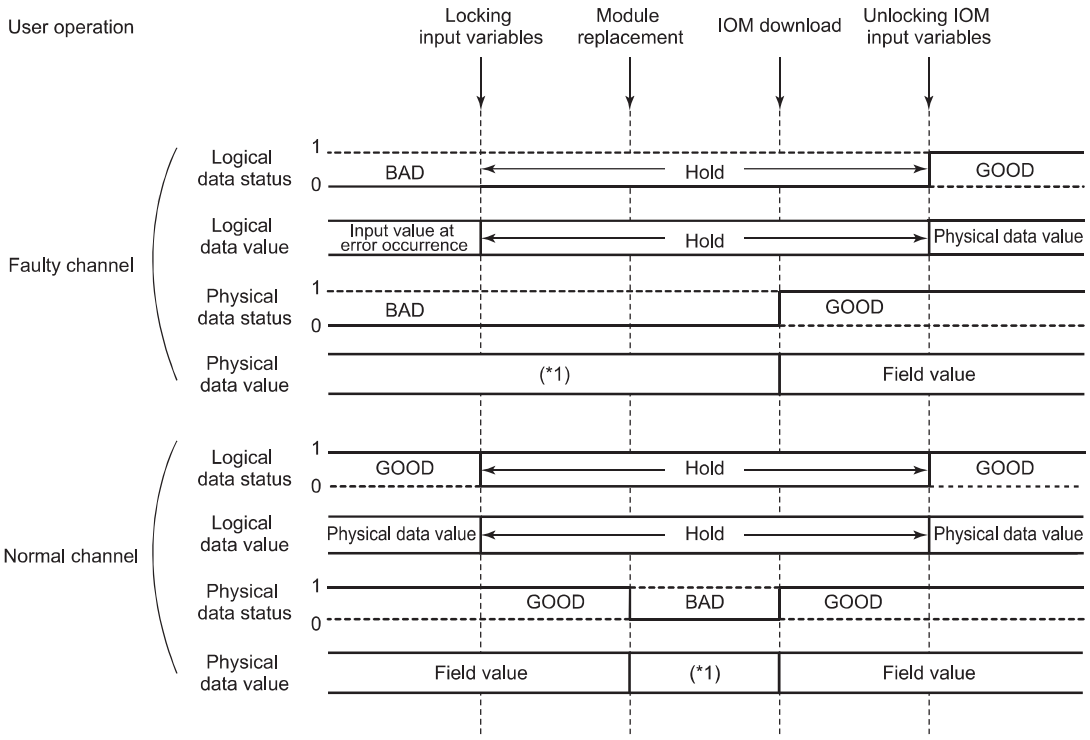
- Error notification
  A channel error is notified via a diagnostic information message (alarm class 1). However, the SCS State Management Window of the SENG and the Status Display view of the HIS display the module where channel error has occurred in the color that indicates normal.



Recovery procedure

The type of recovery procedure to be used depends on whether or not the error occurred on the module side.

Recovery procedure in the case of error on the module side

If a hardware error occurred in one or more channels of an input module, the input module needs to be replaced. The module replacing procedure for single module configuration is as follows:

1. Fix the input values sent to the application logic from the related input variables. Use the locking operation of the forcing function or maintenance override in order to fix the input variables. This minimizes the impact at module replacement.
2. After replacing the module, perform IOM download.
   The input module starts up normally.

*1: The value varies with the input module type and status.

Figure G2.2.2-2 Input module replacement (with locking operation)

SEE ALSO For more information about operations for locking input variables, refer to:

F8.8, “Windows used for forcing of I/O variables” in Engineer's Reference Manual (IM 32P04B10-01EN)

Recovery procedure in a case where the module is normal

If a failure is discovered in the field or input module connection, remove the cause of the failure. Removing the cause of the failure allows the channel with the failure status to go back to using the field value, and the data status changes to GOOD.

G2.2.3 Actions taken at output module error occurrence and recovery procedure

The result of the application logic processing is set to the logical data and physical data of the relevant output variables, and this data is then written to each channel of the corresponding output module via the I/O driver. On the other hand, the CPU acquires the status of the output module as well as the status of each channel of the output module, and sends diagnostic information messages or reflects the state information in the system function block used for channel status display. By using a system function block, module/channel statuses can be monitored via the application logic. The figure below illustrates the relationship between the CPU and output module.

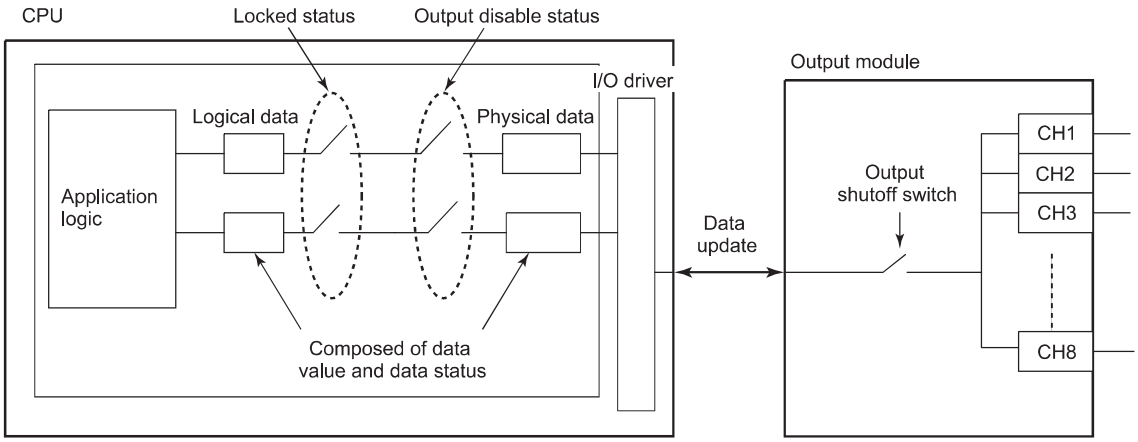


Figure G2.2.3-1 Overview of CPU and output module

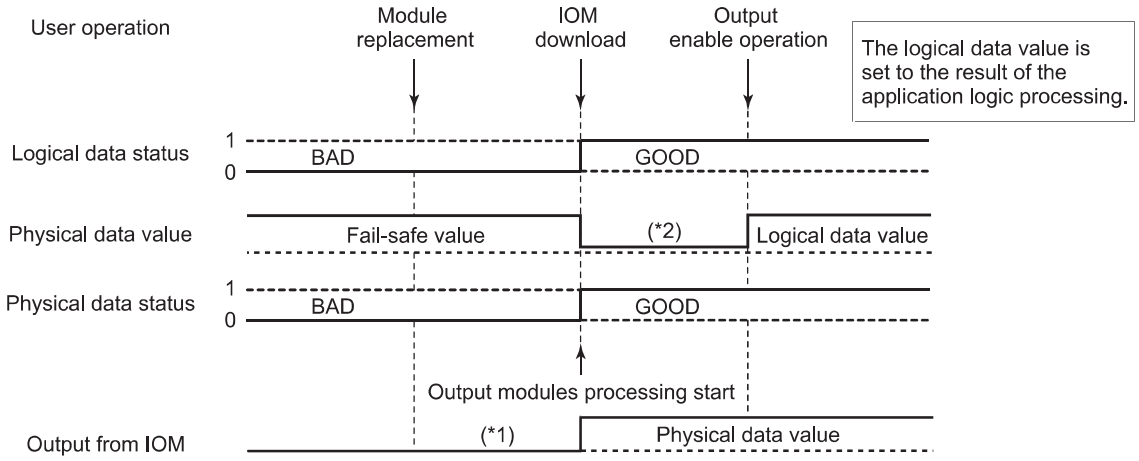
Actions taken at error occurrence

If any output module has failed, the SCS performs failure diagnosis and switches the control right and/or sends diagnostic information messages. If the control right of the duplexed modules has been switched, the actions corresponding to a minor error is taken.

If the output module was operating in the single operation mode, the following actions are taken.

- CPU processing
  The CPU sets the fail-safe value, which is predefined in an I/O parameter, to the physical data of each output channel of the faulty output module and places all the output channels in the Output Disable status. At this point, the operating mode shifts to the Waiting mode. Writing to the output module is stopped thereafter. The data statuses of all channels of the output module become BAD. The user can configure the application logic so that other associated outputs are shut down automatically based on data status changes of specific output channels to BAD.
- Error notification
  A module error is notified via a diagnostic information message (alarm class 1). In the SCS State Management Window on the SENG or the Status Display view on the HIS, the failed module is shown in red to indicate an error.



Recovery procedure

The procedure for recovery from an output module error is as follows:

1. Investigate the cause of the failure based on the error code shown in the IOM Report.
   If a system function block for output status display is used, the failure location can be checked.
2. If the output module itself is faulty, replace the module.
   If the cause of the failure is on the field side, remove the abnormality on the field side.

3. From the SCS Maintenance Support Tool of the SENG, execute IOM download.
   After the IOM download, the CPU performs startup processing of the output module. If the startup processing is completed, the output module is recognized as normal and data update starts. After the module returns to normal, "0" is output for DO modules, while the tight-shut value is output for AO modules, from all channels of the output modules.
4. Test the output module.
5. From the SCS Maintenance Support Tool of the SENG, perform the output enable operation.
   Output values of the application logic will be output. Once all output channels are placed in the Output Enable status, the operating mode shifts to the Running mode.

The figure below illustrates the flow from a failure of an output module to the recovery.

*1: “0” for DO modules, and “0.0 [mA]” for AO modules.
*2: “0” for DO modules, and the tight-shut value for AO modules.

Figure G2.2.3-2 Recovery from output module error with module replacement

G2.2.4 Actions taken at output channel error occurrence and recovery procedure

An output channel error typically occurs in two cases, when there is an error on the field side or when there is a hardware failure in individual channels of an output module. Depending on the cause of the failure, the Output Shutoff switch in the output module may be activated and an output module failure may occur, in which case the action take at error occurrence and recovery procedure may be different from those applicable to an output channel error.

To prepare for output channel failures, an application logic must be created in advance for each output channel using a function block for system status indication.

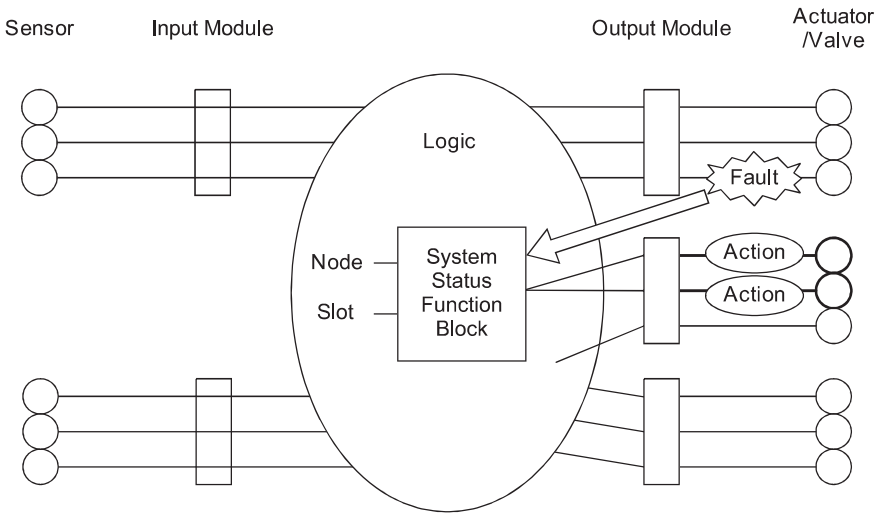


Figure G2.2.4-1 Description of logic related to output failure

SEE ALSO For more information about function blocks for system status indication, refer to:

11., “Safety system function blocks” in POU Reference Manual (IM 32P03B20-01EN)

Actions taken at error occurrence

The actions taken at error occurrence are explained for each of the following two cases: when the Output Shutoff switch is activated and when an error occurs in a single output channel without activating the Output Shutoff switch.

Channel errors accompanied by activation of the Output Shutoff switch

Even when the failure concerns only a certain output channel, the entire output module may be affected if the Output Shutoff switch in the output module is activated. In this case, "0" and "0.0 [mA]" are output from all output channels for the DO modules and AO modules, respectively.

The targets of output shutoff operation include dangerous failures (such as DO module channels are clutched to ON status) and failures where internal module protection is required (such as overcurrent of AO modules). However, the user can define in an I/O parameter whether to activate the output shutoff switch for dangerous failures where module protection is not required by the system.

The user must determine if the failure occurred in the field or in the module, based on the detailed error information provided in the Diagnostic Information window and IOM Report dialog box.

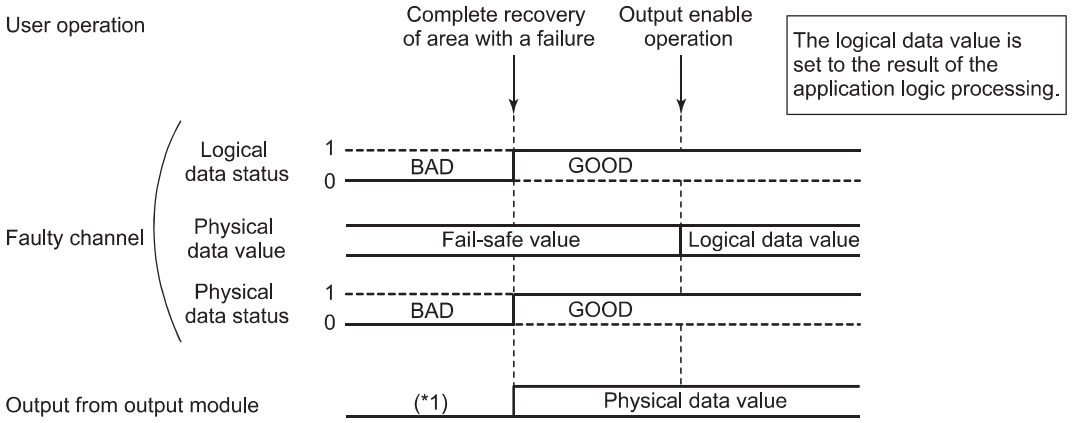
SEE ALSO For more information about IOM Report, refer to:

H3.1, “IOM Report of AIO/DIO modules” on page H3-2

Operation at occurrence of output channel errors

Errors that do not activate the Output Shutoff switch, such as disconnection on the field side, are notified as failures of individual output channels. The following operations are performed if errors occur in individual output channels.

- CPU processing
  The CPU sets the fail-safe value, which is predefined in an I/O parameter, in the physical data of the faulty output channel and places the channel in the Output Disable status. At this point, the operating mode shifts to the Waiting mode. Other normal output channels output the result of the application logic processing. The CPU continues updating the data of the output module.
- Error notification
  An output channel error is notified via a diagnostic information message (alarm class 1). The data status of the faulty output channel is set to BAD. In the SCS State Management Window on the SENG and the Status Display view on the HIS, the output module is shown in the color indicating a normal state. The status of each channel can be checked in the Diagnostic Information window of SCS Maintenance Support Tool of the SENG.



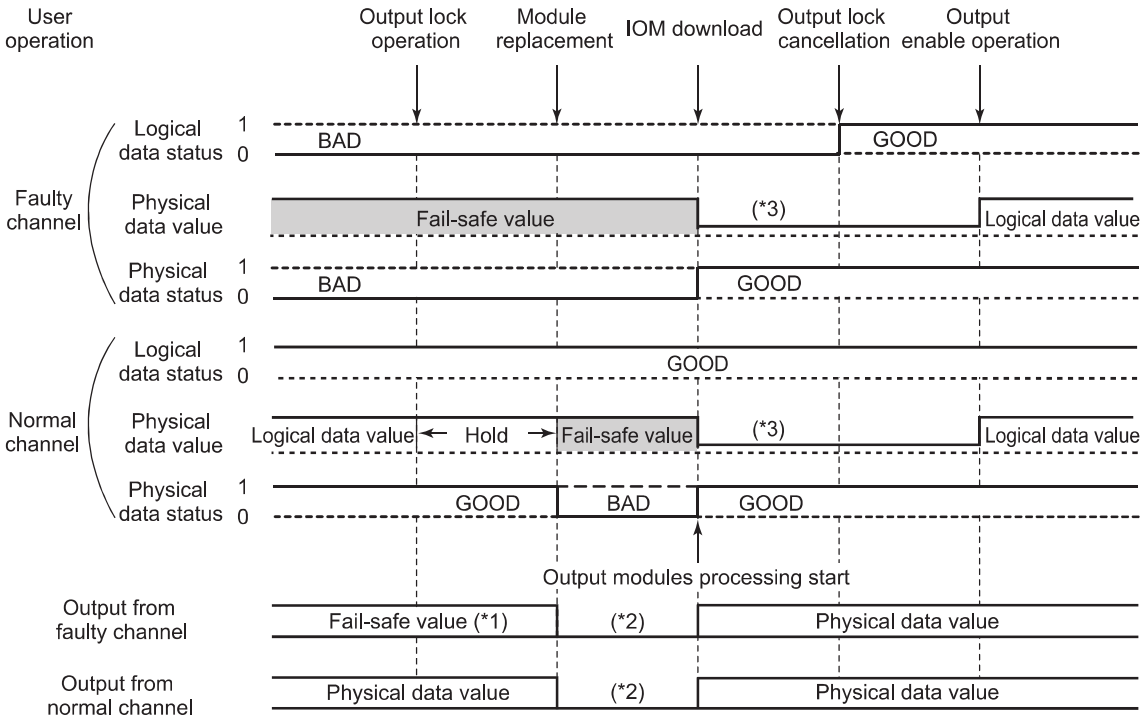
Recovery procedure

If a channel error occurred, check the following in the SCS State Management Window and IOM Report dialog box in the SCS Maintenance Support Tool to determine an appropriate recovery measure.

- Has the Output Shutoff switch been activated? Does the error concern only one channel?
- Is it a hardware failure in the module or an error on the field side?

Single channel errors (disconnection and other errors on the field side)

1. Investigate the cause of the failure and recover the field side.
   When the output module recovers, a recovery message is output and the fail-safe value, which was defined by the user in advance, is output from the relevant output channel.
2. After confirming that the output module has recovered to normal, perform the output enable operation from SCS Maintenance Support Tool of the SENG.
   Output values of the application logic will be output.



*1: “0” for DO modules, and “0.0 [mA]” for AO modules.

Figure G2.2.4-2 Recovery from channel errors

In the case of errors on a single channel (module channel hardware failure)

If any of the channels on the module side is judged to be erroneous, the output module must be replaced. The figure below illustrates the recovery procedure and the data value and data status at each timing.

*1: Fail-safe value (This value may be set to “0” for DO modules and “0.0 [mA]” for AO modules, depending on the failure condition.)
*2: “0” for DO modules, and “0.0 [mA]” for AO modules.
*3: “0” for DO modules, and the tight-shut value for AO modules.

Figure G2.2.4-3 Recovery from channel errors (with module replacement)

When the Output Shutoff switch has been activated

If the Output Shutoff switch has been activated, the following values are output from all the channels of the module.

- DO module: 0
- AO module: 0.0 [mA]

If the Output Shutoff switch has been activated, check the module status color shown in the SCS State Management Window.

- When the module status is red
  If the module status is shown in red, the possible causes of failure are as follows:
  - Hardware failure of module channels
  - Error on the field side

  See the IOM Report and identify which is the case. In both cases, the recovery measures are the same as the procedures taken after an error concerning an individual channel. Follow the recovery procedure for errors on the field side or hardware failure depending on the situation.
- When the module status is blue

If the module status is shown in blue, the output module is in the startup wait status. In this case, perform the following recovery procedure.

1. Investigate the cause of the failure and recover the field side.
2. When the recovery procedure has completed, perform the "Start output module" from the SCS Maintenance Support Tool of the SENG.

   The CPU performs the startup processing of the output module. When the output module recovers to normal status, the data status returns to normal.
3. From the SCS Maintenance Support Tool of the SENG, perform the output enable operation.
   Output values of the application logic will be output.

■ Operation and recovery procedure when overload state is detected while SDV526/L1DV526 is outputting ON signal

This section describes the operations of the module and the recovery procedure for cases where an output overload state (*1) has occurred while SDV526/L1DV526 is outputting ON signals. When SDV526/L1DV526 is in a redundant configuration, signals are output from both modules, so the operation on the detection of an overload state and the recovery procedure are described separately for the active module and standby module.

The operation in a non-redundant configuration is the same as the active module in a redundant configuration.

*1: An overload state occurs when the connected field device has a fault that causes a short circuit or overcurrent when the output from the module is set to ON.

● Behavior of SCS and recovery procedure when the active module in redundant configuration or module in non-redundant configuration has failed

- Behavior
  - If an overload state is detected only in the active module of redundant configuration, the control right is transferred to the standby module and the operation continues. (*1)If an overload state is detected on both modules, the standby module goes to IOM Fail and the control right is not transferred.
  - The module sets the output signal of the error channel to OFF, and the channel goes to an Output Disable status.
  - The channel is released from the error but it remains in the Output Disable status.

  *1: In this case, recover the error module that has become a standby module by carrying out the recovery procedure for a standby module.
- Recovery procedure
  1. Clear the cause of overload state to recover the field device.
  2. Use the SCS maintenance support tool on SENG and perform the output enable operation.
     This allows the output value of the application logic to be output.

Behavior of SCS and recovery procedure when the standby module in redundant configuration has failed

- Behavior
  - The output shutoff switch is activated and the standby module goes to IOM Fail.
  - In the SCS State Management Window of the SCS maintenance support tool, the module's status is shown in blue (startup wait status).
- Recovery procedure
  1. Clear the cause of overload state to recover the field device.
  2. Use the SCS maintenance support tool on SENG and perform the output module startup operation.
     The module starts up and operates as a standby module.

Behavior of SDV521/L1DV521 or SDV53A/L1DV53A and recovery procedure when a short circuit is detected

This section describes the behavior of the SDV521/L1DV521 or SDV53A/L1DV53A module and the recovery procedure for cases where a short circuit has occurred in the field wiring of the module.

- Behavior
  - The module sets the output signal of the error channel to OFF, and the channel goes to an Output Disable status.
  - The channel may be released from the error but it remains in the Output Disable status.
- Recovery procedure
  1. Clear the cause of short circuit to recover the wiring on the field side.
  2. Use the SCS maintenance support tool on SENG and perform the output enable operation.

     This allows the output value of the application logic to be output.

G2.2.5 Operations and recovery procedures during the error occurrence in the universal type I/O module

If there is a malfunction in the hardware of I/O module, an error occurs in universal type I/O module. If the I/O module is redundant, the control rights are switched, and the application logic continues running. This is considered as a minor error. The following explains the operations performed when an error occurs during the single configuration or single operation.

Operations during error occurrence in the I/O module

Operations during the error occurrence in the I/O module differ depending on the set channel type.

If the channel of the I/O module is set to input, operations are similar to when an error occurs in the input module.

If the channel of the I/O module is set to output, operations are similar to when an error occurs in the output module.

I/O module recovery procedures

Recovery procedures for the I/O module differ depending on the set channel type.

If the channel of the I/O module is set to input, recovery operations are similar to when an error occurs in the input module.

If the channel of the I/O module is set to output, recovery operations are similar to when an error occurs in the output module.

SEE ALSO For more information about operations at input module error occurrence and recovery procedure, refer to:

G2.2.1, “Actions taken at input module error occurrence and recovery procedure” on page G2-12

For more information about operations at output module error occurrence and recovery procedure, refer to:

G2.2.3, “Actions taken at output module error occurrence and recovery procedure” on page G2-15

Operations at input channel error occurrence and recovery procedure

Operations and recovery procedures during input channel error occurrence in the universal type I/O module are the same as those for input channel error occurrence in an input module.

SEE ALSO For more information about operations at input channel error occurrence and recovery procedure, refer to:

G2.2.2, “Actions taken at input channel error occurrence and recovery procedure” on page G2-13

Operations at output channel error occurrence and recovery procedure

This section describes the operations and recovery procedures when an output channel of the universal type I/O module has failed under the following conditions:

- When the Output Shutoff switch is activated
- When an output channel fails without activating the Output Shutoff switch

Output shutoff switch of the universal type I/O module

The output shutoff switch in the universal type I/O module is different depending on the set channel signal type.

- DO channel : DO shutoff switch
- AO channel: I/O shutoff switch

The following shows the channel operations when a DO shutoff switch and I/O shutoff switch have been activated.

- When DO shutoff switch is activated due to malfunction detection by DO channel:
  An error occurs with all DO channels in the universal type I/O module and the output of the corresponding channels are shut off.
- When an I/O shutoff switch has been activated upon detection of a failure by the AO channel
  An error occurs with all AI (2-wire), AO, DI, and DO channels in the universal type I/O module and the input and output of the corresponding channels are shut off.

Channel errors during output shutoff switch operation

When DO shutoff switch in the universal type I/O module is activated during the error occurrence, the output of all DO channels in the I/O module becomes 0, even if the error occurs only in a certain output channel.

Similarly, when an internal I/O shutoff switch in the universal type I/O module is activated, the outputs of all AO channels in the I/O module become 0.0 [mA] and the output of the DO channel becomes 0. If the universal type I/O module has an input, the inputs of all AI (2-wire) channels and DI channels in the I/O module become the input value at error occurrence.

At this time, the system alarm of channel error is sent for the channels that are shut off.

The output shutoff is activated for dangerous failures, such as DO module channels are stuck in the ON status, and failures where internal module protection is required, such as overcurrent of AO modules. However, the user can define in an I/O parameter whether to activate the output shutoff switch for dangerous failures where module protection is not required by the system.

The user must determine if the failure occurred in the field or in the module, based on the detailed error information that is provided in the Diagnostic Information window and IOM Report error.

Operation at occurrence of output channel errors

Operations and recovery procedures during output channel error occurrence in the universal type I/O module are the same as those for output channel error occurrence in an output module.

SEE ALSO For more information about operations at error occurrence on an individual output channel and recovery procedure, refer to:

G2.2.4, “Actions taken at output channel error occurrence and recovery procedure” on page G2-17

G2.2.6 Actions taken at errors between CPU and Input/ Output module and recovery procedure

Errors between the CPU and input/output module refer to errors on both sides of the SB bus and errors on both sides of the communication module of a node.

The value output from output channels when a system error is detected must be specified in advance as a fail-safe value in an I/O parameter.

SEE ALSO For more information about behavior upon occurrence of an error when using an optical ESB bus repeater, refer to:

G2.2.7, “Actions taken at error occurrence for optical ESB bus repeater devices” on page G2-26

Actions taken at error occurrence

If a node error or bus error occurs, both the CPU and input/output module perform actions taken at error occurrence, respectively.

CPU processing

- The input value at error occurrence is set for input variables corresponding to all the input channels that do not respond.
- The fail-safe value is set for the physical data of output variables corresponding to all the output channels that do not respond, and they are placed in the Output Disable status.
- The input value at error occurrence set for the input variables and the fail-safe value set for the output variables are specified in I/O parameters.
- The CPU stops updating data of the relevant output module.

SEE ALSO For more information about the items to be defined as I/O parameters, refer to:

Appendix 1.3, “Settings for channel items” on page App.1-8

Error notification

- A channel error is notified via a diagnostic information message (alarm class 1). The data status of all the channels is set to BAD.
- When a node encounters an error, a diagnostic information message regarding the node error will be generated. When the node returns to normal, a diagnostic information message (alarm class 1) is notified to indicate recovery from the I/O module error.

Recovery procedure

In order to make an output of an output module recover after handling a hardware failure, it is necessary to perform the output enable operation from SCS Maintenance Support Tool of the SENG.

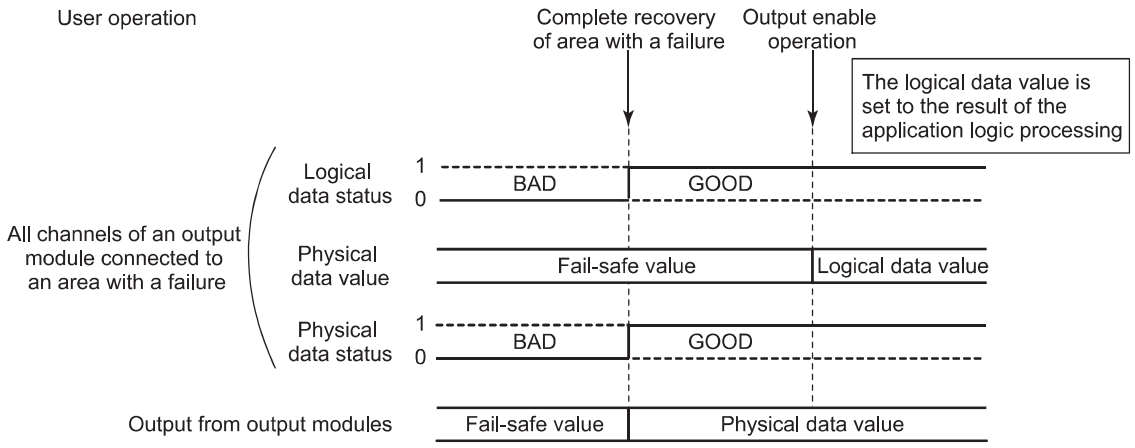

Figure G2.2.6-1 Output module recovery from communication path errors

TIP

Input modules resume using input values from the field and their data status becomes GOOD once the cause of failure is removed.

G2.2.7 Actions taken at error occurrence for optical ESB bus repeater devices

This section explains the actions taken at error occurrence to the following optical ESB bus repeater devices.

Devices for SCS that supports SIL 3

- SNT401/SNT411 and SNT501/SNT511 (Optical ESB bus repeater modules)
- SNT10D (Unit for optical bus repeater module)

Devices for SCS that supports SIL 2

- L1NT401/L1NT411 and L1NT501/L1NT511 (Optical ESB bus repeater modules)
- L1NT10D (Unit for optical bus repeater module)

The model names of devices for SCS that supports SIL 3 are used in the explanation. Model names in brackets indicate devices for SCS that supports SIL 2.

Actions taken at errors of optical ESB bus repeater/fiber-optic cable

The actions to be taken for a failure of optical ESB bus repeater module or abnormality of fiber-optic cable is the same as the actions taken at an ESB bus error.

- In the event of a failure in one of the optical ESB bus repeater modules in a redundant configuration, or disconnection or other abnormality in any fiber-optic cable connecting these modules, a "diagnostic information message indicating the SSB401 (L1SB401) error (Message No. 0065)" is notified as the event of the I/O node connected via the applicable failure location.
  Example:

  0065 SCS0101 SBS Fail FIO NODE 02 SBS RIGHT

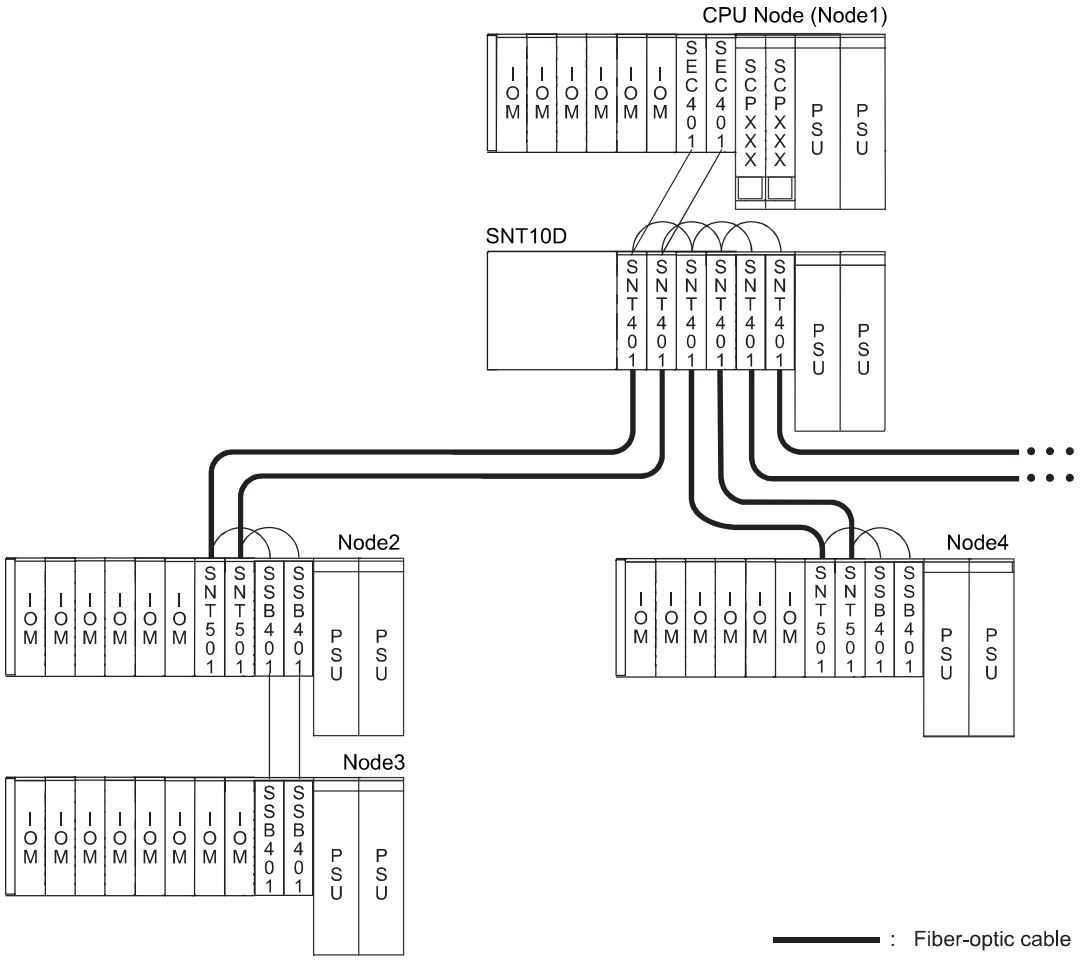

Figure G2.2.7-1 Connection example of devices for SCS that supports SIL 3

The actions taken at errors of optical ESB bus repeater modules is explained using the above figure showing a connection example.

Nodes 2 and 3 are accessed via SNT401 and SNT501 (L1NT401 and L1NT501) modules. Therefore, a failure in the SNT401 or SNT501 (L1NT401 or L1NT501) module that is relaying Node 2 or 3 disables communication with Nodes 2 and 3.

- A diagnostic information message indicating an SSB401 (L1SB401) error (Message No. 0065) is notified for Nodes 2 and 3 in either of the following cases:
  - In the SNT10D (L1NT10D) shown in the figure, one of the SNT401 (L1NT401) modules connecting Nodes 2 and 3 fails.
  - One of the SNT501 (L1NT501) modules installed in Node 2 fails.
- If both of the SNT401 (L1NT401) modules or both of the SNT501 (L1NT501) modules fail, a node error occurs in each I/O node connected via the failed optical ESB bus repeater modules. If both of the SNT501 (L1NT501) modules installed in Node 2 fail, Nodes 2 and 3 connected via the SNT501 (L1NT501) modules generate an error. Similarly if both of the SNT401 (L1NT401) modules installed in the SNT10D (L1NT10D) fail, Nodes 2 and 3 also generate an error.

TIP

A diagnostic information message indicating an ESB bus error (Message No. 0063) is issued only when an error occurs in all I/O nodes excluding the CPU node. In a configuration where optical ESB bus repeater modules are used to provide multiple ESB bus lines, this diagnostic information message (Message No. 0063) is not issued in the event of an error in only one line.
For example, assume a system configuration that partially uses optical ESB bus repeater modules. Even if errors are occurred in bus 1 of all I/O nodes those are connected to the ESB bus but are not connected to fiber-optics, the aforementioned diagnostic information message indicating an ESB bus error (Message No. 0063) is not issued.

The same rule applies when the SEC402 (L1EC402) is used to connect nodes to both the upper and lower sides. For example, the diagnostic information message No. 0063 is not notified if errors occurred in only one side of the duplicated buses of all I/O nodes connected via the upper connector.

Actions taken at errors of node power supply

Installing optical ESB bus repeater modules in a unit for optical bus repeater module

If optical ESB bus repeater modules are installed in SNT10D (L1NT10D), which is a unit for optical bus repeater module, set the hardware setting switch [1] (installation unit setting DIP switch 1) on the optical ESB bus repeater modules to "0: Installation in unit for optical bus repeater module." When the switch is set this way, an error in one of the SNT10D (L1NT10D) power-supply modules will be notified as a failure of the I/O nodes connected via the optical ESB bus repeater modules.

- If an error occurs in one of the power-supply modules of the SNT10D (L1NT10D) in which the optical ESB bus repeater modules are installed, the optical ESB bus repeater modules of the corresponding side stop communicating. If the error occurred in the left power-supply module, the optical ESB bus repeater modules installed in odd-number slots stop communication. If the error occurred in the right power-supply module, the optical ESB bus repeater modules installed in even-number slots stop communication. Communication has stopped from the optical ESB bus repeater module on one side, so "diagnostic information messages indicating the SSB401 (L1SB401) error (Message No. 0065)" for all I/O nodes connected via the applicable optical ESB bus repeater modules are notified.
- In the event of errors in both of the power-supply modules of the SNT10D (L1NT10D) in which the optical ESB bus repeater modules are installed, the errors are notified to all I/O nodes connected via the optical ESB bus repeater modules installed in the applicable SNT10D (L1NT10D).

Installing optical ESB bus repeater modules in a CPU node or I/O node

If optical ESB bus repeater modules are installed in a CPU or I/O node, set hardware setting switch [1] (installation unit setting DIP switch 1) to "1: Installation in node (safety control unit or safety node unit)."

- If SW [1] is set to "1," the optical ESB bus repeater modules will continue to operate without being affected, even if an error occurs in one of the power-supply modules of the node in which the optical ESB bus repeater modules are installed.
- In the event of an error in both of the power supply modules of the node in which the optical ESB bus repeater modules are installed, an error occurs in this node and all I/O nodes connected via the applicable optical ESB bus repeater modules.

IMPORTANT

- When installing optical ESB bus repeater modules in a SNT10D (L1NT10D), set the installation unit setting DIP switch 1 to "0." If this switch is set to "1," a failure of the I/O nodes connected via the optical ESB bus repeater modules is not notified when one of the power-supply modules of the SNT10D (L1NT10D) is in error status.
- When installing optical ESB bus repeater modules in a CPU or I/O node, set the installation unit setting DIP switch 1 to "1." If this switch is set to "0," an error occurring in one of the power-supply modules of the CPU or I/O node will be recognized as an error in the optical ESB bus repeater modules on one side.

G2.2.8 Operations during hardware error occurrence related to N-IO

This section describes the operations when hardware errors related to N-IO occur. It also explains the recovery monitoring operation for the point where the malfunction occurred.

N-ESB bus

- Error detection
  The SCS performs N-ESB bus diagnosis when accessing the I/O module of the N-IO node. If one side of N-ESB bus is faulty, it is considered as minor error. If both the sides of N-ESB buses are faulty, it is considered as major error, and all N-IO nodes that are connected to the corresponding N-ESB bus are considered as errors.
- Recovery monitoring
  The SCS monitors the recovery status of N-ESB bus periodically. When the bus has recovered, the N-ESB bus status in the SCS returns to normal. Then, the SCS switches over both buses alternately while communicating with NIU.

N-IO node

- Error detection
  The SCS monitors the status of N-ESB bus module periodically. If one side of N-ESB bus module is faulty, it is considered as minor error If both the sides of N-ESB bus module are faulty, the corresponding N-IO node and all N-IO nodes under it are considered as major errors. The bus types that connect the subordinate N-IO nodes, irrespective of whether they are N-ESB bus or optical ESB bus, are considered as major errors.

  The following figure shows the effective range of the N-IO node when it is abnormal.

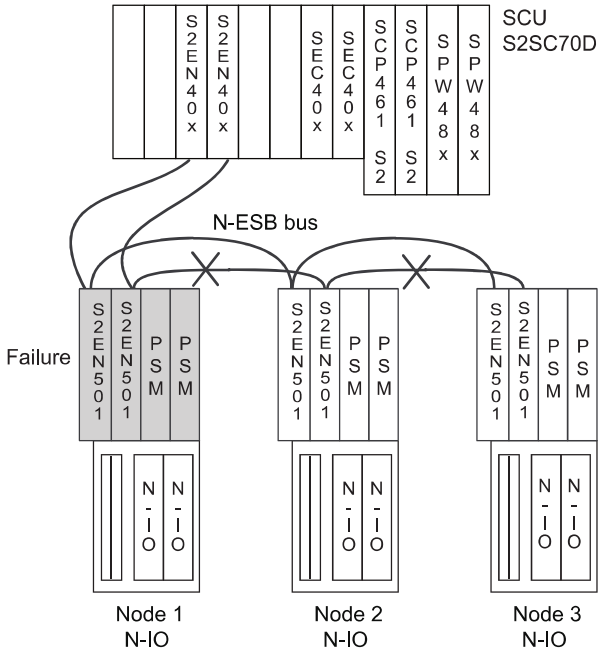

Figure G2.2.8-1 Effective range of the abnormal N-IO node

Node2 and Node3 communicate with the SCS through S2EN501 of Node1. If S2EN501 of Node1 that communicate with the SCS is faulty at both sides or has power failure, the communication to all I/O module of Node 2 and Node 3 is disabled.

- Recovery monitoring
  The SCS periodically monitors the recovery of abnormal N-IO node. When the N-IO node has recovered, the N-IO node status in the SCS returns to normal.

Power supply module of the N-IO node

- Error detection
  The SCS monitors the status of the power supply module of the N-IO node periodically. If the power supply module is faulty at one side, the N-IO node is considered to have a minor error. If the power supply module is faulty at both sides, the N-IO node is considered to have a major error.
- Recovery monitoring
  The SCS monitors the recovery of the power supply module of the abnormal N-IO node periodically. When the module has recovered, the power supply module status in the SCS returns to normal.

F-SB bus

- Error detection
  The SCS performs diagnosis of the F-SB bus between NIU and I/O unit when accessing the I/O module of the N-IO node. If one side of F-SB bus is faulty, it is considered as minor error. If both sides of F-SB bus are faulty, the I/O modules of the corresponding NIU becomes error, and it is considered as a major error.
- Recovery monitoring
  The SCS monitors the recovery status of F-SB bus periodically. When the bus has recovered, the F-SB bus status in the SCS returns to normal. Then, NIU communicates with the I/O module by using both buses simultaneously.

G2.2.9 Operations at fire and gas communication error occurrence and recovery procedure

This section explains the operations upon occurrence of an S2LP131, fire and gas device, or fire and gas communication error and recovery procedure therefor.

The CPU sets the communication data to the value upon error specified by the user and changes the data status to BAD with the timing described below. The timing of status change will vary between data used with safety communication and data used with interference-free functions.

- Data used with safety communication
  The timing at which the Safety Layer of the SCS uses the Safety Measure of PROFIsafe and detects an error
- Data used with interference-free functions
  The timing at which the S2LP131 uses the communication status of PROFINET and detects an error of the communication path

Operations at error occurrence along path between the CPU and S2LP131 and recovery procedure

Errors along the path between the CPU and S2LP131 are errors of the FIO node and errors on both sides of the SB bus and ESB bus from the CPU to the S2LP131. This sections explains the operations at error occurrence and recovery procedures therefor.

Operation at error occurrence

- CPU processing
  The CPU sets values specified in advance as I/O Parameters by the user to all communication data in the range of the error. The user can specify in advance whether to use the value immediately before the error is detected or to use the preset “input value at error occurrence.”
- Error notification
  The CPU notifies a message containing diagnosis information for the FIO node error. In addition, an IOM error and recovery diagnosis message is notified upon recovery. The CPU sets the data status of all communication data in the range of the failure to BAD while the error is occurring.

  In the SCS State Management window of SENG or the Status Display view of HIS, the location of the error is shown in red. This will switch to green upon recovery from the error.

Recovery procedures

Remove the cause of the error. After removing the cause of the error, you do not need to perform output enable operation from SENG.

Operations at S2LP131 error occurrence and recovery procedure

S2LP131 errors are hardware failures, communication board errors, disconnection from the node, and configuration errors.

Operation at error occurrence

- CPU processing
  The CPU sets values specified in advance as I/O Parameters by the user to all communication data obtained via the S2LP131. The user can specify in advance whether to use the value immediately before the error is detected or to use the preset “input value at error occurrence.”

- Error notification
  The CPU notifies a message containing diagnosis information for the IOM error. The CPU sets the data status of all communication data obtained via the S2LP131 to BAD while the error is occurring.

  In the SCS State Management window of SENG or the Status Display view of HIS, the S2LP131 is shown in red. This will switch to green upon recovery from the error.

Recovery procedures

Remove the cause of the error. After removing the cause of the error, you do not need to perform output enable operation from SENG.

Operations at error occurrence along path between the S2LP131 and fire and gas devices and recovery procedure

Errors along path between the S2LP131 and fire and gas devices are S2LP131 port errors, YFGW410 failures, path errors between S2LP131 and YFGW410, and path errors between YFGW410 and GS01.

SEE ALSO For more information about operations at safety communication error occurrence and recovery procedure, refer to:

"■ Operations at error occurrence regarding safety communication between the CPU and fire and gas devices and recovery procedure" on page G2-33

Operation at error occurrence

- CPU processing
  The CPU sets values specified in advance as I/O Parameters by the user to data used with interference-free functions in the range of the error. The user can specify in advance whether to use the value immediately before the error is detected or to use the preset "input value at error occurrence."
- Error notification
  The CPU notifies a message containing diagnosis information indicating a communication error of the S2LP131. The CPU sets the data status of the data used with interference-free functions in the range of the error to BAD while the error is occurring.

  In the SCS node status display dialog box of HIS, "1C" is shown in red. The display will disappear upon recovery from the error.

Recovery procedures

Remove the cause of the error. After removing the cause of the error, you do not need to perform output enable operation from SENG.

Operations at error occurrence regarding safety communication between the CPU and fire and gas devices and recovery procedure

Errors regarding safety communication are CRC errors between the CPU and fire and gas devices and errors such as timeouts.

Operation at error occurrence

- CPU processing
  The CPU sets values specified in advance as I/O Parameters by the user to data used with safety communication in the range of the error. The user can specify in advance whether to use the value immediately before the error is detected or to use the preset "input value at error occurrence."
- Error notification

The CPU notifies a message containing diagnosis information for the fire and gas communication error. The CPU sets the data status of the data used with safety communication of fire and gas devices to BAD while the error is occurring.

In the SCS node status display dialog box of HIS, "1C" is shown in red. The display will disappear upon recovery from the error.

Recovery procedures

Remove the cause of the error. After removing the cause of the error, you do not need to perform output enable operation from SENG.

G2.3 Actions taken at minor error occurrence and recovery procedure

A minor error does not affect the application logic execution function itself. For example, "one-side" failure of a redundant hardware applies to this.

When an error occurs in a device that has been configured for dual redundancy, the control rights get transferred to the device on standby so processing can continue. Such errors are regarded as minor. After switching the control right, the same operation as for single configuration system is performed. The fact that the control right is switched due to a failure is notified via a diagnostic information message. Since the SCS can continue controlling in this case, the data status is not changed nor is any error status notification to system function blocks performed. Confirm that the failed hardware is switched to standby side and then replace the failed hardware.

IMPORTANT

Observe the following precautions when one of the redundant pair of I/O modules has failed and you must fix it:

- If you pull out the failed I/O module, do not insert it again.
- When you replace the I/O module, do not insert an I/O module that is not assured as normal.

If you do not observe these precautions, the field side may be adversely affected if the inserted module is faulty.

SEE ALSO For more information about the procedures for replacing ProSafe-RS devices, refer to:

I1.2, “Maintenance for ProSafe-RS equipment” on page I1-9

H. Monitoring the SCS status

You can monitor the SCS status from the following windows:

- The SCS Status Overview window can be used to view the status of SCSs that are registered in the RS project.
- The State Management window can be used to check the detailed status of the specified SCS.
- The IOM Report can be used to check the detailed status of I/O modules.
- The Diagnostic Information window can be used to check the diagnostic information messages that are generated in SCS.

TIP

- In this manual, the safety control unit and the safety node unit are called as CPU node and FIO node, respectively.
- In this document, I/O shutoff switches and DO shutoff switches of the universal type I/O module and are referred to as an output shutoff switch.

H1. SCS status display

The status of SCS is displayed in the following windows:

- SCS Status Overview window
- SCS State Management window

This section describes how to display and operate these windows.

H1.1 SCS status overview

The SCS Status Overview window displays a list of SCSs assigned to the given RS project. In addition to the current operating conditions of SCSs, it also displays if there is any diagnostic information messages from any of the SCS diagnostic functions; it is easy to know which SCS has errors.

How to display the SCS Status Overview window

The SCS Status Overview window can be launched using the following two methods:

- From the Launcher menu of SCS Manager
- From the [Start] menu of Windows

From the Launcher Menu of SCS Manager

1. Select [Maintenance] from the [Tools] menu of SCS Manager.
   The Maintenance Launcher menu appears.
2. Select [SCS Status Overview] from the Maintenance Launcher menu.
3. Enter your password.
   Password entry is not required when the Access Control and Operation History Management Package is used.

   The SCS Status Overview window is displayed.

From the Start menu of windows

1. Start SCS Status Overview.
2. Enter your password.
   When Windows authentication mode is set, enter a password. When the Access Control and Operation History Management Package is applied, enter the name and password of the engineer.

   The SCS Status Overview window is displayed.

SCS Status Overview window structure

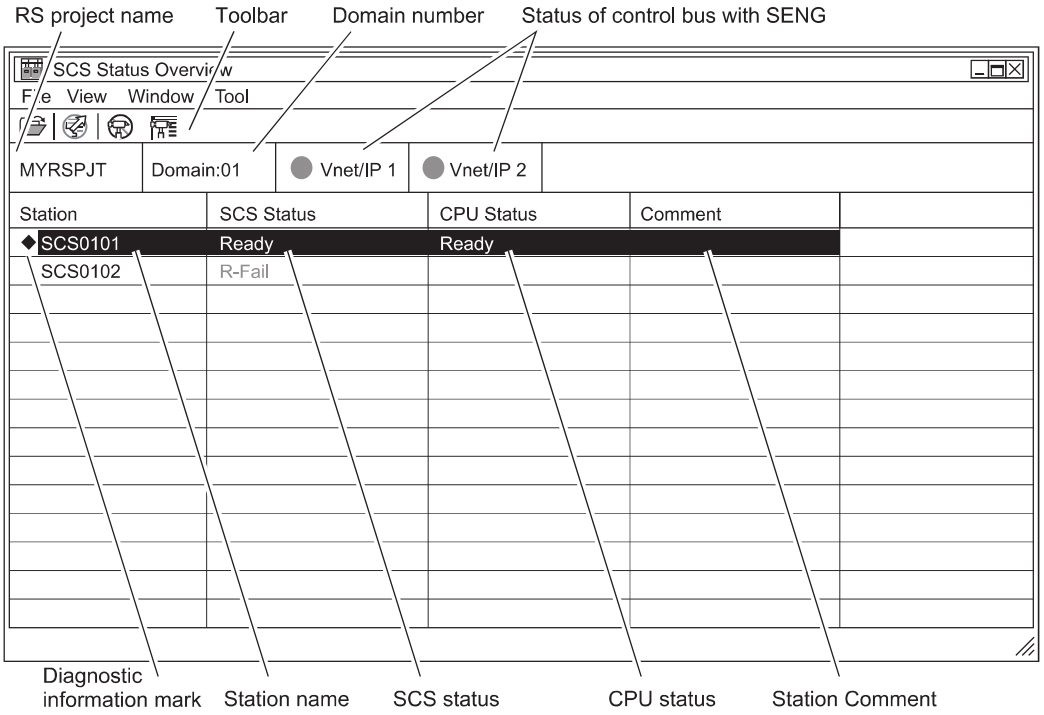

Figure H1.1-1 SCS Status Overview window structure

The components of the window are explained as follows.

Toolbar

The following buttons are provided on the toolbar.

Table H1.1-1 Toolbar buttons

Button	Name	Description
	Open	Call up Project Selection dialog box.
	Diagnostic Information	Call up Diagnostic Information window.
 (*1)	Time Setup	Call up Adjust Time dialog box.
	Setup Tool	Call up Setup Tool.

*1: Not available when using SCS Simulator.

Call up Project Selection dialog box

Click this button to open the Project Selection dialog box, where you can switch between RS projects.

Call up Diagnostic Information window

Click this button to open the Diagnostic Information window related to the SCS selected in the SCS Status Overview window. The Diagnostic Information window allows you to perform confirmation, deletion, printing and saving to file operations on the diagnostic information managed by SCS.

Call up Adjust Time dialog box

The Adjust Time dialog box allows you to set the system date and time. In the case of a CENTUM integration structure, the system time on the CENTUM side is also changed.

But in the following cases, the system time cannot be changed:

- When an SNTP server is connected on the Vnet/IP network and the system time is synchronized with the standard time, the system time cannot be changed from the SENG.
- When a V net router style below S3 is used, the system time of the Vnet/IP network cannot be changed from the SENG in the V net domain.

SEE ALSO For more information about time setting, refer to:

I3., “Setting system time” on page I3-1

Call up Setup Tool

Setup Tool allows you to customize the operating environment of SCS Maintenance Support Tool.

SEE ALSO For more information about setup tool, refer to:

A6.3, “Customization of the SCS Maintenance Support Tool window” in ProSafe-RS User’s Guide (IM 32P01B10-01EN)

System status list view

This view shows a list of operation information of SCSs (whole status and CPU status) in a RS project. The operating status of the control bus connected from the SENG is displayed in the upper part of the list view.

Diagnostic information marks are displayed to the left of SCS names for which diagnostic information messages have been generated. If any of the diagnostic information messages is not acknowledged, the diagnostic information marks flash.

If you double-click a line of an SCS in the Station name column, the SCS State Management window for the corresponding SCS opens.

Table H1.1-2 Items displayed in System status list view

Item	Description
RS Project name	RS project name
Domain number	Domain number to which the local SENG belongs
V net or Vnet/IP status	Status of the control bus to which the local SENG is connected
Diagnostic information mark	Presence of diagnostic information messages and their acknowledgement status
Station name	Station name of an SCS
SCS status	Status of an SCS
CPU status	Status of the SCS’ CPU
Station comment	SCS station comments

Control bus status

Indicates the name and status of the control bus on which the SENG is connected.

Table H1.1-3 Display of V net or Vnet/IP status

Status	Display	Display color
Normal	●	Green
Error	×	Red

Diagnostic information mark

These are used to indicate whether there are any diagnostic information messages, and their acknowledgement status.

Table H1.1-4 Display of diagnostic information marks

Status	Display	Display color
Indicates that the diagnostic information messages exist. Flashes if unacknowledged messages exist.	◆	Red
Indicates that all messages are acknowledged and errors exist in nodes or input/output modules.	◇	Red
Indicates that all messages are acknowledged and deleted, and no error exists in nodes or input/output modules.	(No display)	

SCS status

Indicates the status of entire SCS.

Table H1.1-5 Display of SCS status

Status	Display	Display color
Normal	Ready	
Copying	Copy	Blue
Communication Error	Communication Error (*1)	Red
SCS Simulator is running	Test	

*1: "Communication Error" is displayed when SCS stops. It indicates that the connection for communication is not established.

CPU status

Indicates status of SCS CPU.

Table H1.1-6 Display of CPU status

Status	Display	Display color
Normal. CPUs on both sides are normal in the case of duplex configuration.	Ready	
Abnormal. CPUs on both sides are abnormal in the case of duplex configuration.	Fail	Red
CPU on the right side is abnormal in the case of duplex configuration	R-Fail	Red
CPU on the left side is abnormal in the case of duplex configuration	L-Fail	Red

H1.2 SCS State Management window

The SCS State Management window displays detailed information about the operating status of CPU modules and input/output modules for a single SCS. If there is an error, the erroneous area is shown using a different color. It also displays whether or not there are any messages that have not been acknowledged.

The SCS State Management window allows you to perform the following operations:

- IOM Download operation, Output Enable Operation and Start Output Module operation
- Display of detailed information of each input/output module

How to display the SCS State Management window

The SCS State Management window can be launched using the following two methods:

- From the Launcher menu of SCS Manager
- From the SCS Status Overview window

From the Launcher menu of SCS Manager

1. From the menu bar of SCS Manager, select [Tools] > [Maintenance].
   The Maintenance Launcher menu appears.
2. Select [SCS State Management] from the Maintenance Launcher menu.
3. Enter your password.
   Password entry is not required when the Access Control and Operation History Management Package is used.

   The SCS State Management Window is displayed.

SEE ALSO For more information about security-related operations of the SCS Maintenance Support Tool, refer to:

B5., “Security of SCS Maintenance Support tool” in ProSafe-RS User’s Guide (IM 32P01B10-01EN)

From the SCS Status Overview window

Double-click the station name of an SCS in the SCS Status Overview window. The SCS State Management window for that SCS appears.

SCS State Management window structure

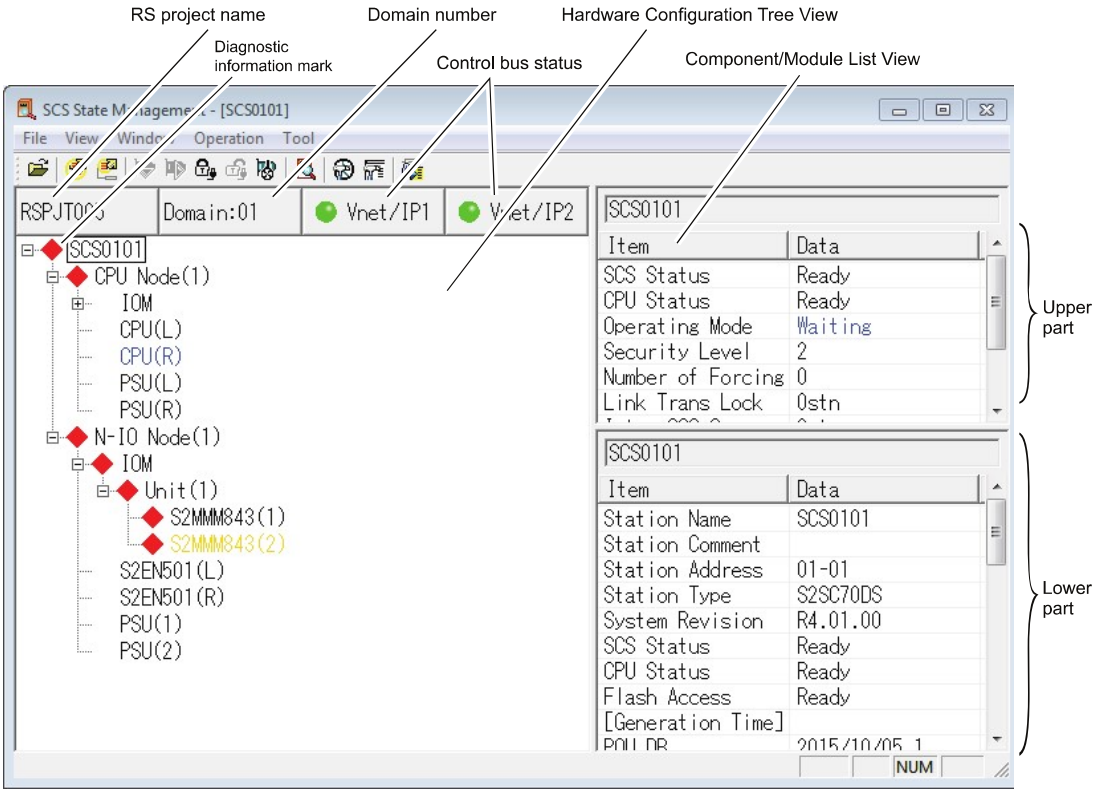

Figure H1.2-1 SCS State Management window structure

TIP

- For SCS that supports SIL 3, SEC402, SEC401, SNT401, SNT501, SNT411, SNT511, and SNT10D are not displayed.
- For SCS that supports SIL 2, L1EC402, L1EC401, L1NT401, L1NT501, L1NT411, L1NT511, and L1NT10D are not displayed.

The components in the window are explained as follows.

Toolbar

The following buttons are provided on the toolbar.

Table H1.2-1 Toolbar buttons

Button	Name	Description
	Open	Call up Project Selection dialog box.
	Diagnostic Information	Call up Diagnostic Information window.
	Common Diagnostic Information	Call up Diagnostic Information window (common).
 (*1)	IOM Load	Call up IOM Download tool
 (*1)	Start output module	Output Module Start

Continues on the next page

Table H1.2-1 Toolbar buttons (Table continued)

Button	Name	Description
 (*1)	Disable Maintenance port	Call up the NIU maintenance port setting tool. To disable the port.
 (*1)	Enable Maintenance port	Call up the NIU maintenance port setting tool. To enable the port.
	I/O Channel Status	Call up I/O Channel Status dialog box.
 (*1)	System Report	Call up System Report dialog box.
 (*1)	Time Setup	Call up Adjust Time dialog box.
	Setup Tool	Call up Setup Tool.
	SCS Status Overview	Call up SCS Status Overview window.

*1: Not available when using SCS Simulator.

Call up Project Selection dialog box

Click this button to open the Project Selection dialog box, where you can switch between RS projects.

Call up Diagnostic Information window

Click the following buttons to open the Diagnostic Information window. The icon on the button changes if there are diagnostic information messages.

- [Diagnostic Information] Button
  This button calls up all diagnostic information messages from the hierarchy tree selected in Hardware Configuration Tree View, to be displayed in the Diagnostic Information window. For example, if you click this button when selecting a node, all diagnostic information messages common to this node and those for all input/output modules for the node and nodes below it are displayed together.
- [Common Diagnostic Information] Button
  This button calls up only diagnostic information messages for the tree selected in Hardware Configuration Tree View to be displayed. For example, if you click this button when selecting a node, only diagnostic information messages common to this node will be displayed in the Diagnostic Information window.

  The [Common Diagnostic Information] button can be used when a station or a node is selected on Hardware Configuration Tree View.

The Diagnostic Information window allows you to perform acknowledgement, deletion, printing and saving to file operations on diagnostic information managed by the SCS.

SEE ALSO For more information about Diagnostic information window, refer to:

H5.2, “Diagnostic Information window” on page H5-3

Call up IOM Download tool

The IOM Download tool is used to recover when input/output modules are replaced or input/output modules fail.

If the user does not have the authority to write, the [IOM Load] button is grayed out and disabled.

SEE ALSO For more information about IOM download tool, refer to:

I4.6, “IOM Download tool” on page I4-80

Output module start

If an error serious enough to activate the Output Shutoff switch occurs, there is a case where the output module stops its output and waits for the Output Module Start depending on an error cause. Perform the Start Output Module operation to start the output modules whose output is stopped. Note that even if you restart the output module, the output of all channels of the output module remain disabled. In order to output the result of application logic from the output module on the control side, perform the Output Enable Operation as well.

If the user does not have the authority to write, the [Start output module] button is grayed out and disabled.

SEE ALSO For more information about starting output module and the Output enable operation, refer to:

C8., “Output enable operation” on page C8-1

Call up I/O Channel Status dialog box

The I/O Channel Status dialog box displays the statuses of the channels of all input/output modules of the SCS in list format. This dialog box also allows you to enable the output of channels whose output are disabled (Output Enable Operation).

SEE ALSO For more information about Output enable operation, refer to:

C8., “Output enable operation” on page C8-1

For more information about I/O channel status, refer to:

H4., “Displaying I/O channel status” on page H4-1

Call up NIU maintenance port setting tool

The NIU maintenance port setting tool is called to enable or disable the NIU maintenance port. It can be called after selecting the following components in Hardware Configuration Tree View. You can also called it from menu bar.

Table H1.2-2 Setting method to enable or disable the NIU maintenance port

Objective	How to start the tool
Disable the maintenance port of all the nodes of each station collectively.	Select the station from Hardware Configuration Tree View, and then select [Operation] > [Disable Maintenance port]. Or, click the [Disable Maintenance port] button on the tool bar.
Disable the maintenance ports on a per node basis	Select the N-IO node from Hardware Configuration Tree View, and then select [Operation] > [Disable Maintenance port]. Or, click the [Disable Maintenance port] button on the tool bar.
Enable the maintenance ports on a per node basis	Select the N-IO node from Hardware Configuration Tree View, and then select [Operation] > [Enable Maintenance port]. Or, click the [Enable Maintenance port] button on the tool bar.

Call up System Report dialog box

The SCS Report dialog box displays the status of the displayed SCS as character strings. IOM Report dialog box also displays the status of the displayed input/output modules. This function allows printing reports and save them in files in text format.

SEE ALSO For more information about system reports, refer to:

H2., “System reports” on page H2-1

Call up Adjust Time dialog box

Click this button to open the Adjust Time dialog box.

SEE ALSO For more information about time setting, refer to:

I3., “Setting system time” on page I3-1

Call up Setup Tool

Setup Tool allows you to customize the operating environment of SCS Maintenance Support Tool.

SEE ALSO For more information about setup tool, refer to:

A6.3, “Customization of the SCS Maintenance Support Tool window” in ProSafe-RS User’s Guide (IM 32P01B10-01EN)

Call up SCS Status Overview window

Click this button to return to the SCS Status Overview window.

Hardware Configuration tree view

This view displays the hardware configuration of a single SCS in tree format. The upper part of the tree view shows the status of the control buses connected to the SCS.

The CPU node displays the CPU module, power supply module and I/O module. The I/O module of the CPU node also includes the N-ESB bus coupler module. The FIO node displays the power supply module and the I/O module. The N-IO node displays the power supply module, I/O module and N-ESB bus module. If there is any diagnostic information message for any hardware components displayed in tree format, a diagnostic information mark is displayed at the left of each component. Since diagnostic information marks are displayed on the alarm layer, if an error is detected in an I/O module, a diagnostic information mark will also appear in the I/O node and SCS of the upper components. In this way, the user can simply display the upper components to check whether any lower diagnostic information messages exist in the alarm layer. If an error is detected in the upper component, the lower components show the status that is obtained before the error has occurred in the upper component.

In the case of dual redundant input/output modules, diagnostic information messages for both sides are displayed regardless of which input/output module you select.

If there are any diagnostic information messages that have not been acknowledged, the diagnostic information mark flashes.

Double-click the name of component or input/output module to display detailed information of the selected item in Component/Module List View.

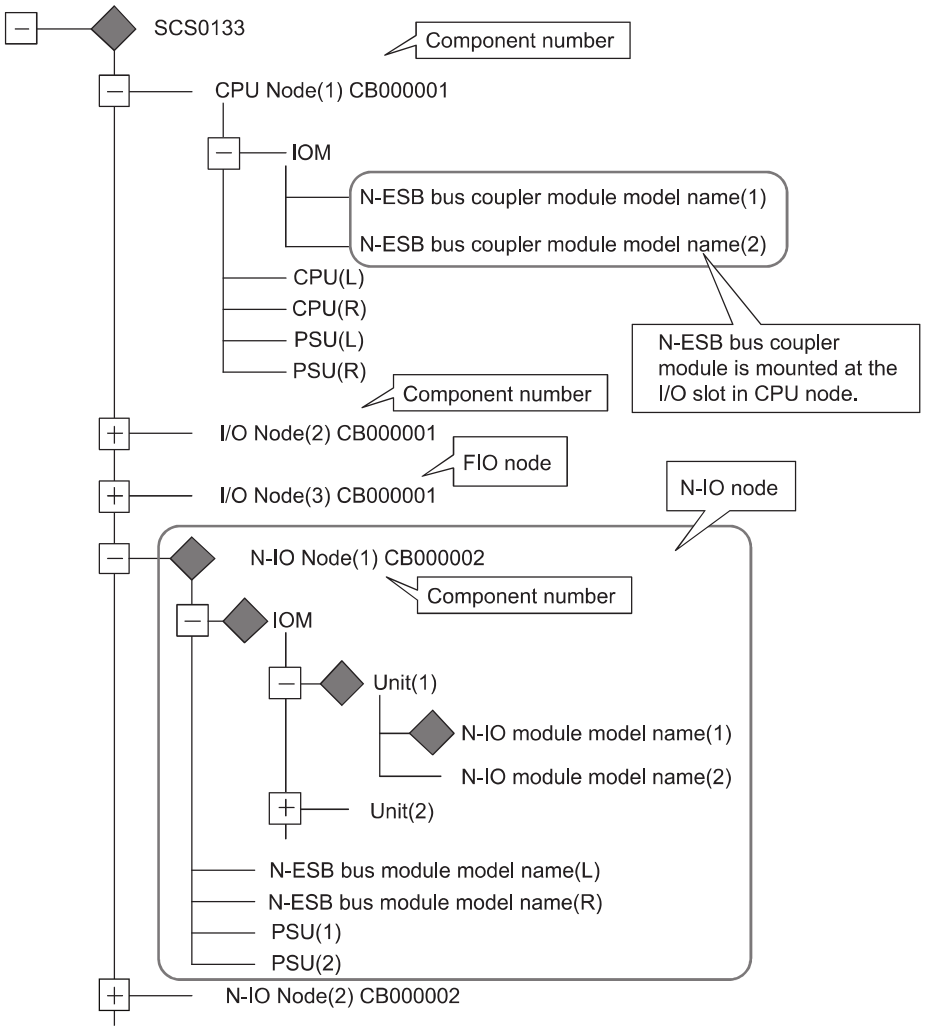

Figure H1.2-2 Hardware Configuration tree view

Table H1.2-3 Items displayed in Hardware Component tree view

Display items	Description
RS Project name	RS project name
Domain number	Domain number to which the SCS belongs
V net or Vnet/IP Status	Status of the control bus to which the SCS is connected
Diagnostic information mark	Presence of diagnostic information messages and their acknowledgement status
Component name or module name	Node or I/O module names (*1)

*1: If ALR111M is set when the I/O module is defined, ALR111 is displayed in the SCS State Management window. Similarly ALR121 is displayed for ALR121M and ALE111 is displayed for ALE111M.

Control bus status

It displays the status of the control bus where the SCS is connected. The following table shows the relationship between the status, display, and display colors of the control bus.

Table H1.2-4 Display of V net or Vnet/IP status

Status	Display	Display color
Normal	●	Green
Error	×	Red

Diagnostic information mark

The relationship between the status, display, and the display colors of the diagnostic information mark is shown in the following table.

Table H1.2-5 Display of Diagnostic information mark

Status	Display	Display color
Indicates that diagnostic information messages exist. Flashes if unacknowledged messages exist.	◆	Red
Indicates that all messages are acknowledged and errors exist in nodes or input/output modules.	◇	Red
Indicates that all messages are acknowledged and deleted, and no error exists in nodes or input/output modules.	(No display)	

Component name or module name

The relationship between component name or module name and the display colors is shown in the following table.

Table H1.2-6 Display of component name or module name status

Status	Display color	Remark
Normal		When using SCS Simulator, the components and modules are displayed as Normal even though they are not physically installed.
Error	Red	
Standby	Yellow	
Hardware ready	Blue	This status indicates that an APC is being executed in the case of CPU module, and information is being copied from the control side to the standby side.
Copying	Blue	This status indicates that information is being copied from the control side to the standby side in the case of SCS.
Waiting for startup	Blue	In the case of output module, this status indicates that the output module is waiting for startup.

Component names or module names are displayed with one of the following characters attached to the right of the name.

Table H1.2-7 Characters attached to the component name and module name

Component name, module name.	Displayed characters	Attached character
CPU node	CPU Node	Node number (1)
FIO node	I/O Node	Node number (2) to (14)
N-IO node	N-IO Node	Node number (1) to (32)
Component Number		Set component number
CPU module	CPU	(L) or (R) for the CPU node. Automatically attached after the redundancy is determined from the SCS station model.
Power supply module	PSU	(L) or (R) for the CPU node and FIO nodes (1) or (2) for N-IO nodes
Unit	Unit	Unit number (1) to (6) for N-IO nodes

Continues on the next page

Table H1.2-7 Characters attached to the component name and module name (Table continued)

Component name, module name.	Displayed characters	Attached character
Input/output module		For the CPU node and FIO nodes, the module model and slot number (1) to (8) are attached under IOM. For N-IO nodes, the module model and (1) to (2) are attached under Unit.
ESB bus module		For the CPU node and FIO nodes, the module model and control bus number (1) or (2) are attached.
N-ESB bus coupler module		For the CPU node, the module model and control bus number (1) or (2) are attached.
N-ESB bus module		For N-IO nodes, the module model and (L) or (R) are attached.

Upper part of Component/Module list view

The following items are always displayed in the upper part of the list view.

- SCS Status
- CPU Status
- Operating mode
- SCS security level
- Number of variables locked by the forcing function
- Number of stations locked in the SCS Link Transmission
- Subsystem Communication Data Locking/Unlocking
- Number of locked stations in the inter-SCS safety communication
- Number of safety subsystem communication I/O locks (only for S2SC70)
- Status of the NIU maintenance port (only for S2SCS70)

Lower part of Component/Module list view

The lower part of the list view displays detailed information about the operating status of the component or module selected by double-clicking in Hardware Configuration Tree View.

Content enclosed in [ ] indicates an index.

The display for each item varies depending on the component or input/output module selected in Hardware Configuration Tree View.

Lower part of list view when a station is selected

The following table shows the contents that are displayed in the lower part of the list view when a station is selected.

Table H1.2-8 Status display (When a station is selected)

Item	Description
Station name	Station name of the SCS
Station comment	Station comments for the SCS
Station Address	Shown in the form of "Domain number-Station number".
Station Type	SCS station type
System Revision	Release number of the system program loaded on the SCS

Continues on the next page

Table H1.2-8 Status display (When a station is selected) (Table continued)

Item	Description
SCS Status	Status of SCS
CPU Status	Status of CPU of the SCS
Flash Access	[Ready] is displayed while in the normal state, and [Writing] (blue) is displayed if the flash memory is being written.
Generation Date/Time	Date and Time when the POU DB, Variable DB, System DB and Integration DB were created.
Application time (*1) (*2)	Actual scan period (msec), set scan period (msec), and program execution time (%)
CPU Idle Time (*1)	Idle time (sec)
Communication Load (*1)	Average value (%) and current value (%)
Control Status	Displayed as [Run] when running and as [Stop] (red) when stopped.
Operating Mode	The operating mode of SCS is displayed in the corresponding color.
Security Level	Displays the security level of SCS. The security level is displayed in blue for Levels 1 and 0.
Number of Forcing	Displays the number of variables that have been locked using the forcing function. The number is displayed in blue if one or more locked variables exists.
Number of stations locked in the SCS Link Transmission	Displays the number of stations being locked in the SCS Link Transmission. The number and [Stn] are displayed in blue if there is one or more locked stations.
Number of locked stations in the inter-SCS safety communication	Displays the number of stations that are locked in the inter-SCS safety communication. The number and "Stn" are displayed in blue if locked stations exist.
Lock of subsystem communication data	[YES](blue) is displayed if the subsystem communication data are locked and [No] is displayed if the subsystem communication data are not locked. If the SCS does not have any communication module, [No] is displayed.
Number of safety subsystem communication I/O locks (*3)	Displays the number of communication definitions locked with safety subsystem communication. The number is displayed in blue if one or more locked communication definitions exist.
Status of the NIU maintenance port (*3)	When NIU maintenance port is enabled, "Enable" is displayed in red; when it is disabled, "Disable" is displayed.

*1: When SCS Simulator is running, the program execution time is displayed as 100, and CPU idle time and communication load are displayed as 0.
*2: In the case of SCS with R2.02 or earlier system program, actual scan period is not displayed. The set scan period is displayed in the position of actual scan period.
*3: Displayed only for S2SCS70.

- SCS Status

Table H1.2-9 Display of station status

Status	Display	Display color
Normal	Ready	
Copying	Copy	Blue
Communication Error (*1)	Communication Error	Red
SCS Simulator is running	Test	

*1: "Communication error" is also displayed when SCS is stopped.

- CPU Status

Table H1.2-10 Display of CPU status

Status	Display	Display color
Normal. CPUs on both sides are normal in the case of duplex configuration.	Ready	
Abnormal. CPUs on both sides are abnormal in the case of duplex configuration.	Fail	Red
CPU on the right side is abnormal in the case of duplex configuration	R-Fail	Red
CPU on the left side is abnormal in the case of duplex configuration	L-Fail	Red

- Operating Mode

Table H1.2-11 Display of Operating mode

Status	Display	Display color
Stop status (*1)	Stop	Red
Offline Downloading (*1)	Loading	Red
Initialized status	Initial	Red
Waiting for output enable request	Waiting	Blue
Operating	Running	

*1: Normally, these states are not displayed.

Lower part of list view when a CPU node is selected

The following table describes the contents that are displayed in the lower part of the list view when the CPU node is selected.

Table H1.2-12 Status display (when a CPU node is selected)

Item	Description
Node Number	Displays the node number 1.
Component Number (*1)	Displays the component number.
Node Comment	Displays comments for the node.
Node Status	[Ready] is displayed when the status is normal, [Fail] (red) is displayed if the status is abnormal, and [Communication Error] (red) is displayed if the communication status is abnormal.
IRIG-B Status	Displayed only when IRIG-B time synchronization is applied. [Ready] is displayed when the status is normal and [Fail] (red) is displayed if the status is abnormal.
Time Sync	Indicates the time synchronization status. [Vnet/IP] is shown if not synchronized with the time on the SNTP server; [SNTP] is shown if synchronized.
Intake Air Temperature	[Ready] is displayed when the status is normal and [Fail] (red) is displayed if the status is abnormal.
Exhaust Air Temperature	
Battery Temperature	
SCU Fan (*2)	
Battery Status	
Operation data reset switch(*3) (*4)	Displays the status of operation data reset switch. [Hold] is displayed when it is set to maintain NVARM at power recovery and [Reset] (red) is displayed when it is set to clear it.
ESB Bus Status (*5)	[Ready] is displayed when the status is normal and [Fail] (red) is displayed if the status is abnormal.

*1: Displayed for S2SC70 or L1SC70.
*2: Not available if the model of SCS does not have a fan.
*3: Operation data reset switch item is displayed for SSC60 or S2SC70. If S2CP471 is installed in SSC60 or S2SC70, setting status of Operation data reset switch appears. If other than S2CP471 is installed, "Hold" is always displayed.
*4: Displayed for L1SC70.
*5: Not displayed for SCS with CPU node only or for S2SC70/L1SC70.

TIP

The status of Operation data reset switch can be checked by SCS State Management Window, LED on the CPU module, SYS_DIAG function block, or the SCS Station Status Display view on the HIS.

Lower part of the list view when the CPU module of the CPU node is selected

The following table shows the contents that are displayed in the lower part of the list view when the CPU module of the CPU node is selected.

Table H1.2-13 Status display (When a CPU module is selected)

Item	Status	Display	Display color
CPU Status	Normal	Ready	
	Error	Fail	Red
	Standby	Stand-By	Yellow
	Hardware ready	Hard Ready	Blue
	Communication Error	Communication Error	Red
Bus Status	Normal	Ready	
	Error	Fail	Red

Lower part of list view when a CPU node power supply module is selected

The following table shows the contents that are displayed in the lower part of the list view when the power supply module of the CPU node is selected.

Table H1.2-14 Contents of the status display (when PSU is selected)

Item	Status	Display	Display color
PSU Status	Normal	Ready	
	Error	Fail	Red
	Communication Error	Communication Error	Red
24 V DC Power Supply Status	Normal	Ready	
	Error	Fail	Red

Lower part of the list view when the N-ESB bus coupler module of the CPU node is selected

The following table shows the contents that are displayed in the lower part of the list view when the N-ESB bus coupler module of the CPU node is selected.

Table H1.2-15 Contents of the status display (when the N-ESB bus coupler module of the CPU node is selected)

Item	Status	Display	Display color
I/O module model		Input module model	

Continues on the next page

Table H1.2-15 Contents of the status display (when the N-ESB bus coupler module of the CPU node is selected) (Table continued)

Item	Status	Display	Display color
I/O module status	Normal	Ready	
	Error	Fail	Red
	Transmission error	Communication Error	Red
Bus status	Normal	Ready	
	Error	Fail	Red

Lower part of the list view when the representative I/O module of the CPU node is selected

In the CPU node, the status of the I/O module or N-ESB bus coupler module can be displayed in the representative I/O module. The following table shows the contents that are displayed in the lower part of the list view when the representative I/O module with N-ESB bus coupler module installed is selected in the CPU node.

Table H1.2-16 Contents of the status display (when the representative IOM of the CPU node is selected: N-ESB bus coupler module)

Item	Status	Display	Display color
Representative I/O module status	Normal	Ready	
	Error	I/O Fail	Red
	Transmission error	Communication Error	Red
Representative channel status	Normal	Ready	

Lower part of the list view when an FIO node is selected

The following table shows the contents that are displayed in the lower part of the list view when an FIO node is selected.

Table H1.2-17 Status display (when an I/O node is selected)

Item	Description
Node Number	Displays the node number.
Component Number	Displays the component number. (*1)
Node Comment	Displays comments for the node.
Node Status	Displays either normal or abnormal.

*1: When an FIO node is selected in S2SC70 or when it is L1SC70

- Node status

Table H1.2-18 Display of Node status

Status	Display	Display color
Normal	Ready	
Error	Fail	Red
Communication Error	Communication Error	Red

Lower part of the list view when the ESB bus interface module of an FIO node is selected

The following table shows the contents that are displayed in the lower part of the list view when the ESB bus interface module of an FIO node is selected.

Table H1.2-19 Status display (when an I/O node ESB bus interface module is selected)

Item	Status	Display	Display color
ESB-S Status	Normal	Ready	
	Error	Fail	Red
	Communication Error	Communication Error	Red

Lower part of the list view when the power supply module of an FIO node is selected

The following table shows the contents that are displayed in the lower part of the list view when the power supply module of an FIO node is selected.

Table H1.2-20 Status display (when an I/O node power supply module is selected)

Item	Status	Display	Display color
PSU Status	Normal	Ready	
	Error	Fail	Red
	Communication Error	Communication Error	Red
24 V DC Power Supply Status	Normal	Ready	
	Error	Fail	Red

Lower part of the list view when an N-IO node is selected

The following table shows the contents that are displayed in the lower part of the list view when an N-IO node is selected.

Table H1.2-21 Content of the status display (when an N-IO node is selected)

Item	Status	Display	Display color
Node number		Node number	
Component number		Component number	
Node comment		Node comment	
Node status	Normal	Ready	
	Error	Fail	Red
	During maintenance	Maintenance	Blue
	Transmission error	Communication Error	Red
NIU maintenance port status	Enable	Enable	Red
	Disable	Disable	
External alarm input	Normal	Ready	
	Error	Fail	Red
	Diagnosis by external alarm input is disabled	Blank	
Temperature status	Normal	Ready	
	Error	HI, LO	Red

Lower part of the list view when the N-ESB bus module of an N-IO node is selected

The following table shows the contents that are displayed in the lower part of the list view when the N-ESB bus module of the N-IO node is selected.

Table H1.2-22 Contents of the status display (when the N-ESB bus module of an N-IO node is selected)

Item	Status	Display	Display color
N-ESB-S status	Normal	Ready	
	Error	Fail	Red
	During maintenance	Maintenance	Blue
	Error due to maintenance of one module	Fail (Due to maintenance of one module)	Red
	Transmission error	Communication Error	Red
NIU maintenance port status	Enable	Enable	Red
	Disable	Disable	

Lower part of the list view when the power supply module of an N-IO node is selected

The following table shows the contents that are displayed in the lower part of the list view when the power supply module of an N-IO node is selected.

Table H1.2-23 Contents of the status display (when PSU of an N-IO node is selected)

Item	Status	Display	Display color
PSU status	Normal	Ready	
	Error	Fail	Red
	Transmission error	Communication Error	Red
Detail	Normal (*1)		
	PSU stopped supplying power	Power Off	Red
	PSU output over voltage	Overvoltage	Red

*1: The PSU is normal, or not in the power off or over voltage status.

Lower part of the list view when a unit of an N-IO node is selected

The following table shows the contents that are displayed in the lower part of the list view when a unit of an N-IO node is selected.

Table H1.2-24 Contents of the status display (when a unit of an N-IO node is selected)

Item	Status	Display	Display color
Unit number		Unit number	
Bus status	Normal	Ready	
	Error	Fail	Red
	Communication error	Communication Error	Red

Lower part of list view when the representative Input/Output module is selected

I/O module of each node can be grouped, and the group status can be displayed in the list view as a representative I/O module. Individual I/O modules are displayed under the representative I/O module in tree format.

Table H1.2-25 Contents of the status display (when the representative IOM of a node is selected)

Item	Status	Display	Display color
Representative Input/Output Module Status	Normal	Ready	
	Error	I/O Fail	Red
	Communication Error	Communication Error	Red
Status of Representative Channel	Normal	Ready	
	Error	Channel Fail	Red

Lower part of the list view when an individual I/O module of the CPU node or an FIO node is selected

The following table shows the contents that are displayed in the lower part of the list view when an individual I/O module of the CPU node or an FIO node is selected.

Table H1.2-26 Contents of the status display (when an individual I/O module of the CPU node or an FIO node is selected)

Item	Status	Display	Display color
Input/Output Module Type		I/O module model (*1)	
Input/Output Module Status	Normal	Ready	
	Waiting	Stand-by	Yellow
	Error	Fail	Red
	Waiting for startup	Waiting	Blue
	Communication Error	Communication Error	Red
Bus Status	For each bus, [Ready] is displayed when the status is normal and [Fail] (red) is displayed if the status is abnormal.		
Port status (*2)	Normal	Ready	
	Error (*3)	Error	Red
Channel Status	Normal	Ready	
	IOP+ (*4)	IOP+	Red
	IOP- (*4)	IOP-	Red
	Transmitter failure+ (*5)	TRNS+	Red
	Transmitter failure- (*5)	TRNS-	Red
	Analog input error	OvrRange	Red
	Error	Ch Fail	Red

*1: If ALR111M is set when the I/O module is defined, ALR111 is displayed in the SCS State Management window. Similarly ALR121 is displayed for ALR121M and ALE111 is displayed for ALE111M.
*2: Displayed only when a communication module used for communicating with a subsystem is selected.
*3: With S2LP131, an error is a state where either one or both of a safety subsystem communication path error (SS-SCPATH) and a safety subsystem communication error (SS-SCOM) are occurring.
*4: This is only if an analog input module is used.
*5: Displayed only when an analog input module other than the one for TC/RTD is selected.

Lower part of the list view when an individual I/O module of an N-IO node is selected

The following table shows the contents that are displayed in the lower part of the list view when an individual I/O module of an N-IO node is selected.

Table H1.2-27 Contents of the status display (when an individual I/O module of an N-IO node is selected)

Item	Status	Display	Display color
I/O module model		I/O module model	
I/O module status	Normal	Ready	
	Standby	Standby	Yellow
	Error	Fail	Red
	Transmission error	Communication Error	Red
Bus status	Normal	Ready	
	Error	Fail	Red
Channel status (*1)	Normal	Ready	Red
	IOP+ (*2)	IOP+	Red
	IOP- (*2)	IOP-	Red
	Transmitter failure+ (*2)	TRNS+	Red
	Transmitter failure- (*2)	TRNS-	Red
	Analog input error (*2)	OvrRange	Red
	Barrier missing (*3)	IS Barrier Disconnected	Red
	Barrier connection error (*3)	IS Barrier Configuration Error	Red
	I/O open circuit error (*4)	Open Circuit	Red
	I/O short circuit error (*5)	Short Circuit	Red
	Field failure	Field Side Error	Red
	Error	Ch Fail	Red
Channel signal type	Not used	Blank	
	Current input	(IN) Current	
		(IN) Current - IS (*3)	
	Current input (HART)	(IN) Current - HART	
		(IN) Current - HART - IS (*3)	
	Status input	(IN) Status	
		(IN) Status - IS (*3)	
	Current output	(OUT) Current	
		(OUT) Current - IS (*3)	
	Current output (HART)	(OUT) Current - HART	
		(OUT) Current - HART - IS (*3)	
	Status output	(OUT) Status	
		(OUT) Status - IS (*3)	
	1.3 A status output	(OUT) Status 1.3A*	
		(OUT) Status 1.3A* - IS (*3)	
	2.0 A status output	(OUT) Status 2.0A*	
		(OUT) Status 2.0A* - IS (*3)	

*1: Does not display the status of those channels where an I/O variable are not allocated.
*2: Displayed only if an analog input module is selected.

*3: Displayed only when the intrinsic safety barrier is used.
*4: Displayed only when open circuit detection is set.
*5: Displayed only when "Detect Short Circuit" is set.

H2. System reports

System report includes SCS Report window and IOM Report window in the SCS State Management Window. The above two windows can be used for displaying SCS status and input/output module status respectively. When abnormality occurs, the details displayed on these windows can help analyzing the causes of problems. The reports can be printed out or saved into text files.

SCS Report

SCS Report displays the SCS status.
Select a device item other than the input/output modules in Hardware Configuration Tree View of the SCS State Management window, and then click [System Report] button on the toolbar. The SCS Report dialog box will be displayed.

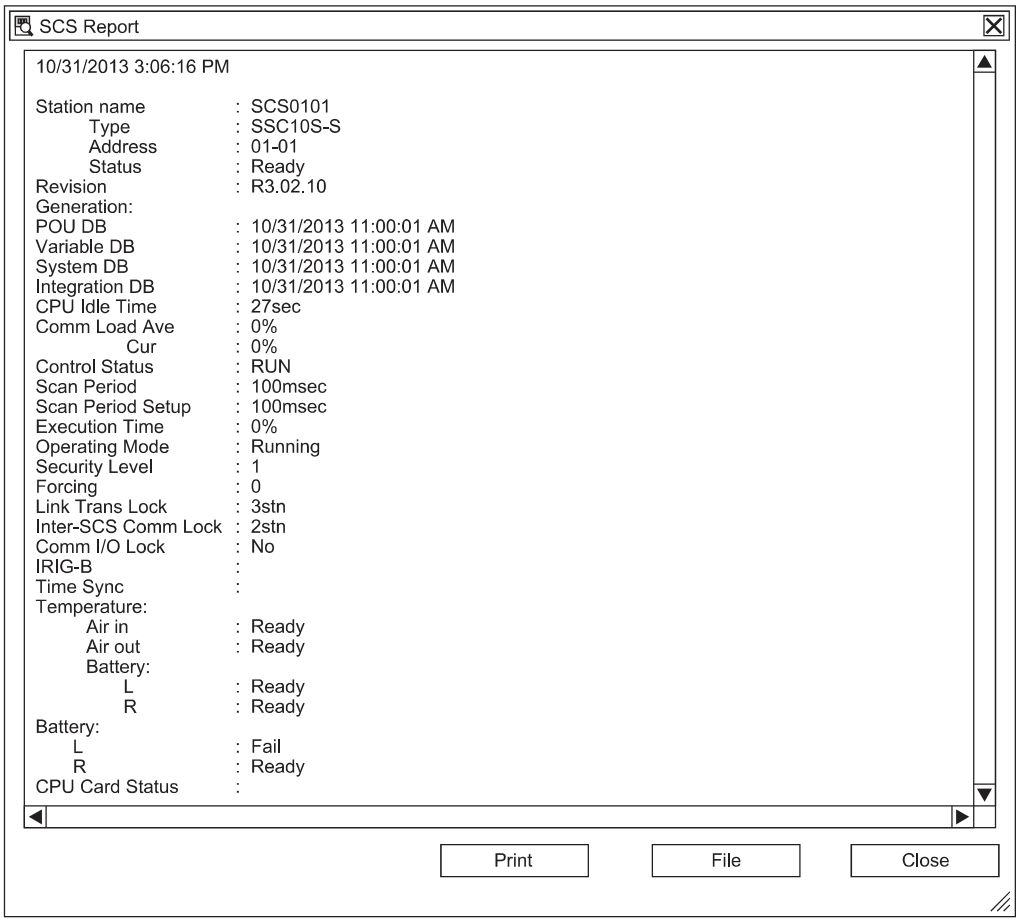

Figure H2-1 SCS Report dialog box

Display example of the SCS report of the system that has a combination of FIO and N-IO

In the SCS report of the system that has a combination of FIO and N-IO, the node status is displayed in the following order: CPU node, FIO node, and N-IO node.

```
**********
FIO Node Status:                          * Discrimination from N-IO node
  Line No.          :
  Node No.          :
  Comment           :
  Component No. :0001                     * Component number
  Com Status (L)  :Ready / Fail
               (R)  :Ready / Fail
  PSU Status (L)  :Ready / Fail
               (R)  :Ready / Fail
  I/O Unit          :Ready / Fail
  Slot No. Type    Status Bus1 Bus2 Port1 Port2 Port3 Port4 Channel
   1      XXXXXX Ready / Fail                          ("XXXXXX" is an IOM model name.)
   2      XXXXXX Ready / Fail
**********

**********
N-IO Node Status:                                      * Discrimination from the existing FIO node
  Node No.          :
  Comment           :
  Component No. :0001                   * Component number
  NIU Status (L)   :Ready / Fail / Fail (Only one module is under maintenance) / Maintenance
               (R)  :Ready / Fail / Fail (Only one module is under maintenance) / Maintenance
  Maintenance Port (L)  :Enabled / Disabled              * NIU maintenance port L/R enable/disable
                       (R)  :Enabled / Disabled
  PSU Status 1    :Ready / Fail         * PSU Status 1/2
               2    :Ready / Fail
  I/O Unit          :Ready / Fail
  Diagnosis         :       * The detected error information is separated with comma for each error and displayed.
  Unit No:    1                         * Unit No: 1 - 6
  BUS Status 1    :Ready                * F-SB bus between NIU and IOM Unit
               2    :Ready
      Slot No. Type     Status In-Bus1 In-Bus2 Channel  * In-Bus1/2
      1       XXXXXX Ready / Fail                      ("XXXXXX" is an IOM model name. )
      2       XXXXXX Ready / Fail
  Unit No:    2
      :
   omitted
      :
**********
```

● Operations in the SCS Report dialog box

Use the following buttons to perform operations.

Table H2-1 Explanation of button names and operations

Button	Description
Print	Print the display of the SCS Report dialog box.
File	Save the display of the SCS Report dialog box (text format).
Close	Close the SCS Report dialog box.

■ IOM Report

The input/output module status or the communication module status detected by the SCS CPU module is displayed in the IOM Report window.
Select the input/output module or the communication module in Hardware Configuration Tree View of the SCS State Management window, and then click [System Report] button on the toolbar. The IOM Report dialog box will be displayed.

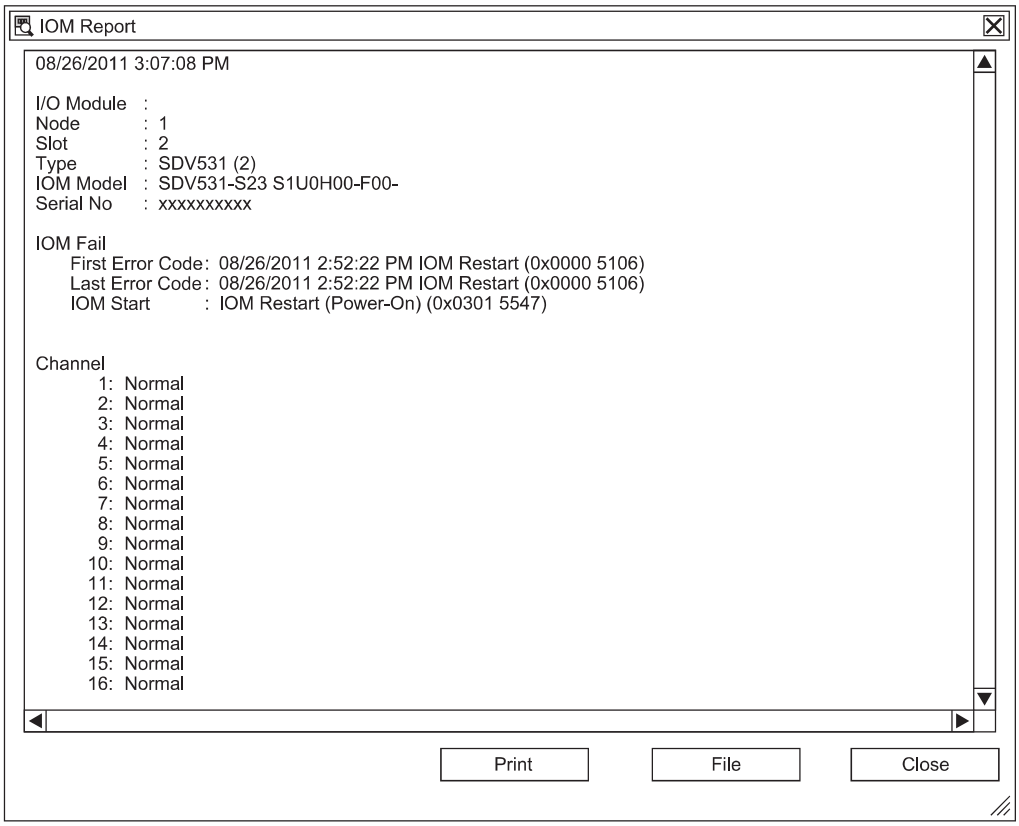

Figure H2-2 IOM Report dialog box

Operations in the IOM Report dialog box

Use the following buttons to perform operations.

Table H2-2 Explanation of button names and operations

Button	Description
Print	Print the display of the IOM Report dialog box.
File	Save the display of the IOM Report dialog box (text format).
Close	Close the IOM Report dialog box.

H3. Checking diagnostic information by using IOM Report

This chapter explains the following items regarding the diagnostic information relating to AIO/DIO modules and communication modules that are displayed in the IOM Report dialog box called from the SCS Maintenance Support Tool.

- Format of diagnostic information displayed in the IOM Report dialog box
- Details of diagnostic information displayed in the IOM Report dialog box

SEE ALSO For more information about IOM Report for the serial communication module, refer to:

H3.2, “IOM Report of communication modules” on page H3-19

Calling the IOM Report

In the Hardware configuration tree view within the SCS State management window of the SCS Maintenance support tool, select an input/output module and click the "System report" button on the tool bar; the IOM Report dialog box appears.

SEE ALSO For more information about the structure and operations of the IOM Report dialog box, refer to:

H2., “System reports” on page H2-1

H3.1 IOM Report of AIO/DIO modules

This section describes the IOM Report for the analog input/output modules (AIO modules) and the digital input/output modules (DIO modules). In the description of these items, AIO/DIO modules are referred to as input/output modules.

Display content in the IOM Report

The IOM Report displays the diagnostic information regarding input/output module errors. The input/output module errors are categorized and displayed as follows:

- Cause of the input/output module error (CPU detection)
  This is a display of the input/output module error status detected by the CPU module of the SCS. The input/output module status as viewed from the CPU (such as No response and HRDY OFF) and other information are displayed. The detailed cause of the input/output module failure is displayed under "Error information inside the input/output module."
- Error information inside the input/output module
  Causes of an error and a recovery are collected from the input/output module, and then displayed.
- Cause of the channel error
  Channel error status is displayed. IOP errors detected by the CPU module and channel errors detected by the input/output module are displayed. If an IOM module becomes error due to an error in an I/O channel, multiple error messages regarding the channel of the I/O module maybe displayed.

TIP

If a bus error occurs between an input/output module and a CPU module, the following codes indicating the source of the error are reported in the IOM Report generated after operations are restored.

- Cause of the input/output module error (CPU Detection)
  No response from the input/output module. CPU is unable to retrieve error information from the input/output module.
- Error information inside the input/output module
  Communication cannot be established with the host CPU or bus for the input/output module, resulting in a host failure error and a fallback operation.

Note also that if there is an input/output module hardware failure, HRDY OFF is displayed in Cause of the input/output module error (CPU Detection) and you can identify the cause of the failure from the error information in the input/output module.

H3.1.1 Display format for the IOM Report of FIO

If the I/O module of FIO is used, the IOM report is displayed in the following format.

```
I/O Module:
Node            : 2
Slot            : 1
Type            : SAI143S
IOM Model       : SAI143-S03 S1U0H00- F00-
Serial No       : XXXXXXXX

(Current status)          : (Current error information (CPU detection))
        First Error Code  : (Information for first error)
        Last Error Code   : (Information at recovery)
         (Error information inside the input/output module)

Channel
1:          (Channel status) (The latest channel error)
              (Cause of the channel error detected by the input/output module)
2:          (Channel status) (The latest channel error)
              (Cause of the channel error detected by the input/output module)
              .
              .

16:         (Channel status) (The latest channel error)
              (Cause of the channel error detected by the input/output module)

(4 kbyte dump display)
```

An example of I/O module error

This is the explanation of the example of the IOM Report that appears when you select a module and call it under the following circumstance.

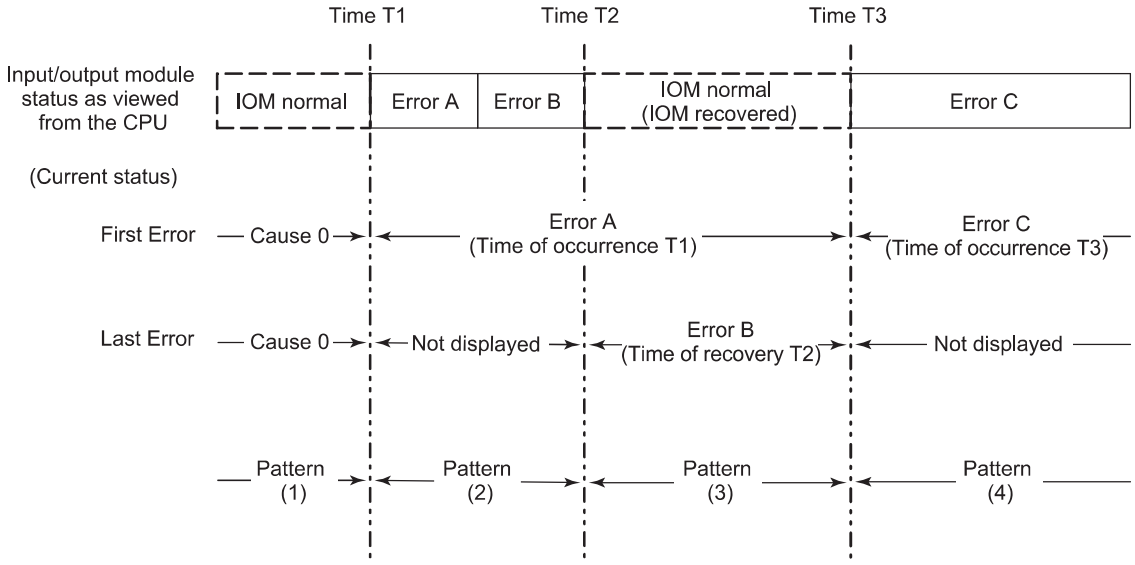

Figure H3.1.1-1 Input/Output module error

The following information will be displayed in each of the situations shown in the figure.

- Pattern (1)

This is a state where there is no input/output module error after the initial cold start of the CPU. In this case, the current status (normal) will be displayed. The first and last error code lines will display the time when the input/output module was started and the cause (Cause 0), respectively.

- Pattern (2)
  This is a state where there is an input/output module error. The current status and the current error content, as well as the time of the first error occurrence (T1) and the first error (Error A), will be displayed. The last error will not be displayed. (The last error code line will not be displayed.)
- Pattern (3)
  This is a state where the input/output module has recovered from the error. The current status (normal), the time of the first error occurrence (T1), the first error (Error A), the time of recovery (T2), and the last error (Error B) will be displayed.
- Pattern (4)
  This is a state where there is an input/output module error. The time of the first error occurrence (T3) and the first error (Error C) will be displayed.

Display format details (I/O module details)

Cause of the input/output module error and error information inside the input/output module are displayed in the following format.

Table H3.1.1-1 Cause of the Input/Output module error and error information inside the Input/Output module

Display item	Description
Current status	The current IOM status will be displayed in the following format. IOM Normal/IOM Fail/IOM Fail (Output Shutoff)
Current error information (CPU detection)	The cause of the current input/output module error detected by the CPU will be displayed with error code. Example: No response (0x0000 5101) Display condition: The information is displayed when there is an input/output module error.
Information for first error	The time of the first error occurrence detected by the CPU (when the input/output module status changed from normal to error) and the error information will be displayed with error code. Example: 20/4/2005 12:34:56 IOM Fail (HRDY OFF) (0x0000 5105) Display condition: The information is displayed when an error occurs with the input/output module even once.
Error information at recovery	The recovery time of the I/O module and the latest error information will be displayed with error code. Example: 20/4/2005 12:50:56 IOM Restart (0x0000 5106) Display condition: The I/O module is currently normal and the displayed information is the latest error in the past.
Information of errors within the I/O module (*1)(*2)	How the input/output module was started and the error code inside the input/output module will be displayed. Example 1: When the input/output module is normal IOM Start: IOM Restart (Power On) (0x0301 5547) Example 2: When there is an input/output module error IOM Fail: IOM Readback Error (0x0101 5502) Display condition: The information is displayed when the cause of the error is stored inside the input/output module, and the input/output module information can be obtained.

*1: The "Information of errors within the I/O module" lists the details of factors of the "Current status" that are due to the I/O module. The status information for individual channels is not included here.
*2: The "starting factors" displayed in the "Information of errors within the I/O module" are detailed factors upon the previous start of the I/O module or recovery from an error.

Display format details (channel details)

The details of a channel error will be displayed as follows:

Table H3.1.1-2 Cause of the channel error

Display item	Description
Channel status (*1)	The current channel status will be displayed. If the I/O module is dual-redundantly configured, the channel status on the control side module will be displayed. - (When the channel is not in use) / Normal / IOP+ / IOP- / TRNS+ / TRNS-/OvrRange/Ch Fail
Latest channel error (*1)	This part displays the time that the channel recovered from the error and the latest error information. If the I/O module is dual-redundantly configured, the latest error on the control side module will be displayed. This item is displayed only when the channel status is normal. Example: Normal (21/6/2005 12:50:56 Last Error: IOP+)
Cause of the channel error detected by the input/output module(*2)	The last-saved channel error in the I/O module will be displayed. If multiple errors are kept in the I/O module, the multiple errors may be displayed. Even if the I/O module is in dual-redundant configuration, the error of the module will be displayed anyway. Example : Open Circuit (0x0401 5561) Short Circuit (0x0401 5562)

*1: The channel status during IOM Failure is the status right before the IOM fails.
*2: If the IOM failure is caused by the abnormality of a channel, the error of the channel will be displayed in IOM Report.

Example 1: Channel Failed
1: IOP+
2: Ch Fail
Open Circuit (0x0401 5561)

Example 2: Channel Recovered
3: Normal (22/8/2011 12:50:56 Last Error :IOP+)
4: Normal (22/8/2011 12:50:56 Last Error :Ch Fail)
Open Circuit (0x0401 5561)

TIP

The channel status and the last error of a pair of dual-redundantly configured input/output modules will be collected from the active input/output module. If the input/output module is placed in a redundant configuration, read the descriptions regarding the IOM Report of the active input/output module for details.

H3.1.2 Display format for the IOM report of N-IO

The section explains the IOM Reports in the N-IO hardware for N-ESB bus coupler module, N-ESB bus module, and I/O module.

N-ESB bus coupler module (S2EN40x)

The IOM report of S2EN402 and S2EN404 is displayed in the following format.

```
YYYY/MM/DD  HH:MM:SS
(Status)
Bus Coupler Module:
Node            : 2
Slot            : 1
Type            : S2EN404
IOM Model       : S2EN404
FPGA Revision   : 01

(Current Status)
Port1 Status    : Link Up
Port2 Status    : Link Up
Port3 Status    : Link Up
Port4 Status    : Link Up

Port 1 Live List  :  1,  2,  3,  4,  5,  6,  7,  8,  9, 10, 11, 12, 13, 14, 15, 16
Port 2 Live List  : 17, 18, 19, 20, 21, 22, 23, 24
Port 3 Live List  : 25, 26, 27, 28, 29, 30
Port 4 Live List  : 31, 32

(256 byte dump display)
```

Table H3.1.2-1 Display items of S2EN40x

Item	Description
YYYY/MM/DD HH:MM:SS	Date and time when the IOM Report is displayed
Status	Acquisition status of the IOM Report (*1)
Type	Module type: Bus Coupler Module
Node	Node number
Slot	Slot number: 1 to 8
Type	Model of the module: Model of the module defined in SENG
IOM Model	Manufacturing information of the module Model of the module that is installed
FPGA Revision	Revision of FPGA (Field Programmable Gate Array)
Current status	The IOM status is displayed. IOM Normal: Normal IOM Fail: Failure
Port n Status	Link status of N-ESB port n (n=1 to 4) Link Up: Transmission possible Link Down: Communication not possible (*2)
Port n Live List	Live list information of the N-IO node that is connected under the N-ESB port n (n=1 to 4) Addresses of N-IO nodes that support the communication from S2EN40x are listed Scope: 1 to 32, ascending order, maximum 16 nodes; addresses that are not in succession are displayed close to each other. (*3)

*1: Blank when it is normal.
- When implementing a module different from the defined module: This IOM differs from the model name which the engineering function defined.

- When module cannot be accessed: Cannot get the memory information in this IOM.

*2: In S2EN402, Link Down is always displayed for port 3 and port 4.
*3: In S2EN402, no node address is displayed for port 3 and port 4.

N-ESB bus module (S2EN501)

The IOM report of S2EN501 is displayed in the following format.

```
YYYY/MM/DD  HH:MM:SS
(Status)
Node Interface Unit:
Node          : 2
Slot          : Left
Type          : S2EN501
IOM Model     : S2EN501-S00030
FPGA Revision : 8033
Serial No.    : xxxxxxx

(Current Status)
Maintenance Port : Enabled
PSU 1 Status     : Normal
PSU 2 Status     : Fail  (OVERVOLTAGE:  25.1V)
Temperature      : Normal  (24C)
External Equipment:  Normal

(256 byte dump display)
```

Table H3.1.2-2 Display items of S2EN501

Item	Description
YYYY/MM/DD HH:MM:SS	Date and time when the IOM Report is displayed
Status	Acquisition status of the IOM Report (*1)
Type	Module type: Node Interface Unit
Node	Node number
Slot	Slot number: Left or Right
Type	Model of the module: Model of the module defined in SENG
IOM Model	Manufacturing information of the module Model and basic specification code of the module that is installed
FPGA Revision	Revision of FPGA (Field Programmable Gate Array)
Serial No.	Serial No. : Serial No. of the module that is actually installed.
Current status	Displays the status of NIU. NIU Normal: Normal NIU Fail: Failure NIU Fail (Due to maintenance of one module): Failure due to maintenance of one module (*2) NIU Maintenance: Under maintenance
Maintenance Port	Displays the status of the maintenance port Disabled: Inactive Enabled: Active
PSU 1 Status	The status of PSU 1 Normal: Normal Fail: Failure The results of the power diagnosis and voltage value are shown in (). POWER OFF: Stops PSU function OVERVOLTAGE: PSU output shows over-voltage CODE = XXXX: Error with code XXXX has occurred

Continues on the next page

Table H3.1.2-2 Display items of S2EN501 (Table continued)

Item	Description
PSU 2 Status	The status of PSU 2 Redundant power: same as PSU 1
Temperature	Temperature around S2EN501 Normal: Normal HI: HI alarm LO: LO alarm Temperature (Celsius) is shown in ().
External Equipment	The status of the discrete input from external devices Normal: Normal Fail: Failure

*1: Same as S2EN40x.
*2: This status indicates that one module of the NIU is normal and the other is under maintenance.

N-IO I/O module (example for S2MMM843)

The IOM report is displayed in the following format.

```
YYYY/MM/DD  HH:MM:SS
(Status)
I/O Module:
Node                : 2
Unit                : 1
Slot                : 1
IOM Type            : S2MMM843
IOM Model           : S2MMM843-SS1030S1U000000
Serial No.          : xxxxxxx
Base Plate Type     : S2BN1D
Base Plate Model    : S2BN1D

F-SB Status
  Bus          S2EN501        Status
  1            L              Normal
  1            R              Normal
  2            L              Normal
  2            R              Normal

(Current status) : (Current error (CPU detection))
      First Error Code : (First error)
      Last Error Code : (Error at recovery)
      (Error information in IOM)

Channel
       1 : (Channel type)
          (Channel Status) (Cause of Last Error)
                    (History of Error Cause in IOM)
        (Skip)
       16 : (Channel type)
            (Channel Status) (Cause of Last Error)
                    (History of Error Cause in IOM)
(6k byte dump display)
```

Table H3.1.2-3 Display Items of the N-IO I/O Module

Item	Details	Description
YYYY/MM/DD HH:MM:SS		Date and time when the IOM Report is displayed
Status		Acquisition status of the IOM Report (*1)

Continues on the next page

Table H3.1.2-3 Display Items of the N-IO I/O Module (Table continued)

Item	Details	Description
Type		Module type: I/O Module
Node		Node number
Unit		I/O Unit number: 1 to 6
Slot		Slot number: 1 to 2
Type		Model of the module: Model of the module defined in SENG
IOM Model		Manufacturing information and firmware revision of the module Model, basic specification code, hardware revision, and firmware revision of the module that is installed
Serial No.		Serial No. : Serial No. of the module that is actually installed.
Base Plate Type		Model of the base plate: Model of the base plate defined in SENG
Base Plate Model		Model of the base plate: Model of the base plate that is installed (*2)
F-SB Status	IN-Bus	Flexible-SB bus number seen from IOM (1, 2): 1 or 2
	S2EN501	Slot position of S2EN501: L (left) or R (right)
	Status	Communication status between S2EN501 and IOM Normal: Normal Fail: Failure
(Main cause of error in IOM)	Current status	Displays the current status of IOM. IOM Normal: Normal IOM Fail: Failure IOM Fail (Output Shutoff): Error in output shutoff switch operation
	Current error details	Displays the current cause of the IOM error that is detected by the CPU in character strings and error code. Displayed when there is an error in IOM. Example: No response (0x0000 5101)
	First Error (*3)	Displays the first error code detected by the CPU in character strings, error code, and time (time of error occurrence). First error indicates the change of IOM status from normal to error. It appears when an error occurs even once. Example: 2016/2/24 12:34:56 IOM Fail (HRDY OFF) (0x0000 5105)
	Last Error (*3)	Displays date and time of recovery, last error code and startup cause. Displays in the normal state of IOM after recovery from error. Example: 2016/2/24 12:50:56 IOM Restart (0x0000 5106)
	Information of errors within the IOM (*4) (*5)	Displays the IOM internal error code and startup cause. This is displayed when IOM information is obtained and the error cause is stored. Example 1: IOM in normal state IOM Normal: IOM Restart (Power On) (0x0301 5547) Example 2: IOM in error state IOM Fail: IOM Readback Error (0x0101 5502)

Continues on the next page

Table H3.1.2-3 Display Items of the N-IO I/O Module (Table continued)

Item	Details	Description
Channel		Displays the following information for each channel. The number of channels depends on the IOM type. S2MMM843, S2MDV843: 1 to 16 channels
	Channel type	Displays the signal type of the I/O channel defined in IOM Builder.
	Channel status (*6) (*7)	Displays the current channel status. If IOM is redundant, channel status of the control side is displayed. - (Unused) / Normal / IOP+ / IOP- / TRNS+ / TRNS- / Rang Over / Ch Fail, etc.
	Cause of Last Error (*6)	Displays date and time of recovery from channel error, and cause of the last error. . If IOM is redundant, cause of the last error that has occurred in the module of the control side is displayed. It is displayed only when the channel is normal. Example: Normal (2015/6/21 12:50:56 Last Error: IOP+)
	Display of history of IOM error causes (*7)	Cause of the last error saved in IOM is displayed (if there are multiple errors, they are individually displayed). Even when IOM is redundant, error cause (cause of error detected in the corresponding module) of the corresponding module is displayed. Example 1: Open Circuit (0x0401 5561) Example 2: Short Circuit (0x0401 5562)

*1: Same as S2EN40x.
*2: In the base plate for intrinsic safety barrier, the basic specification code (-xxxC/ -xxxD) is displayed at the end of base plate model. Only a character (4th character = position of terminal) is displayed according to the base plate while others are displayed as xxx.
*3: The current status of IOM and display pattern of First Error/Last Error are similar to SSC60 FIO.
*4: The "Information of errors within the IOM" lists the details of factors of the "Current status" that are due to the I/O module. The status information for individual channels is not included here.
*5: The "starting factors" displayed in the "Information of errors within the IOM" are detailed factors upon the previous start of the I/O module or recovery from an error.
*6: The status before the error occurrence is retained during the IOM error occurrence.
*7: When the "Channel status" is Normal, this indicates that the "Display of history of IOM error causes" is a history of errors from the past. The channel status can be confirmed from the SCS State Management Window and HIS due to being notified to the operating status and system alarm.

SEE ALSO For more information about signal types of the channels, refer to:

"● Lower part of the list view when an individual I/O module of an N-IO node is selected" on page H1-20

For more information about IOM error causes, channel status, and details displayed in history of errors, refer to:

H3.1.3, "Code system for causes of errors in the IOM Report" on page H3-12

● High current output

The IOM report is displayed in the following format when the signal type of the channel is set to high current output with S2MMM843 or S2MDV843.

```
Channel
    1 : (OUT) Status 2.0A*
        Ch Fail
    2 : (OUT) Status 2.0A
        -
    3 : (OUT) Status 2.0A
        -
                Open Circuit (0x0401 5561)
```

This section describes the IOM Report when there is an error in the non-primary channel.

Channel error information is displayed in the part that shows the channel status of the IOM report. For example, if failure occurs in non-primary channel 3 of combined 1 to 3 channels,

information is displayed in both the primary channel of the IOM report and the non-primary channel where error occurred.

When the high current output is set, “Cause of last error” of the primary channel indicates the compound causes of the primary channel and non-primary channel. When the high current output is set, check the “Cause of last error” of the primary channel.

“Channel status” is displayed in the primary channel. “Cause of last error” is also displayed if error occurred in the past. Actual error cause is displayed in “Error cause history of IOM” in the non-primary channel. However, "-" is displayed in “channel status” to indicated that the channel is not used.

If an error occurs only in the primary channel, information is displayed only in the number of the primary channel.

Table H3.1.2-4 Display items of high current output

Signal type	Character string	Description
Status output (1.3A output)	(OUT) Status 1.3A*	Primary channel
	(OUT) Status 1.3A	Non-primary channel
Status output (2A output)	(OUT) Status 2.0A*	Primary channel
	(OUT) Status 2.0A	Non-primary channel

The "Display of history of IOM error causes" displays the latest information on the causes of errors that have occurred anytime in the past leading to the present. With the large current output (DO), even in a case when an error has occurred with a certain channel, information of occurrence in the past may be remaining in the error cause history of a different channel that is currently normal.

H3.1.3 Code system for causes of errors in the IOM Report

The display format and the code system in the IOM Report to indicate the causes of errors are as follows:

Display format

Category of input/output module errors Δ Category of causes of errors

Code system for category of Input/Output module errors

- 0x00XX
  Error detected by the CPU
- 0x01XX
  Input/Output Module Hardware Failure
- 0x02XX
  Input/output module setting error (such as a disconnected connector on the field side)
- 0x03XX
  Recovery from an input/output module error (such as when the input/output module was recovered from 0x02 above, or recovered after the fallback operation was executed upon detecting a host side error)
- 0x04XX
  Channel error (In this case, there is an error with the applicable channel. It indicates a wiring error or a channel hardware failure when the input/output module is in a single configuration. If the input/output module is in a redundant configuration, the channel hardware failure will be displayed as the category 0x01XX "Input/output module hardware failure.")

Code system for category of causes of errors

- 0x51XX
  Content of error detected by the CPU
- 0x55XX
  Content of error detected by the input/output module (including cause of recovery)

Cause of the Input/Output module error (CPU detection)

The following explains the details of the codes used to indicate the cause of the input/output module error detected by the CPU. The IOM Report will display these codes as "Current error information (CPU detection)," "Information for first error," or "Error information at recovery."

Table H3.1.3-1 Details of codes for cause of Input/Output module error (CPU detection)

Code (hexadecimal)	Display	Description
0000 5101	No response	A no-response error has occurred during the communication between the CPU and the input/output module. The error occurred is either with the input/output module or in the communication path to the input/output module.
0000 5102	IOM model Code Error	The model name of the input/output module defined in the SENG does not match that of the input/output module installed. Verify the model name of the input/output module.

Continues on the next page

Table H3.1.3-1 Details of codes for cause of Input/Output module error (CPU detection) (Table continued)

Code (hexadecimal)	Display	Description
0000 5103	IOM Configuration Error	The setting information defined in the I/O parameter builder does not match the input/output module setting information. Perform IOM download.
0000 5104	IOM Fail (HRDY OFF)	An input/output module hardware failure has been detected. An error occurred and the HRDY on the I/O module turned OFF. Check the error information inside the input/output module for the detailed cause of the error.
0000 5105	I/O Error (AP READY-OFF)	The error may have been generated because the connector is disconnected and field power not supplied, or IOM download was performed. Check the error information inside the input/output module for the detailed cause of the error.
0000 5106	IOM Restart	The input/output module has recovered from the error state. Check the error information inside the input/output module for the detailed cause of the error.
0000 5107 (*1)	Output Shutoff	An error occurred and the Output Shutoff switch was activated due to a reason other than output module failure (the HRDY does not turn OFF). Check the IOM Report for the detailed cause of the error. If this type of error occurs, perform the output module start operation after the cause of the error has been eliminated.
0000 5111	Communication Error	An error has been detected in the data check of the communication between the CPU and the input/output module. This error may have been caused due to a failure with the input/output module or the communication path between the CPU and the input/output module.
0000 5112		
0000 5113		
0000 5108 (*2)		
0000 5109 (*2)		
0000 511d (*2)		
0000 511e (*2)		
0000 5114	IOM Redundant Control Fail	An error has been detected in the redundancy control part of the I/O module. Replace the I/O module. However, when two I/O modules of single definition are changed to redundant in the FIO node and online change download is performed, this error may occur if the connector is connected only to the I/O module of either side. In this case, you need to connect the connector to the I/O modules of both sides. Recovery can be checked by system alarm message No.0082 "Normal recovery of I/O modules". In this case, it is not necessary to replace the input/output module.
0000 5115		
0000 5116	IOM Error	An error has been detected in the input/output module. Replace the input/output module. However, if the IOM Error (0000 5117) occurred after the IOM downloading or during the SCS restarts after offline downloading, there is no need to replace the input/output module.
0000 5117		

*1: Only SDV531-S13 and L1DV531
*2: N-IO only

Differences in output results as a result of differences in AIO/DIO module firmware

If the following errors occur and an IOM report is displayed, either "0000 5103" or "0000 5105" will be displayed, depending on the version of the AIO/DIO module.

- Download in progress for input/output module initialization
- Front connector disconnected
- Failure in the power supply from the front connector

When an error addressed as “0000 5103” remains unsolved although you perform IOM download as the corrective action against “0000 5103” error, the actual error is possibly one of these three errors because they are originally “0000 5105” errors. Confirm that the front connector is properly connected.

Error information inside the Input/Output module

The following explains the details of the codes for the cause of error detected by the input/output module in the channel common area of the input/output module, or in the channel area if the input/output module is in a redundant configuration. The IOM Report will display these codes as "Error information inside the input/output module."

Input/Output module hardware failure

The following explains the details of the codes for hardware failure in the channel common area of the input/output module, or in the channel area if the input/output module is in a redundant configuration.

Table H3.1.3-2 Details of codes for Input/Output hardware failure

Code (hexadecimal)	Display	Description
01xx 5501 (xx: Internal code)	IOM Channel Common Fail	There has been a failure in the channel common area of the input/output module. Replace the input/output module.
0101 5502 0401 5502 (*1)	Output Readback Error	An error has been detected in the readback process for the output value. Check the field wiring of the analog output module for any abnormality (for example, short-circuits between channels), and also confirm that the total resistance of all connected cables and devices does not exceed the value of the allowable output load resistance for output modules that is written in the GS (General Specification). If the wiring and resistance are appropriate, replace the output module.
0101 5503 0401 5503 (*1) (*2)	Internal Power Supply Fail	An error has been detected in the channel power supply. Replace the input/output module.
0101 5504 0401 5504 (*1)	Output Channel Stuck at ON	A failure that the output channel is unable to change from ON to OFF has been detected. Check the field wiring for any abnormality (for example, short-circuits between channels). If there is no field wiring error, replace the output module.
0101 5505 0401 5505 (*1)	I/O Channel Stuck at OFF	With the input channel, a failure where the input signal does not turn ON has been detected. With the output channel, a failure where the output signal cannot be turned ON has been detected. If there are not errors with the field wiring, replace the I/O module.

Continues on the next page

Table H3.1.3-2 Details of codes for Input/Output hardware failure (Table continued)

Code (hexadecimal)	Display	Description
0101 5506 0401 5506 (*1)	Over Current	An overcurrent failure has been detected inside the input/output module. Replace the input/output module.
01xx 5507 04xx 5507 (xx: Internal code) (*1)	IOM Channel Fail	There have been some errors with the channel area of the input/output module. Check if there is an input of a signal value at a level between ON and OFF or chattering has occurred. If the input signal level is normal or chattering has not occurred, replace the input/output module.

*1: For a channel failure, the error code and the error status will vary depending on whether the I/O module is of a duplex configuration or a single configuration.
- The upper error code is for a redundantly configured I/O module, while the lower error code is for a non-redundantly configured I/O module.
- If the input/output module is in a redundant configuration, this error will be an IOM Fail error. In a non-redundant configuration, the error will occur only to the failed channel.

*2: FIO only

SEE ALSO

For more information about allowable load resistance of the analog output modules for SIL 3, refer to:

ProSafe-RS Analog I/O Modules (for FIO) (GS 32P06K60-01EN)

For more information about allowable load resistance of the analog output modules for SIL 2, refer to:

ProSafe-RS Lite Analog I/O Modules (GS 32P56K30-01EN)

Input/Output module setting error

The following explains the details of the codes for input/output module setting error.

Table H3.1.3-3 Details of codes for Input/Output module setting error

Code (hexadecimal)	Display	Description
0201 5521 (*1)	Connector on Field Side Disconnected	The connector on the field side is disconnected. Check the connector.
0201 5522 (*1)	Field Power Supply Error	There has been a voltage error with the field power supply. Check if there are any errors with the field power supply or the wiring. If there is no error, replace the input/output module.
0201 5523	Execution of Download	IOM download is being executed.
0201 5524 0401 5524 (*1) (*2)	Transmitter Power Error	There has been an error with the transmitter power supply inside the input/output module. Check if there are any errors with the transmitter, the field wiring and the input/output module setting. The error may have been caused because the two-wire/four-wire setting of the current input module and the pin setting of the input/output module do not match.
0201 5525 (*3)	IOM Disabled	The I/O module has been stopped due to a request from a higher level.
0201 5526 (*4)	Base Plate Model Code Error	The model of the base plate for IOM that is defined in the builder and the model of the actually mounted base plate do not match. Check the model of the base plate.
02xx 5542 (xx: Internal code) (*4)	Fallback	The I/O module has detected an error in the communication with the host, and the fallback operation was executed. Check the communication path between the CPU and I/O module.

*1: FIO only
*2: For a channel failure, the error code and the error status will vary depending on whether the I/O module is of a duplex configuration or a single configuration.

- The upper error code is for a redundantly configured I/O module, while the lower error code is for a non-redundantly configured I/O module.
- If the input/output module is in a redundant configuration, this error will be an IOM Fail error. In a non-redundant configuration, the error will occur only to the failed channel.

*3: Only style S4 or later of SAI143 and L1AI143
*4: N-IO only

Recovery from Input/Output module error

The following explains the details of the codes for recovery from input/output module error.

Table H3.1.3-4 Details of codes for recovery from Input/Output module error

Code (hexadecimal)	Display	Description
0301 5541 (*1)	Connector on Field Side Recover	The input/output module has recovered from the disconnection error of the field side connector.
03xx 5542 (xx: Internal code)	Fallback	The I/O module has recovered from fallback.
0301 5543	Field Power Supply Recover	The field power supply has recovered to a normal state.
0301 5544	Download Completed	IOM download has been completed.
0301 5545 (*2)	IOM Enabled	The I/O module has recovered from being stopped due to a request from a higher level.
0301 5546 (*1)	Output Shutoff	The output shutoff switch has recovered from operation. Follow the recovery procedures.
0301 5547	IOM Restart (Power-On)	The input/output module started after turning the power on.
0301 5548 (*1)	Transmitter Power Recover	The transmitter power supply has recovered to a normal state.

*1: FIO only
*2: Only style S4 or later of SAI143 and L1AI143

Cause of the channel error

The following explains the details of the codes related to channel error. The IOM Report will display these codes as "Channel status", "The latest channel error" and "Cause of the channel error detected by the input/output module" in the area where causes of channel errors are to be displayed.

Channel status, the latest channel error

"Channel status" in the IOM Report will display the channel status (cause of a channel error) detected by the CPU. The "latest channel error" is the last error that CPU detected. The details of the codes are explained in the following table.

Table H3.1.3-5 Details of codes for channel status

Code (hexadecimal)	Display	Description
0000 5121	TRNS+	A transmitter high limit error has occurred.
0000 5122	TRNS-	A transmitter low limit error has occurred.
0000 5123	IOP+	An input high limit error has occurred.
0000 5124	IOP-	An input low limit error has occurred.

Continues on the next page

Table H3.1.3-5 Details of codes for channel status (Table continued)

Code (hexadecimal)	Display	Description
0000 5125 0000 5126	OvrRange	Replace the input module. • For SAI143/L1AI143 and SAV144/L1AV144 There has been an internal error that the analog input value is out of the range between -25 % and 125 %. • For SAT145/L1AT145 and SAR145/L1AR145 There has been an internal error that the input value is either not a number, an infinity or out of the range that the module can handle.
0000 5127	Ch Fail	A channel error has occurred. Check the display of cause of the channel error detected by the input/output module for the cause of the error.
0000 5128 (*1)	IS Barrier Disconnected	Disconnection of intrinsic safety barrier has been detected. Check the connection of intrinsic safety barrier.
0000 5129 (*1)	IS Barrier Configuration Error	Setting error of intrinsic safety barrier has occurred. Settings information defined in the builder and the connected intrinsic safety barrier may be different.
0000 512a (*1)	Open Circuit	An error has occurred due to open circuit. Check the field wiring. A short circuit error is suspected if a barrier is used.
0000 512b (*1)	Short Circuit	An error has occurred due to short circuit. Check the field wiring.
0000 512c (*1)	Field Side Error	Other errors (open circuit/short circuit detection by intrinsic safety barrier, etc.) have been detected on the field side. Check the error cause in detailed cause.

*1: N-IO only

Cause of channel error detected by the Input/Output module (Input/Output module detection and the details of channel error)

"Cause of channel error detected by the input/output module" will display channel errors detected by the input/output module. Details of the codes are explained.

Table H3.1.3-6 Details of codes for cause of channel error detected by the Input/Output module

Code (hexadecimal)	Display	Description
0401 5561	Open Circuit	An error has occurred due to open circuit. Check the field wiring. In SDV526/L1DV526, open circuit occurs due to a channel fuse burnout caused by a short circuit. Check the field wiring and channel fuses.
0401 5562	Short Circuit	An error has occurred due to short circuit. Check the field wiring.
0401 5563 (*1)	Short circuit between channels	There is short circuiting between channels. Check if there are any field wiring errors.
0401 5564 (*1)	Output Overload	An output overload has been detected. Check if there are any errors with the field wiring or the loading device.
0401 5567 (*1)	RJC Error	This is an input error of reference junction compensation (RJC) in SAT145/L1AT145. The cause is likely a failure in the thermistor for the reference junction compensation for the terminal board. Check if there are any errors in the terminal board.
0401 5568 (*1)		
0401 5522 (*2)	Field Power Supply Error	There has been a voltage error with the field power supply. Check the field power supply and wiring.

Continues on the next page

Table H3.1.3-6 Details of codes for cause of channel error detected by the Input/Output module (Table continued)

Code (hexadecimal)	Display	Description
0401 5570 (*2)	DO Shutoff	Detected an error that activated the DO shutoff switch in the DO channel of S2MMM843 or S2MDV843. Check the error cause of the DO channel in IOM.
0401 5571 (*2)	I/O Shutoff	Detected an error that activated the I/O shutoff switch in the AO channel of S2MMM843. Check the error cause of the AO channel in IOM.
0401 5572 (*2)	Line Fault Detection	Open circuit or short circuit is detected in the intrinsic safety barrier. Check the field wiring.
0401 5573 (*2)	IS Barrier Configuration Error	Setting error of intrinsic safety barrier has occurred. Settings information defined in the builder and the connected intrinsic safety barrier may be different.
0401 5576 (*2)	IS Barrier Disconnected	Disconnection of intrinsic safety barrier has been detected. Check the connection of intrinsic safety barrier.

*1: FIO only
*2: N-IO only

If the status of the input/output module is single, the code 04xx xxxx error explained on the Input/output module hardware failure page is displayed as the cause of the channel error detected in the input/output module.

SEE ALSO For more information about causes of channel errors, refer to:

"● Input/Output module hardware failure" on page H3-14

H3.2 IOM Report of communication modules

This section explains the IOM Report on the following communication modules.

- Serial communication module (Modbus slave communication)
- Serial communication module (Subsystem communication)
- Ethernet communication module (Modbus slave communication or DNP3 communication)
- Ethernet communication module (Subsystem communication)
- Fire and gas communication modules (Fire and gas communication)

Display format of IOM Reports on serial communication modules (Modbus slave communication)

The display format of IOM Reports when an ALR111 or ALR121 is used for Modbus slave communication is as follows:

I/O Module:

Node:	2
Slot:	6
Type:	ALR111
IOM Model:	ALR111-S03 S0U0H0-- F0--

(4-kbyte dump display)

Display format of IOM Reports on serial communication modules (subsystem communication)

The display format of IOM Reports when an ALR111 or ALR121 is used for subsystem communication is as follows.

TIP Information of the specified communication module is displayed even when the module is configured as a redundant module.

```
I/O Module:
Node:        2
Slot:        4
Type:        ALR111
IOM Model:   ALR111-S03 S0U0H0-- F0--
Serial No:   XXXXXXXX

Subsystem Name:    (Subsystem name)
Revision:          (Subsystem package revision)

IOM Status:        (Communication module status) (Detail cause)
Port1 Status:      (Port communication status)
Port2 Status:      (Port communication status)

Communication Status
1     0000  0000  0000  0000  0000  0000  0000  0000  0000  0000
11    0000  A3B0  A3B0  A3B0  0000  0001  0001  0001  0001  0001
                .
                .
(4-kbyte dump display)
```

In the above example, communication definitions 1 to 11 indicate a normal status, while communication definitions 12 to 14 indicate an A3B0 error. After the communication definition 16, there is no communication definition or corresponding communication is not performed.

Table H3.2-1 Display items for ALR111/ALR121 in subsystem communication

Display item	Description	Remark
Subsystem name	The name of the subsystem package currently loaded to the ALR111/ALR121 is displayed. (Example) Subsystem Name: S_MODBUS	-
Subsystem package release number	The release number of the subsystem package in the ALR111/ALR121 is displayed.	-
Detailed causes of communication module statuses	The status of the communication module is displayed. • Control: Normal (at single configuration), control side in the case of a redundant module • Stand-by: Stand-by side in the case of a redundant module • Fail: Error If the module status is "Fail," the detail cause of the error (error cause code) is displayed.	Refer to the Diagnostic information message No. 0081 for the content of the error cause code.
Port 1/2 communication statuses	Displays the port status of port 1 and port 2. "Ready" is displayed in the case of communication module error. • Ready: The serial communication status is normal, or there is no communication definition. • Error: A serial communication error has occurred.	-
Communication Status (Communication error code for communication definition n: 1 <= n <= 128)	The communication status is displayed for each communication definition. This item is invalid if the communication module has generated an error. The status information for 128 definitions is displayed. 0x0000: The communication status is normal. 0x0001: There is no communication definition, or communication is not performed. 0xA3XX: Communication error code	-

Table H3.2-1 Display items for ALR111/ALR121 in subsystem communication (Table continued)

Display item	Description	Remark
Communication Status (for SLSEVENT type communication definition when subsystem communication program S_SLSMOD is used in ALR121)	The area for two definitions is required for SLSEVENT type communication definition for ProSafe-SLS event collection. 0x0000 0x0000: The communication status is normal. 0x0001 0x0000: Communication is not performed. 0xA3XX 0x0000: Communication error code	-

SEE ALSO

For more information about Diagnostic information messages, refer to:

Message Number 0081 in 3.1, "Safety Control Station Error Occurrence and Recovery Messages (Message Numbers 0001 through 0094)" in Messages Reference Manual (IM 32P02B10-01EN)

For more information about communication error codes displayed under Communication Status, refer to:

- manual for the connected Modbus system
- "■ Communication error code" in D2.1, "Communication specifications" in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

Reading communication status when using ProSafe-SLS communication function

When ALR121 is used for ProSafe-SLS communication function, communication status may be read in a particular way. Communication status for SLSEVENT type communication definition for ProSafe-SLS event collection is displayed in 4-kbyte that is equal to two definitions of other type. The detailed example is as follows:

Communication definition of SLSEVENT type

Communication Status										
1	0000	0000	0000	0000	0000	0000	0000	0000	0000	0000
11	0000	A3B0	A3B0	A3B0	0000	0001	0001	0001	0001	0000
21	0000	0000	0000	0000	0000	0000	0000	0000	0000	0000

.
.

(4-kbyte dump display)

The circled 14th communication definition is SLSEVENT type and other communication definitions are types other than SLSEVENT type. Each communication definition corresponds to the following communication status:

Table H3.2-2 Correspondence between communication definition and communication status

Communication definition	Communication status
1st to 11th	Normal communication
12th to 13th	Communication error (No response from subsystem)
14th	Communication error in SLSEVENT type (No response from subsystem)
15th to 18th	No communication
19th to 29th	Normal communication

Confirm the correspondence relation between each communication definition and communication status on the Comm. I/O Definition tab of Communication I/O Builder or the Communication Group Definition list of Safety Communication I/O Editor.

Display format of IOM Reports on Ethernet communication modules (Modbus slave communication or DNP3 communication)

The display format of IOM Reports when an ALE111 is used for Modbus slave communication or DNP3 communication is as follows:

I/O Module:

Node: 2
Slot: 1
Type: ALE111
IOM Model: ALE111-S03 S0U0H0-- F0--
Serial No: XXXXXXXX

(4-kbyte dump display)

Display format of Ethernet communication module (Subsystem communication) IOM report

The following shows the display format of the IOM report if ALE111 is used for subsystem communication.

TIP Information of the specified communication module is displayed even in the case of redundancy.

```
I/O Module :
Node       : 2
Slot       : 1
Type       : ALE111
IOM Model  : ALE111-S03 S0U0H0-- F0--
Serial No  : XXXXXXXX

Subsystem Name : (Subsystem name)
Revision   :     (Subsystem package revision)

IOM Status :     (Communication module status) (Detail cause)
Port Status :    (Port communication status)

Communication Status
     1  0000 0000 0000 0000 0000   0000 0000 0000 0000 0000
    11  0000 A3B0 A3B0 A3B0 0000   0001 0001 0001 0001 0001
        :

(4-kbyte dump display)
```

In this example, communication definition from 1 to 11 shows “normal”, 12 to 14 shows "A3B0 error" and 16 onwards shows "Communication is not performed”.

Table H3.2-3 ALE111 display items for subsystem communication

Display items	Display contents	Remarks
Subsystem name	Displays the name of the subsystem package that is loaded in ALE111. (Example) Subsystem Name: S_MODTCP	
Subsystem package revision	Displays the package revision of the subsystem in ALE111. (Example) Revision: R4.01.00	

Continues on the next page

Table H3.2-3 ALE111 display items for subsystem communication (Table continued)

Display items	Display contents	Remarks
IOM status Detailed cause	The IOM status is displayed. Control: Normal status of non-redundant module, or control side of redundant modules Stand-by: Standby side of redundant modules Fail: Failure Detailed causes (error code) of the error are displayed in the case of "Fail".	Refer to System Alarm Message No.0081 for contents of error cause code.
Port status	The communication status of the port is displayed. Note that “Ready” is displayed in the case of IOM error. Ready: Communication is normal or undefined Error: Communication error has occurred	
Communication error code for each communication definition	The communication status for each communication definition is displayed. Not valid in the case of IOM error. Displays for 128 definitions. 0x0000: Normal communication 0x0001: Undefined communication or no communication 0xA3XX: Communication error code	

Display format for the IOM Report of fire and gas communication modules

The display format for the IOM Report of S2LP131 is as follows:

```
I/O Module  :
Node              : 2
Slot              : 1
Type              : S2LP131
IOM Model         : S2LP131-S01 S0U0H0--F0--
Serial No         : xxxxxxxx

Subsystem Name    : (Subsystem package name)
Revision          : (Subsystem package revision)

IOM Status        : (Communication module status) (Detail cause)
Port Status       : (Port communication status)

Communication Status
Number      Communication Group     SS-SCPATH    SS-SCOM
1           GS01-001 PV             0000         0000
2           GS01-001 DIAGSTATUS     0000
:
101         GS01-50 PV              0000         0000
102         GS01-50 DIAGSTATUS      0000
:
200

(14-kbyte dump display)
```

Table H3.2-4 Display items of S2LP131

Display item	Description	Remarks
Subsystem package name	Displays the name of the subsystem package that is loaded in S2LP131. (Example) Subsystem Name: S_FGCOM	
Subsystem package revision	Displays the revision of the subsystem package in S2LP131. (Example) Revision: R1.01.00	

Continues on the next page

Table H3.2-4 Display items of S2LP131 (Table continued)

Display item	Description	Remarks
IOM status Detailed cause	The IOM status is displayed. Control: Normal Fail: Error Detailed causes (error cause code) of the error are displayed in the case of "Fail".	Refer to System Alarm Message No.4209 and No.4211 for contents of the error cause codes.
Port status	The communication status of the port is displayed. Note that “Ready” is displayed in the case of IOM Fail. However, “Error” is displayed when an SS-SCOM error has occurred. Ready: Communication is normal or undefined Error: Communication error has occurred	
Communication error code for each communication definition	The communication status for each communication definition is displayed. Invalid in the case of an IOM error. Displays codes for 200 definitions. 0x0000: Normal communication 0x0001: No communication (*1) 0xA3XX: Communication error code (SS-SCPATH) 0x5AXX: Communication error code (SS-SCOM) Blank: There is no corresponding data. (*2)	

*1: This error code will not be displayed for SS-SCOM. PROFIsafe communication between SCS and GS01 does not have a status indicating that communication is not completed. Therefore, in the case of SS-SCOM, either 0x0000, which indicates normal communication, or 0x5AXX, which indicates a communication error, is displayed.
*2: The SS-SCOM column is blank for non-safety data.

SEE ALSO

For more information about Diagnostic information messages, refer to:

- Message Number 4209 in 2.1, “System Alarms (Message Numbers 4101 through 4222)” in Messages Reference Manual (IM 32P02B10-01EN)
- Message Number 4211 in 2.1, “System Alarms (Message Numbers 4101 through 4222)” in Messages Reference Manual (IM 32P02B10-01EN)

H4. Displaying I/O channel status

The I/O Channel Status dialog box displays the states of channels of all input/output modules of the relevant SCS in the list format.

Channels whose output is disabled can be changed to the output enabled condition as long as the status is normal, by clicking the [Output enabled] button in this dialog box. Once output channels are placed in the output enabled condition, the output values of the application logic are output to the field.

I/O Channel Status dialog box

On the tool bar of the SCS State Management window, click [I/O Channel Status]. The I/O Channel Status dialog box appears. If both N-IO I/O modules and FIO I/O modules are installed in SCSP3, their respective status is displayed in the [N-IO] tab and the [FIO] tab.

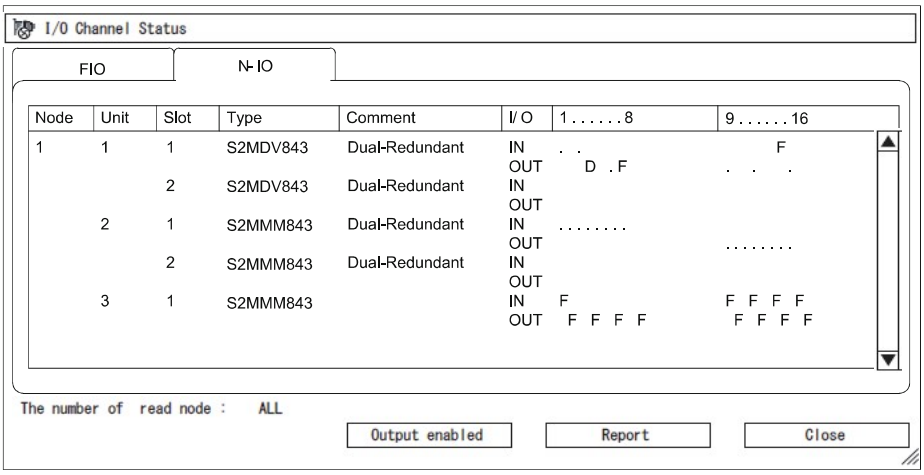

Figure H4-1 I/O Channel Status dialog box

Display of I/O Channel status

Table H4-1 Display of I/O Channel status

Status	Character	Display color
Normal	.	
Error	F	Red
Output Disabled	D	Blue

The error status indicates that the single channel is faulty and/or the error that activates the Output Shutoff switch inside the output module has occurred.

The output disable status indicates that the channel is normal but the output value from the application logic is not sent to the field.

If the I/O module has redundant configuration, the channel status of the control side is displayed in the odd number slot, irrespective of the control status during operation. The channels on the even-number slot are displayed as blank. If the I/O module has redundant configuration, Dual-Redundant is displayed in the Comment column.

The status of the primary channel is displayed, if multiple channels are combined in N-IO I/O module for high current output.

The number of read node configuration information is displayed in the status bar. ALL shows that configuration information of all the nodes is read.

Precautions for forcing functions

Use the following buttons to perform operations in the dialog box.

Table H4-2 Explanation of button names and operations

Button	Description
Output enabled	Place all channels whose outputs have been disabled in the output enabled state within the station.
Report	Displays the same contents of the I/O Channel Status dialog box in the report dialog box.
Close	Close the I/O Channel Status dialog box.

SEE ALSO For more information about enabling output, refer to:

C8., “Output enable operation” on page C8-1

H5. Displaying SCS diagnostic information

SCS diagnostic information messages can be checked in the Diagnostic Information window. The Diagnostic Information window displays diagnostic information messages maintained by the SCS. Diagnostic information messages are the notifications to the users regarding the diagnosis as well as the required necessary actions and maintenance records. From these diagnostic information messages, the location where the error occurred, the cause of the error, the degree of risk, etc., can be identified.

The engineers check the diagnostic information messages for hardware errors, communication errors, etc., in the safety system, and can examine the error causes by referencing the diagnostic information message help function.

Usage of SCS diagnostic information is described below.

Analysis of causes

The Diagnostic Information window allows the user to check diagnostic information messages generated by the SCS' diagnostic function to obtain information on how to handle errors from the Help function. In this way, they are helpful in analysis of causes and maintenance operations.

Classifying potential risks

Each Diagnostic information message has an alarm class that is determined by an error condition, the importance of devices, etc. An engineer can classify the degree of potential risk of the current situation.

Acknowledgement of diagnostic information

Diagnostic information messages maintained by the SCS can be acknowledged and deleted in the Diagnostic Information window.

H5.1 Diagnostic Information window

The Diagnostic Information window displays diagnostic information messages in a list format collected from the SCS.

How to display the Diagnostic Information window

Select a station, I/O node or input/output module, and click [Diagnostic Information] button on the toolbar of the SCS Status Overview window or the SCS State Management window. Only diagnostic information messages related to the selected device are displayed in the Diagnostic Information window.
Up to five Diagnostic Information windows can be displayed at the same time, each window showing the information of an individual station, an input/output module, etc.

Security of the Diagnostic Information window

If you entered the password for the SCS Maintenance Support Tool when launching the original window from which the Diagnostic Information Window was opened, you can perform confirmation and deletion operations. If the original window was displayed in read-only status, the Diagnostic Information window is also opened in read-only status, and operations such as checking and deleting cannot be performed.

H5.2 Diagnostic Information window

The Diagnostic Information window is shown as follows.

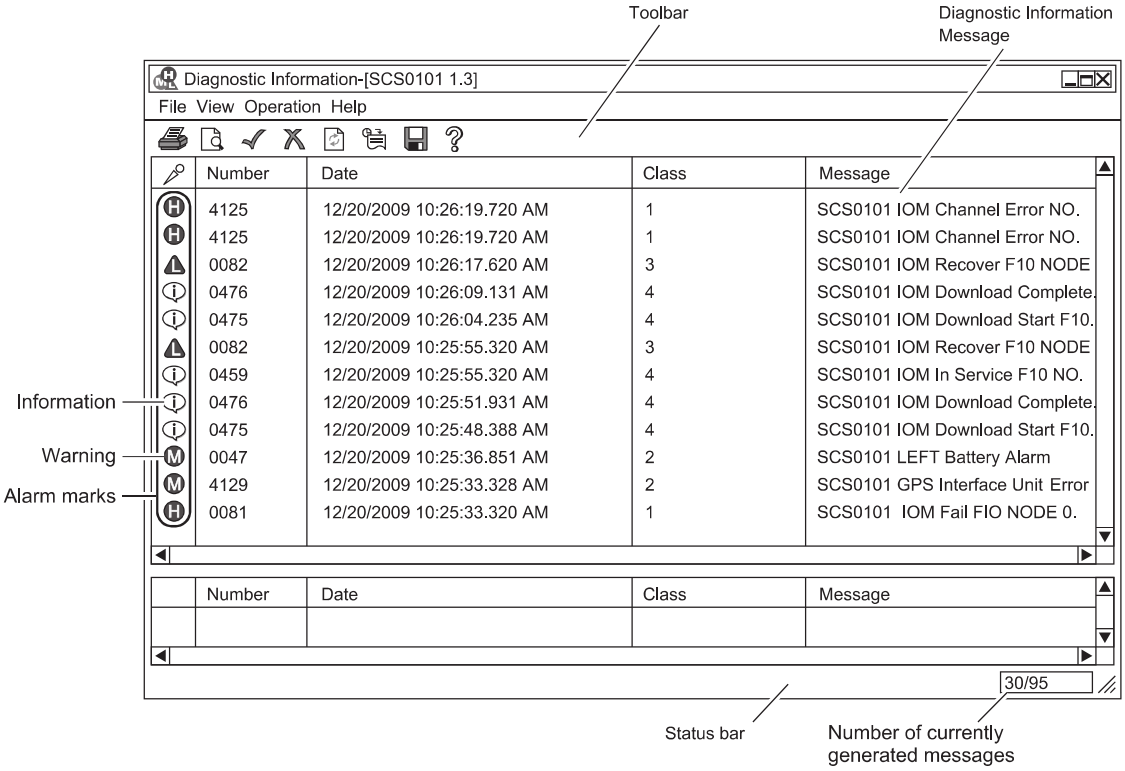

Figure H5.2-1 Diagnostic Information window

The components of the window are explained next.

Toolbar

The following buttons are provided on the toolbar.

Table H5.2-1 Toolbar buttons

Button	Name	Description
	Print	Print diagnostic information messages.
	Print preview	Display print preview.
	Acknowledgement	Acknowledge diagnostic information messages.
	Deletion	Delete diagnostic information messages.
	Update	Update diagnostic information message display.
	Historical	Divide the window and display deleted messages in the lower part (historical display).
	Save	Save diagnostic information messages in CSV format.
	Help	Display help related to the selected diagnostic information message.

Status bar

The status bar shows the number of currently displayed diagnostic information message and the total number of generated messages in the following format:

- Last number of the currently displayed diagnostic information messages/total number of generated diagnostic information messages

Configuration of diagnostic information message

A diagnostic information message consists of the following items.

Table H5.2-2 Items displayed in the Diagnostic Information window

Displayed item	Description
Alarm mark	Mark corresponding to the alarm class
Number	Message number
Time of occurrence	The time when a message occurred
Class	Alarm class determined within an SCS based on the diagnostic status
Message	Diagnostic Information message

IMPORTANT

- With the Diagnostic Information window open and if the number of Diagnostic Information messages of SCS to be displayed exceeds 5000, there are cases where old Diagnostic Information messages remain undeleted. If this occurs, click the [Refresh] button on the tool bar or re-display the Diagnostic Information window.
- Diagnostic Information window shows the messages acquired from the SCS memory by SENG and the messages sent to SENG by the SCS. After the window is displayed, SENG starts acquiring messages from the SCS memory (About 15 messages per second). The messages acquired and sent by the SCS after the window display are listed on top of the list, i.e., the list is not in chronological order. To sort the list based on the time, use the Sort function in the Diagnostic Information window. If you re-display the window after all the Diagnostic Information is collected, the list is displayed in chronological order.

Categories of diagnostic information messages

There are two message categories: warning (including recovery) and information. Diagnostic information messages included in the information category are only notified to the user, for example, they include messages that do not notify recovery messages and messages notifying the number of variables being locked by the forcing function.

Alarm mark display and diagnostic information message display color

The alarm marks attached to diagnostic information messages vary depending on the alarm class: the alarm marks flash as long as the messages have not been acknowledged and remain illuminated once the messages have been acknowledged. The character strings for diagnostic information messages (number, time of occurrence, class and message) are displayed in different colors according to the alarm class. The background color and text color can be specified using Setup Tool.

Table H5.2-3 Message character colors

Alarm mark	Category	Alarm class	Character display color in diagnostic information messages
Ⓗ	Warning	1	Red
Ⓜ	Warning	2	Red
⚠	Warning	3	Green
ⓘ	Information	4	(*1)

*1: The color set as the text color of Setup Tool (the default color is black).

SEE ALSO For more information about setup tool, refer to:

A6.3, “Customization of the SCS Maintenance Support Tool window” in ProSafe-RS User’s Guide (IM 32P01B10-01EN)

Acquisition of diagnostic information messages

Open the Diagnostic Information window to acquire and display one by one from the oldest messages in the SCS.
Messages generated after opening the window are displayed when they are generated.

Updating diagnostic information messages

Click [Update] button on the toolbar of the Diagnostic Information window to refresh information related to diagnostic information messages and diagnostic information status; the information is acquired from the SCS again and the display is refreshed.

Sorting diagnostic information messages

Click one of the columns in the list view of the Diagnostic Information window to sort diagnostic information messages.
If you click a column once, the messages are sorted in the ascending order. If you click once again, the messages are sorted in the descending order.

For example, if you want a list of Diagnostic Information messages in reverse chronological order, click the [Date] column.

Historical display of diagnostic information messages

Clicking [Historical] button on the toolbar of the Diagnostic Information window split the Diagnostic Information window into two parts and the 10 most recently deleted diagnostic information messages will be displayed in the lower part. If you click [Historical] button again, the window split will be released and the display returns to the original.

Outputting diagnostic information messages to external files

Diagnostic information messages can be saved in files in CSV format.

H6. Monitoring by diagnostic information message

SCS sends diagnostic information messages for detected faults and for the operation on the safety functions to notify user of events.

You can confirm the time when a fault occurred and the outline of the cause of the fault by reading the information provided in the diagnostic information message.

Diagnostic information messages can be checked as system alarm on SENG and HIS.

H6.1 Notification of error level through diagnostic information messages

SCS generates a diagnostic information message to notify you that an error has occurred. You can view the diagnostic information messages on the HIS and SENG. However, if a fatal error occurs on an SCS, the CPU of SCS stops; in this case, some diagnostic information messages may not be sent. Diagnostic information messages contain information regarding the level of the error detected on the SCS.

Notification of error level and error status

The status of SCS errors is reported to users through diagnostic information messages. It is also reported to Application logic. The SCS notification process and details for each error level is shown as follows:

Table H6.1-1 Error level types and the error status notification process

Error level	Diagnostic Information Messages	Notification to application logic
Fatal error	Diagnostic information message may not be notified because the CPU stops.	Notification is not possible because the CPU is stopped.
Major error	The failure location, cause of error and other information are notified.	The error and output status is notified.
Minor error	The failure location, cause of error and other information are notified.	A representative error state is notified, instead of an individual error state. An application logic that utilizes this notification can be created.

SEE ALSO For more information about behavior upon the occurrence of an error, refer to:

G2., “Operations and recovery procedures during the SCS error occurrence” on page G2-1

Alarm classes and diagnostic information messages

Failures of devices and SCS operation information are notified to the user as diagnostic information messages. The user can obtain information about the time and location of the error occurrence as well as the error type from the messages.

- The SCS adds information of the alarm class based on the error level when sending a diagnostic information message. The SENG displays messages with color according to the alarm class.

Table H6.1-2 Alarm class

Alarm class	Correspondence with error level	Meaning of alarm class	Example
Class 1 (serious alarm)	Fatal error (*1) Major error	An error that may cause system shutdown occurs and immediate action by the user is required.	Error notification of IOM in single configuration.
Class 2 (minor alarm)	Minor error	Notification that requires prompt action by the user, such as hardware replacement and remedy of user operation mistakes although the functions for safety continue to work	• Notification of a error of an IOM on one side of the redundant configuration • Notification of variable lock status by the forcing function continuing for longer than the specified time • Alarm sent by the HKU

Continues on the next page

Table H6.1-2 Alarm class (Table continued)

Alarm class	Correspondence with error level	Meaning of alarm class	Example
Class 3 (light alarm)	-	Notification of recovery from an error	-
Class 4 (notification alarm)	-	Notification of status other than SCS errors to the user	Notification of change of the security level

*1: Because the CPU stops when a fatal error occurs, the system may fail to generate a diagnostic information message that indicates the error.

- The time displayed in a diagnostic information message is the time when the SCS detected an error. The minimum unit of time is millisecond.
- The time information set for an diagnostic information message has the same high accuracy as the time information set for SOE information.

SEE ALSO For more information about the alarm class added to diagnostic information messages, refer to:

Appendix 1., “Alarm Class” in Messages Reference Manual (IM 32P02B10-01EN)

H6.2 Acknowledging and deleting diagnostic information messages

Diagnostic information messages can be acknowledged and deleted on the toolbar of the Diagnostic Information window. If you acknowledge or delete a message, the information about the operation is written to the SCS.

Messages can be acknowledged/deleted individually or in a batch. The method of acknowledging/deleting messages can be specified using Setup Tool. During the plant operation, acknowledge or delete messages individually.

IMPORTANT

- In the Diagnostic information tab of the Setup tool, if you select [Group] to specify batch acknowledgement or batch deletion, all diagnostic information messages displayed in the screen become the target of the acknowledging/deleting operation. Do not use this setting in normal plant operation. Use it only temporarily when testing, and so on.
- If the data in the NVRAM (nonvolatile RAM) on the CPU module is initialized, or if the CPU module is replaced, be sure to restart the SENG. If not, there are cases where some messages remain unacknowledged or undeleted in the Diagnostic Information window.

SEE ALSO For more information about setup tool, refer to:

A6.3, “Customization of the SCS Maintenance Support Tool window” in ProSafe-RS User’s Guide (IM 32P01B10-01EN)

Operation to acknowledge or delete individual diagnostic information messages

Acknowledging and deleting the individual messages can be performed using the toolbar on the Diagnostic Information window.

Acknowledging individual message

In the Diagnostic Information window, select one diagnostic information message and click the [Acknowledgement] button; the Acknowledgement dialog box appears.
Click the [OK] button in the Acknowledgement dialog box to acknowledge.

The flashing of the alarm mark stops in the Diagnostic Information window.

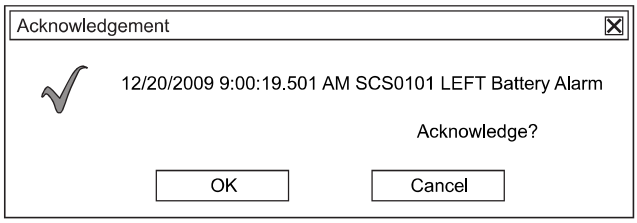

Figure H6.2-1 Acknowledgement dialog box

Deleting individual message

In the Diagnostic Information window, select one acknowledged diagnostic information message and click the [Deletion] button; the Deletion dialog box appears.
Click the [OK] button to delete the diagnostic information message.

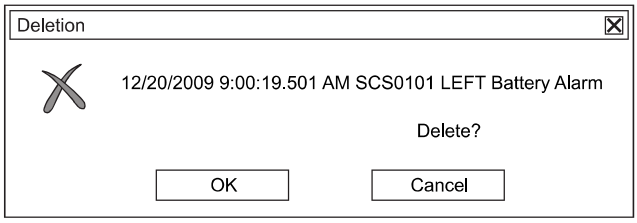

Figure H6.2-2 Deletion dialog box

Operation to acknowledge or delete all diagnostic information messages

To acknowledge or delete all the messages displayed in the screen in a batch, use the Diagnostic Information window.

IMPORTANT

Acknowledge or delete messages individually during normal plant operation; do not acknowledge or delete all messages in a batch.

Acknowledging all messages

Click the [Acknowledgement] button in the Diagnostic Information window; a warning dialog box appears. The warning dialog box appears only one time, when all messages are going to be acknowledged at once for the first time after opening the Diagnostic Information window.
If you click the [OK] button in the warning dialog box, all the diagnostic information messages displayed are acknowledged.

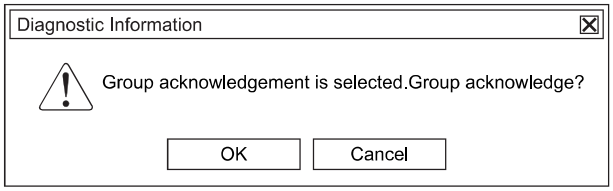

Figure H6.2-3 Warning dialog box displayed when acknowledging all messages

After you click the [Acknowledgement] button, the [Acknowledgement] button and [Deletion] button are disabled for two seconds.

Deleting all messages

Click the [Deletion] button in the Diagnostic Information window; a warning dialog box appears. The warning dialog box appears only one time, when all messages are going to be deleted at once for the first time after opening the Diagnostic Information window.
If you click the [OK] button in the warning dialog box, all the diagnostic information messages displayed and acknowledged are deleted. Diagnostic information messages that have not been acknowledged are not deleted.

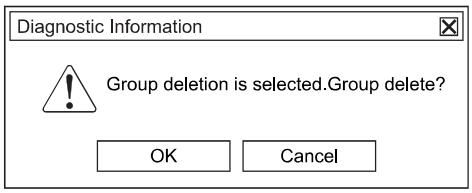

Figure H6.2-4 Warning dialog box displayed when deleting all messages

After you click the [Deletion] button, the [Acknowledgement] button and [Deletion] button are disabled for two seconds.

H6.3 Diagnostic information message help function

The diagnostic information message help function includes of the Help dialog box provided by the system and a user-defined action guide.

Help dialog box

The Help dialog box displays information stored in the Help files related to diagnostic information messages (message number, print example, meaning, cause, and so on) provided by the system.
The Help dialog box can be called in the following manners:

- Select the diagnostic information message in the Diagnostic Information window, and then click [Help] button on the toolbar.
- Double-click the diagnostic information message in the Diagnostic Information window. Help information related to the diagnostic information message you double-clicked is displayed in the Help dialog box.

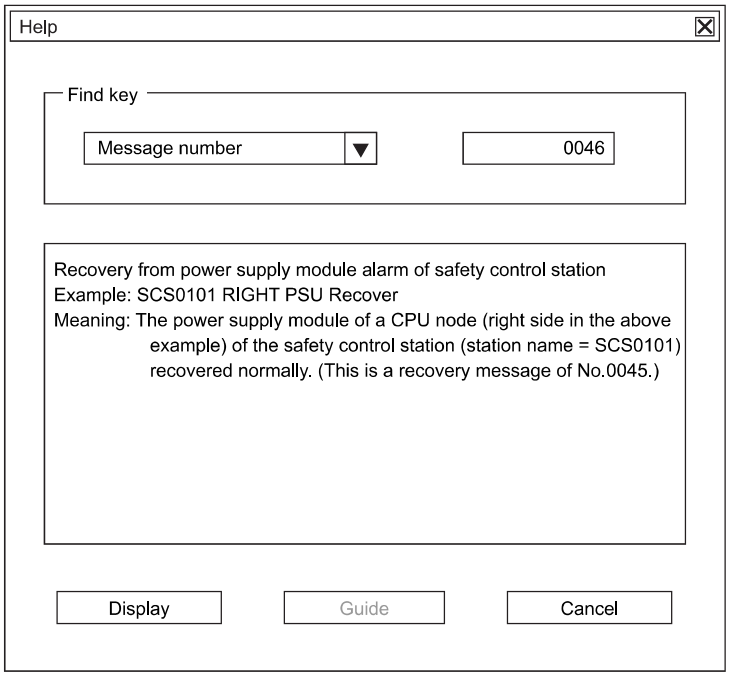

Figure H6.3-1 Help dialog box

- Guide
  The [Guide] button is enabled if a user-defined action guide has been defined. Click the [Guide] button to display the user-defined action guide corresponding to the relevant message number.

User-defined action guide

Engineers can share knowledge, information about actions to be taken, know-how's, etc. about the given situation by describing them in the user-defined action guide. It is also possible to attach images to the user-defined action guide.

Displaying a User-defined action guide

Click the [Guide] button in the Help dialog box to display the User-defined Action Guide.

Creating a User-defined action guide

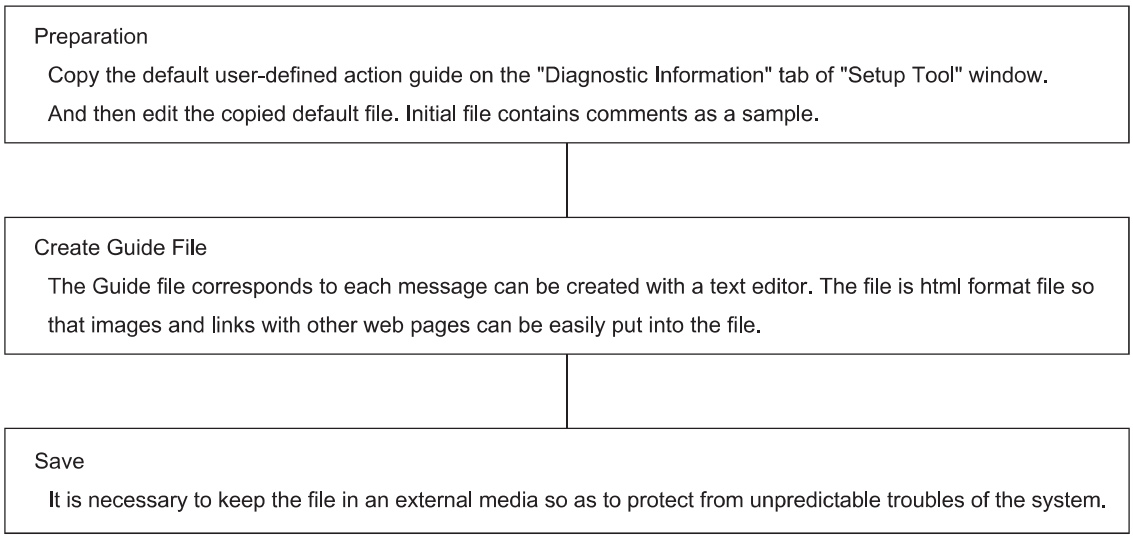

Figure H6.3-2 Create User-defined action guide

To display the file corresponding to the relevant message number by clicking the [Guide] button, it is necessary to label the created guide file with the corresponding message number. For example, (name="@0001") for message number 0001.
An example of a user-defined action guide file is shown as follows.

Table H6.3-1 User-defined action guide file

```
<b><a name="@0001"> Message Number: 1</a></b><BR>
CPU module error<BR>
Action: Replace the CPU module. <BR>
Memo: Please contact Mr. XX. xxx-xxxx-xxx
```

An example of display result of a user-defined action guide file is shown below.

Table H6.3-2 Display result of a User-defined action guide file

```
Message Number: 1
CPU module error
Action: Replace the CPU module.
Memo: Please contact Mr. XX. xxx-xxxx-xxx
```

H6.4 Printing diagnostic information messages

The diagnostic information message displayed in a window can be printed out. Click [Print] on the toolbar of the Diagnostic Information window. The class 1 and 2 alarms are printed out in red and class 3 and 4 alarms are printed out in black.
The information that is printed is described below.

Title

Window name, printing time and page number are printed on the title bar at the top of the page.

Header area

Search condition, message format and description of alarm condition are printed on the first page only.

Message

A printing image of a diagnostic information message is shown as follows.

12/20/2009 2:02:44 PM	page 1/1
Search condition	SCS0101 1.3
Format	Alarm mark,Message number,Date,Class,Message
Alarm mark	New Alarm:No mark,Acknowledged:A,Deleted:D

```

H7. Vnet/IP bus status

This chapter explains how to check the Vnet/IP bus communication status

Overview of Vnet/IP bus status

On the SCS State Management window of the SCS Maintenance Support Tool of SENG, the bus communication status of the SCSs in a domain can be displayed. Using an application logic with the control bus status indicator function block (SYS_NETST) can output the bus error alarm to external alarm lamps for notification.

If integrated with CENTUM system, statuses of all stations of all the domains connected to the Vnet/IP network as well the routing devices among the domains can be displayed. Vnet/IP bus status is displayed in the Network Status Display dialog box of the CENTUM HIS. When the bus status changes, a system alarm message will be generated and output to the HIS.

IMPORTANT

When the network switches are connected in a ring topology, even if one of the cables connecting between the switches is disconnected, the Vnet/IP bus status remain normal and no bus error system alarm will be issued.

To be notified of a ring status, you need to build an FCS application that uses the ring status signals from the network switches.

TIP

For more information about how to build such an FCS application, contact YOKOGAWA.

Elements of the Vnet/IP bus status

The Vnet/IP bus status shows the communication status of the stations in all domains connected to the Vnet/IP network as well as the devices (such as Layer 3 switches) connecting domains.

The Vnet/IP bus status consists of the following three elements:

- Bus status in own domain
- Communication status of devices connected between domains
- Bus statuses of other domains

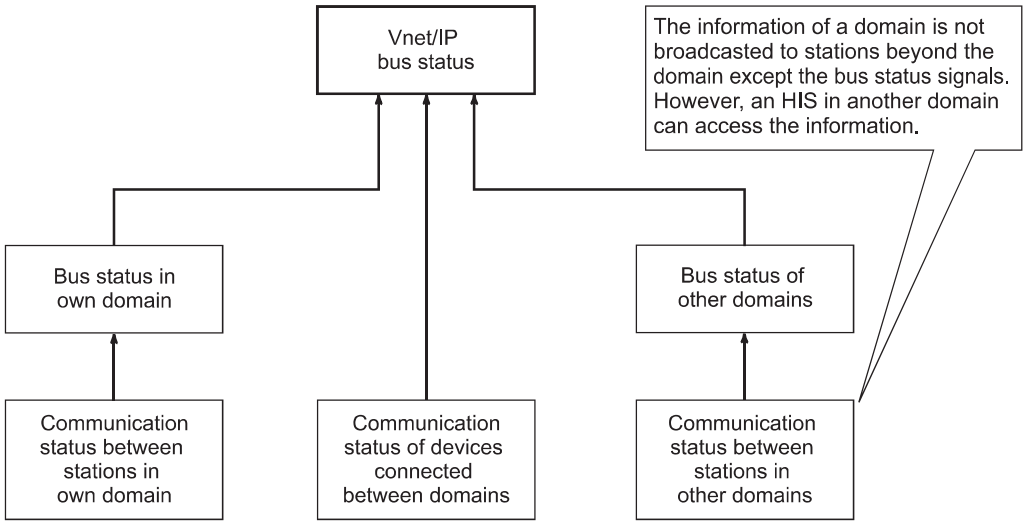

Figure H7-1 Elements of the Vnet/IP bus status

Displaying the station communication status of a domain

Each station in a Vnet/IP domain diagnoses bus statuses mutually using bus 1 and bus 2.

Communication statuses for a station are shown as follows. A station with duplex CPU modules has four types of communication status. The “control side station” mentioned here includes non-redundant stations such as SENG, HIS, and SCS with single CPU configuration.

- Control side communication status between stations
- Communication status when the control side station communicates with the standby side station
- Communication status when the standby side station communicates with the control side station
- Standby side communication status between the stations

Based on this diagnostic information the communication statuses of all stations in a domain can be displayed on the HIS Network Status Display dialog box.

Bus status in a domain

The bus status in a domain is created from the communication status among stations in each domain. If the bus status shows abnormality, the meaning varies with the type of failure:

- Either bus failure (either bus 1 or bus 2)
  When either bus 1 or bus 2 encounters communication error, the status of the bus will be indicated as abnormal.
- Both bus failure (both bus 1 and bus 2)
  If both buses encounter errors, the first one will be indicated as abnormal. Failure of both buses cannot be indicated.

TIP

If both buses are failed to communicate with a specific station, it will be indicated as the station failure, and the bus status will not be indicated as abnormal.

Communication statuses of devices connecting domains

The Vnet/IP domains communicate with each other using bus 1 and bus 2 and the communication status can be monitored. On the HIS Network Status Display dialog box, the communication statuses of devices on different domains can be displayed.

The bus status of one domain is broadcasted to all stations in all domains through the communication between domains.

Priority of the Vnet/IP bus status

The Vnet/IP bus status represents a summary of all communication statuses in the following order:

- Bus Status in Own Domain
  If the bus status of own domain is abnormal, it is reflected in the Vnet/IP bus status. In case of either bus failure, the status of the failed bus is handled as abnormal. In case of both bus failures, only the status of the bus in which abnormality is detected first is handled as abnormal.
- Communication Statuses of Devices Connecting Domains
  While the bus status of own domain is normal, the communication statuses of devices connecting domains are reflected in the Vnet/IP bus status. In case of either bus failure, the status of the failed bus is handled as abnormal. In case of both bus failures, only the status of the bus in which abnormality is detected first is handled as abnormal.
- Bus Statuses of Other Domains
  If the communication statuses of all devices connecting domains are normal, the bus statuses of other domains are reflected in the Vnet/IP bus status. However, even if a different bus is abnormal in different domains, the Vnet/IP bus statuses of both buses are not handled as abnormal, and only the status of the bus in which abnormality is detected first is handled as abnormal.

I. Maintenance

This section describes the procedures and precautions when maintaining ProSafe-RS devices and field devices, and how to set the system time. It also describes the tools that you can use during maintenance.

I1. Maintenance of devices

You must follow the procedures, precautions and all other information specified in this section with care and consideration when maintaining the ProSafe-RS equipment, software or field devices.

Before starting the maintenance work of devices, you need to take prior measures to avoid impact on the field devices due to maintenance. You can use the forcing function and override function for the prior measures and maintenance.

I1.1 Utilizing the forcing and override functions during maintenance

For the purpose of SCS maintenance, it may be necessary to fix or forcibly change the input/output values or values used in application logics. In such cases, the forcing and override functions can be used.

Forcing allows fixing channel input/output values of I/O modules (locking values) from the SCS Manager of SENG and forcibly changing the values (setting values). The following items are the targets of forcing.

- Input/output channels of AIO/DIO modules
- Subsystem communication data
- Safety subsystem communication data
- Variable included in application logic
- Inter-SCS safety communication data
- SCS link transmission data

In addition, it is possible to monitor the lock status in the application logics and forcibly cancel the lock status by using system function blocks (SYS_FORCE, SYS_FORCE_LT, SYS_FORCE_BD, SYS_FORCE_SC, SYS_FORCE_SF).

In the case of integration with CENTUM, variable values can be set by overriding them from HIS.

The following table shows the difference between forcing and override.

Table I1.1-1 Difference between forcing and override

Items where there is a difference between the two functions	Forcing	Override
Purpose	Maintenance of SCS and debugging of applications that are done through SENG	Maintenance of SCS through HIS in the CENTUM Integration Structure
SCS Security Level	The security level has to be set to 1 or 0.	An override is executable when the security level is 2.
Necessity of Programming	Programming is not necessary.	Application logic needs to be programmed with override function blocks.
Designation of output values	Output values can be specified in the I/O Lock Window, etc.	When an override is activated during execution of application, the preprogrammed value is output as an overridden value.
Conditions for locking a variable	Whether or not forcing can be performed depends on the SCS security level.	A program can be written that enables and disables override by using a mechanical key switch or other means.

I1.1.1 Override

In the CENTUM Integration structure, I/O values can be set to a specified value that is different from the actual I/O value by operation from HIS while the system is controlled normally by SCS. This operation is called override.

Override can be executed at an SCS security level of 2.

Executing override requires to create application logic with the override FB.

- There are two types of override FBs. One type is grouping override FB which can handle override actions in a group. The other is override FB which does not handle override in a group.
- If the total number of override FBs and grouping override FBs in the ready state for overriding exceeds the limit specified by the SYS_OVR function block, a diagnostic information message is issued to inform user of it.
- If the total number of overridden override FBs and grouping override FBs exceeds the limit specified beforehand by the SYS_OVR function block, a diagnostic information message is issued to inform user of it.
- If the duration in the ready state for overriding exceeds the limit specified beforehand by the SYS_OVR function block, a diagnostic information message is issued to inform user of it.
- If the duration of override exceeds the limit specified beforehand by the SYS_OVR function block, a diagnostic information message is issued to inform user of it.
- Using the SYS_OVR FB can forcefully cancel override for all variables.

SEE ALSO For more information about details on managing the override FBs, refer to:

B4.5, “Status management of function blocks used for override” in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

I1.1.2 Utilization of the forcing function in SCS maintenance

The forcing function can be used for the following purposes, after all wiring is completed but before the start of actual operation, as well as during maintenance after starting the actual operation.

- Disconnection of Input/Output Modules
- Maintenance of Input/Output Channels
- Prevention of nuisance tripping caused by inter-SCS safety communication during online change downloading or offline downloading

SEE ALSO For more information about prevention of nuisance tripping caused by inter-SCS safety communication during online change downloading or offline downloading, refer to:

"■ Locking Inter-SCS safety communication and SCS link transmission data at online change" on page E1-27

■ Precautions for forcing functions

IMPORTANT

If you lock any internal variable in SCSP3/SCSL2/SCSP2, the application runtime becomes longer, that is, the CPU load increases. You should lock internal variables for engineering and maintenance purposes only.

- When physical data of an output channel are changed by forcing, consider possible effects on the field before performing forcing.
- During forcing, you should avoid conflict with the override operation from HIS.
  Check the output values of the SYS_OVR function block to see whether any overridden instances and instances in a status where they can be overridden exist.

  Check the diagnostic information messages indicating that the switch input of an override FB was turned ON and the diagnostic information messages showing that values were overridden, and make sure not to affect the same loop unintentionally.
- When displaying variable names in a system alarm, no more than 80 single-byte characters can be displayed. Choose variable names that do not exceed this maximum length, so that variables can be identified when locking/unlocking forcing and overriding.

SEE ALSO For more information about CPU load when internal variables are locked, refer to:

A7.3, "Locking of internal variables and performance in SCSP3/SCSL2/SCSP2" on page A7-10

■ Example of procedure for setting data with forcing

1. Set the security level of SCS to 1.
   Check that the security level of SCS is set to 1 with the Diagnostic Information Message
2. Lock I/O variables or internal variables.
   Check that the names of the locked variables are correct with the Diagnostic Information Message.
3. Set a value to the I/O variables or internal variables.
   Check that the variable names and the data set are correct with the Diagnostic Information Message.

4. Check applications with the set data.
5. Set the I/O variables and the internal variables so as not to cause any effects on the applications when another value to the variables are unlocked.
   - Check that the variable names and the data set are correct with the Diagnostic Information Message.
   - Check that the logical data of I/O variables are the same as the physical data and the data status is GOOD.
6. Unlock the I/O variables or the internal variables.
   Check that the unlocked variable names are correct with the Diagnostic Information Message.
7. Set the security level of SCS back to 2.
   Check that the security level of SCS is set to 2 with the Diagnostic Information Message

Locking for online change download

If online change of an I/O module and application logic is required while SCS is in operation, you must investigate whether there is a need to lock the I/O module to prevent a false trip, and lock the I/O module if necessary.

The following figure shows the procedure to lock the I/O module prior to online change download.

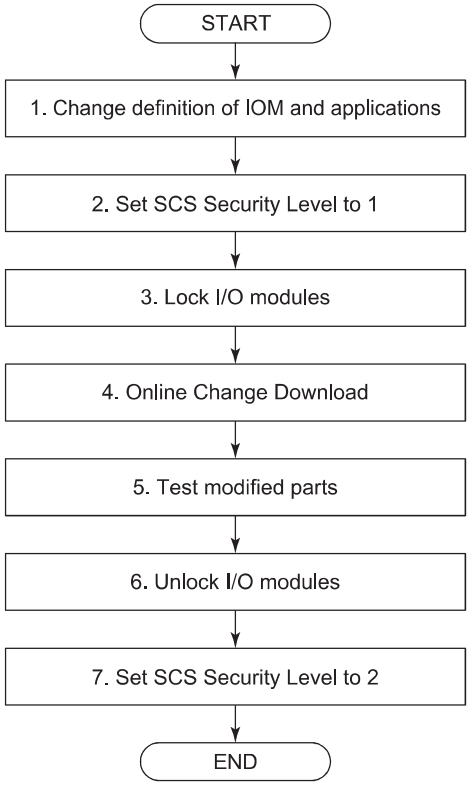

Figure I1.1.2-1 Procedure to lock I/O module prior to online change download

1. The engineer modifies the application and uses the Integrity Analyzer and Cross Reference Analyzer to analyze the modified application. If the application logic has also been modified, use the logic simulation test to check the modifications.
2. Change the SCS security level to Level 1 by using the SCS Security Level Operation Dialog.
3. Locking all I/O modules related to online change with the I/O Lock Window is recommended.

4. Perform an online change download.
5. Start the Debug mode for checking the modified parts.
6. Unlock all locked I/O modules with the I/O Lock Window. At this time, check with great care whether the output values are changed or not. Finish the Debug mode after unlocking the I/O modules.
7. Return the SCS security level to Level 2 by using the SCS Security Level Operation Dialog.

CAUTION

If you change some settings of an output module and perform an online change download to an SCS in R2.01 or earlier system program release number, you need to prevent the system from an unexpected shutdown when the value of the output module becomes 0. Preventive measure should be taken on the field device side in advance.

Maintenance of input/output channels

When performing maintenance of input/output channels, the forcing function is used to fix the values of the corresponding channels so as to prevent adverse effect on the operation of other applications.

Prevention of nuisance tripping when replacing a faulty module

If a channel of the input module fails in single configuration, the replacement of input module is required. The forcing function is used to fix input values of all channels to the current values to prevent nuisance tripping.

Similarly, if a channel of the output module fails in single configuration, the replacement of output module is required. The forcing function is used to fix the data status of all channels of the output module to the current values to prevent nuisance tripping in other output modules that refer to this channel.

Prevention of nuisance tripping due to online change download

When downloading online changes to the application logic or input/output modules, the forcing function is used to fix output values of all channels that may be influenced by this change, in order to prevent nuisance tripping.

In downloading online changes to an input/output module online, the forcing function is used to fix the input/output values of all channels of the corresponding input/output module to the current values in order to prevent nuisance tripping.

CAUTION

- For the output modules targeted for online change download, field bypasses are required so as to prevent plant shutdown.
- In online change download of output modules, if the channel status of the module is used as a reference by another output module, the channel of another output module may mistakenly generate a trip signal. To prevent this, the output modules linked to the online-changed module should be locked during online maintenance.

Prevention of nuisance tripping due to Inter-SCS safety communication errors at download

Nuisance tripping due to inter-SCS safety communication errors can be prevented by locking inter-SCS safety communication when performing online change download and offline download.

CAUTION

Be sure to check that LD (Logical Data) and PD (Physical Data) match when unlocking after the completion of download operation.

Unlocking in the status where LD and PD do not match may cause nuisance tripping.

At online change download

In the case of online change download, launch the Inter-SCS Communication Lock Window from an SCS project in which online change download is to be performed, and then lock stations on the producing and consuming sides. Nuisance tripping caused by online changes can be prevented.

Using Inter-SCS safety communication data lock function at offline download

When executing offline download of the producer SCS of inter-SCS safety communication, it is possible to prevent false trips caused by the offline download by locking inter-SCS safety communication at the consumer stations of the inter-SCS safety communication.
An overview of the locking and the procedure for executing offline download is described as follows.

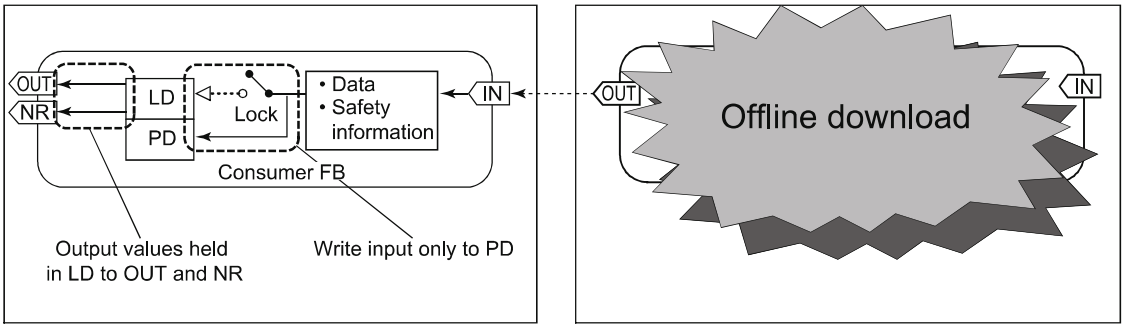

Figure I1.1.2-2 Example of locking Inter-SCS safety communication at offline download

1. Set the security level of SCS that receives inter-SCS safety communication data from the SCS that executes offline download to 1.
   Check that the security level of SCS is set to 1 with the diagnostic information messages.
2. Lock the consumer FB of the station where offline download is performed using the Inter-SCS Communication Lock window of the SCS that receives inter-SCS safety communication data.
   Check that inter-SCS safety communication has been locked with diagnostic information messages.
3. Set the security level of SCS that executes offline download to 0.
   Check that the security level of SCS is set to 0 with the diagnostic information messages.
4. Execute offline download.

5. Perform the output enable operation on the SCS that executed offline download.
   Check the output enabled status with diagnostic information messages.
6. Check that the logical data and physical data match and that the data status is GOOD in the Inter-SCS Communication Lock window of the SCS that receives inter-SCS safety communication data.
7. Unlock the consumer FB in the Inter-SCS Communication Lock window.
   Check that the inter-SCS safety communication is unlocked with diagnostic information messages.
8. Set the security level of the SCS that receives inter-SCS safety communication data to 2.
   Check that the security level of SCS is set to 2 with the diagnostic information messages.

I1.2 Maintenance for ProSafe-RS equipment

With SCS, procedures for maintenance vary depending on faults such as when dual-redundant CPU module or I/O module is replaced because of a fault or when a module in a single configuration fails. Take care for the maintenance procedure not to cause a nuisance tripping when maintenance is performed during running the plant.

Actions to be taken upon device errors

When you detect hardware errors by system alarms on HIS or alarm devices such as alarm lamps that indicate generation of diagnostic information messages, follow these steps:

1. Use the SCS Maintenance Support Tool of the SENG to identify the failed location and the cause for the error.
2. Repair the failed location.
   When a CPU module or I/O module of an SCS stops, you may be required to replace the module. Replace the module by following the procedure and precautions specified in the user's manual.
3. Confirm that all hardware devices are working properly either from the SCS State Management window or by ensuring that the alarm devices have been reset.

Precautions for ProSafe-RS device maintenance

During the maintenance of ProSafe-RS devices, you must be careful because the devices behave as follows:

- It takes about 8 seconds for an I/O module to get back to the normal state when it recovers from a failure such as when applying the power to I/O modules.
- When executing the APC operation for dual-redundant SCS, a COPY message is issued twice.
- When one power supply module of the "CPU node" fails, not only the CPU node but also I/O node 1 generates a signal that indicates failure of one power supply module. As a result, two diagnostic information messages are issued.

Workflow of CPU module maintenance

This section describes the workflow of CPU module maintenance. Before replacing the CPU module, read a whole description to understand the workflow of the maintenance and the precautions.

The procedure to be taken when the CPU module fails varies depending on whether the CPU module is of single configuration or dual-redundant configuration.

In addition, for the stand-alone ProSafe-RS system, you may need to clear the CPU module setting information before replacing the CPU module. For the CENTUM integration system, you may need to download the information of Domain Properties after replacing the CPU module. For detailed procedure, refer to the link included in each description.

Workflow of CPU module failure (Single configuration)

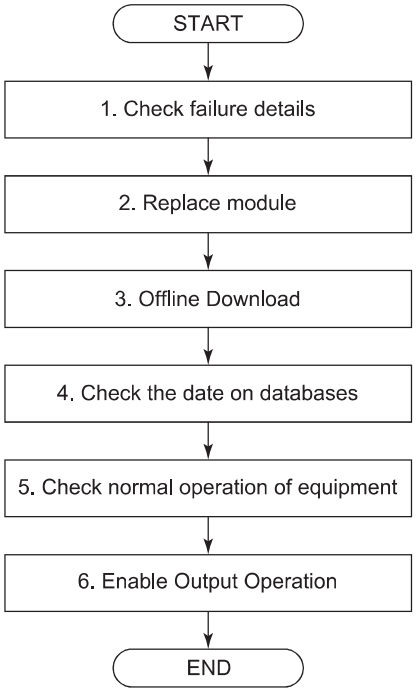

Figure I1.2-1 CPU module failure (Single configuration)

1. The engineer starts the SCS State Management window from SENG of the SCS where a fault occurs and confirms the diagnostic information message. Confirm the measures against the fault with the Help Dialog of Diagnostic Information Message and determine whether to replace the CPU module.
2. If the module needs to be replaced as a result of the step 1, the maintenance personnel removes the failed CPU module from the node and installs a new CPU module. Follow the instruction in the link included at the end of this section when you replace the CPU module.
3. The engineer executes master database offline download from SENG. (If downloading to the CPU module has been executed even once, the last application remains in the flash memory of the CPU module. Be sure to execute master database offline download after replacing the CPU module.)
4. The CPU module starts after the download is completed.
   The engineer displays date of each database for POU DB, Variable DB, System DB and Integration DB on the Database Validity Check Tool, when the SCS is in waiting mode, to confirm that latest version is loaded.
5. The maintenance personnel confirm that the CPU module has started normally from the SCS State Management window in SENG or from LED of the CPU module. Furthermore, the engineer confirms that all SCS equipment are in normal state with the SCS State Management window.
6. The maintenance personnel perform the enable output operation from the SCS State Management window.

SEE ALSO

For more information about details of Output enable operation, refer to:

C8., “Output enable operation” on page C8-1

For more information about procedure required before and after replacing CPU module, refer to:

I6., “Procedures and precautions for adding or replacing Vnet/IP devices” on page I6-1

Workflow of CPU module failure (Dual-redundant configuration)

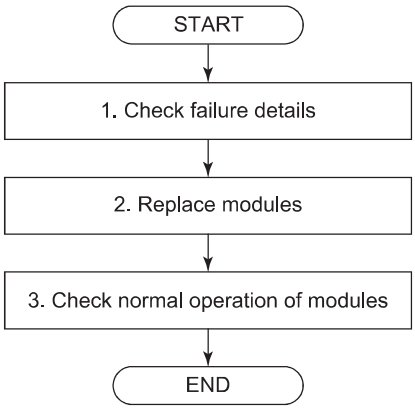

Figure I1.2-2 CPU module failure (Dual-redundant configuration)

1. The engineer starts the SCS State Management window from SENG of the SCS where a fault occurs and confirms the diagnostic information message. Confirm the measures against the fault with the Help Dialog of Diagnostic Information Message and determine whether to replace the CPU module.
2. If the module needs to be replaced as a result of the step 1, the maintenance personnel removes the failed CPU module (on standby) from the node and installs a new CPU module. Follow the instruction in the link included at the end of this section when you replace the CPU module.
3. When the new CPU module is installed, programs and databases of the CPU module on control are automatically copied to the new CPU module. The maintenance personnel confirms with LED of the module or the SCS State Management window in SENG that the module has started normally.

IMPORTANT

Do not pull out the CPU module online and turn off the power while the module is writing to the flash memory. Whether the CPU module is writing can be confirmed by using LED of the CPU module.

SEE ALSO For more information about procedure required before and after replacing CPU module, refer to:

I6., “Procedures and precautions for adding or replacing Vnet/IP devices” on page I6-1

Password setting in replacing CPU

- If CPU is in dual-redundant configuration and you must replace the standby side, there is no need to re-set passwords for the work. After the Standby side is replaced, the passwords for changing Security level stored in the control side are automatically copied to the standby side.
- In a single CPU configuration, if the CPU is replaced and programs remain in the memory on the new CPU module, the CPU starts. Its Operating mode is Waiting, so output value of application logic is not output to the field.
  In this status, press Reset switch, stop the CPU, and offline download the master database. After completion of the download and the CPU is started, set the passwords. The passwords in the memory on the CPU module is initialized, so there is no need to enter the previous passwords.

- In a single CPU configuration, if the CPU is replaced and no program remains in the CPU memory on the new CPU module, the CPU is in a halt status. In that status, offline downloads the master database. After completion of the download and the CPU is started, set the passwords. There is no need to enter the previous passwords.

Maintenance of I/O modules

If the I/O module generates an error, you must use the IOM Report to investigate the cause before commencing troubleshooting. Maintenance procedures vary depending on the error code reported in the IOM Report.

SEE ALSO For more information about details on IOM Report, refer to:

H3., “Checking diagnostic information by using IOM Report” on page H3-1

Overview of I/O module maintenance procedure and precautions

The precautions and maintenance procedure when an I/O module has stopped are described as follows:

IMPORTANT

Observe the following precautions when one of the redundant pair of I/O modules has failed and you must fix it:

- If you pull out the failed I/O module, do not insert it again.
- When you replace the I/O module, do not insert an I/O module that is not assured as normal.

If you do not observe these precautions, the field side may be adversely affected if the inserted module is faulty.

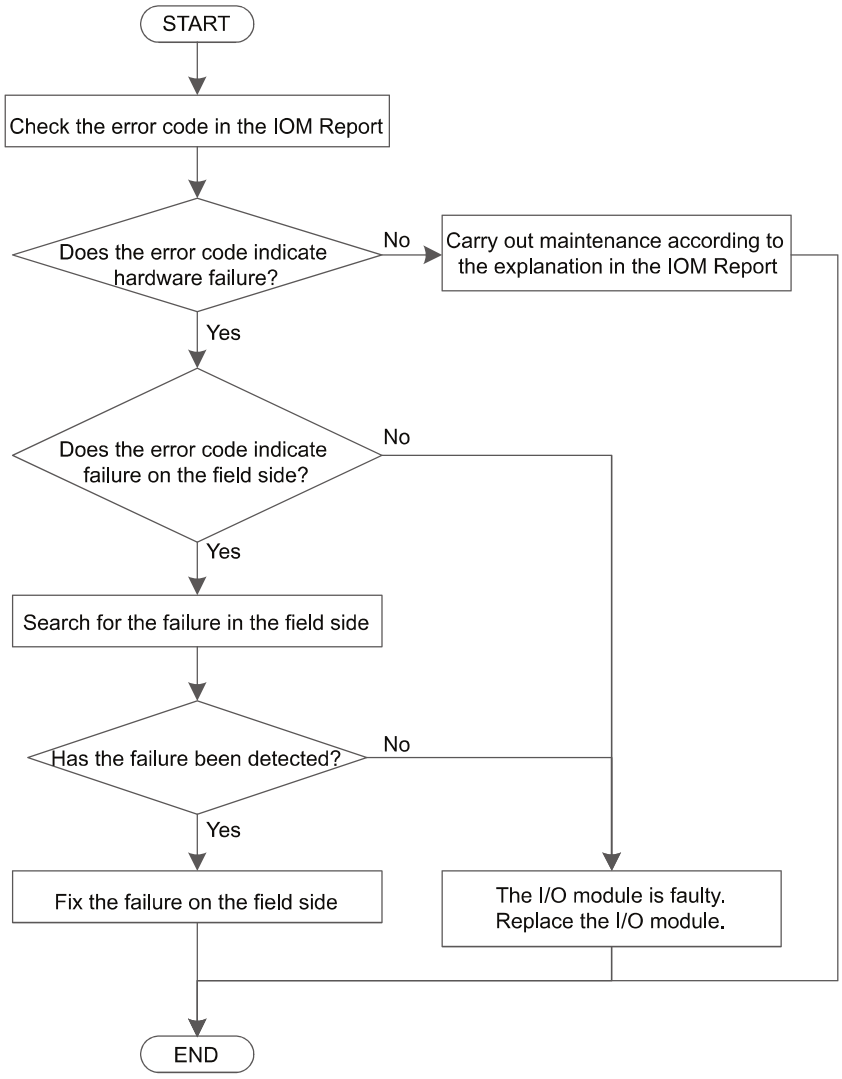

Figure I1.2-3 I/O module maintenance procedures

SEE ALSO For more information about procedures for replacing the I/O Module, refer to:

"● Procedure for when the I/O module is faulty" on page I1-15

● Hardware failure error codes possibly caused by failures on the field side

The cause of the I/O module stopping can be checked in the IOM Report.

Even when the IOM Report shows an error code for hardware failure, the module may have actually stopped due to a failure on the field side, not a hardware error. If the IOM Report shows any of the following error codes, follow the troubleshooting procedure that applies when there is a possibility of a failure on the field side.

Table I1.2-1 IOM Report error codes possibly caused by failures on the field side

Code (hexadecimal)	Display	Description
0101 5502 0401 5502 (*1)	Output Readback Error	An error has been detected in the readback process for the output value. Check the field wiring of the analog output module for any abnormality such as inter-channel short circuit, and also confirm that the total resistance of all connected cables and devices does not exceed the allowable output load resistance of the output module, which is specified in the General Specifications (GS).
0101 5504 0401 5504	Output Channel Stuck at ON	A failure that the output channel is unable to change from ON to OFF has been detected. Check if there are any field wiring errors such as inter-channel short circuit.
0107 5507 0407 5507 (*1)	IOM Channel Fail	There have been some errors with the channel area of the input/output module. Check if there is any input of a signal value at a level between ON and OFF or chattering.

*1: For a channel failure, the error code and the error status will vary depending on whether the I/O module is of a duplex configuration or a single configuration.
- The upper error code is for a redundantly configured I/O module, while the lower error code is for a non-redundantly configured I/O module.
- If the input/output module is in a redundant configuration, this error will be an IOM Fail error. In a non-redundant configuration, the error will occur only to the failed channel.

Troubleshooting procedure when error is possibly caused by failures on the field side

If the IOM Report shows an error code that may be caused by a failure on the field side, follow these steps to restore the I/O module:

1. Search for wiring error or failure on the field side.
2. Repair the wiring error or failure on the field side to remove the cause of error corresponding to the error code.

TIP

If the cause of error is not on the field side, it is a hardware failure of the I/O module. Follow the procedure for when the I/O module is faulty.

3. Reset the I/O module that has stopped. Perform one of the following actions based on the system program release number of the SCS:
   - SCS system program release number is R3.02.00 or later

     Select the stopped I/O module and run IOM download manually. IOM reset is performed at the same time.

TIP

IOM is reset only if the AIO/DIO modules are in single configuration or they are the standby side of duplex configuration and if their HRDY lamp is off.

   - SCS system program release number is earlier than R3.02.00
     Pull out and insert the I/O module again. IOM reset is performed.
4. Check that the I/O module has recovered to normal in the SCS State Management window.
5. After an output module has recovered to normal, perform the output enable operation in the SCS State Management window.

SEE ALSO

For more information about IOM Download operations, refer to:

I4.6, “IOM Download tool” on page I4-80

Procedure for when the I/O module is faulty

Follow these steps when you have determined that there is an I/O module hardware failure:

1. Replace the faulty I/O module with one that operates normally.
2. After replacing the module, perform IOM download.
   However, when replacing the standby side of the redundant AIO/DIO modules, you do not need to execute the IOM download manually if the automatic IOM download is enabled in the SCS.

TIP

To enable automatic IOM download, you must set "Automatic IOM Download" to Enable in the SCS Constants Builder. Once it's set, the SCS automatically downloads configuration information from the control side module to the standby side module after the module is replaced.

3. Confirm that the replaced module is working properly either from the SCS State Management window or by ensuring that the alarm device has been reset.

SEE ALSO

For more information about how to replace the I/O module of the FIO node, refer to:

E4.7, “Replacing FIO I/O modules” in Hardware User's Guide (IM 32P06C10-01EN)

For more information about how to replace the I/O module of the N-IO node, refer to:

E5.3, “Replacing N-IO I/O modules” in Hardware User's Guide (IM 32P06C10-01EN)

Replacing a fire and gas communication module

Follow these steps when you have determined that there is a fire and gas communication module failure:

1. In the Communication I/O Lock Window, lock the fire and gas communication module.
2. Remove the failed fire and gas communication module form the node.
3. Insert a new fire and gas communication module in the node.
4. Perform IOM download.
5. In the Communication I/O Lock Window, check that the physical data status of the input data is GOOD.
6. Release the lock of the fire and gas communication module.

Procedures for changing the single/redundant specification of AIO/DIO modules installed on the FIO node

Follow these steps to offline change the single/redundant specification of AIO/DIO modules installed on the FIO node:

1. Disconnect the I/O cables (or terminal blocks) of the modules.
2. If you change two adjacent existing single modules to dual-redundant configuration, pull out one of the modules and insert it again.
3. Perform either of the following operations:
   Operations differ, depending on the engineering method.
   - If you are performing RS original engineering, change the definition by using I/O Wiring View and perform offline download.
   - If you are performing I/O list engineering, change the definition by using the IOM Definition Editor and perform offline download.
4. Connect the I/O cables (or terminal blocks).

Maintenance specific to N-IO nodes

You can perform the following maintenance tasks for N-IO nodes through the NIU maintenance port.

Periodic maintenance

Follow these steps to stop the SCU for the periodic maintenance of the plant and perform maintenance of N-IO nodes:

IMPORTANT

Set the security level to 1 or below before stopping the SCU, and then enable the maintenance port.

1. Enable the maintenance port of NIU in the target NIU nodes for maintenance.
2. Perform maintenance work of N-IO nodes, which have an NIU with an enabled maintenance port, by using the FieldMate Validator.
3. Disable the maintenance port of the target NIU after the completion of the maintenance work, and prohibit access from the maintenance port.
4. Verify that the maintenance ports of all NIU are disabled on SENG or HIS.

Adding N-IO nodes

Follow these steps to add N-IO nodes to the existing SCU:

1. Configure the node numbers of the N-ESB bus and optical ESB bus in all NIUs that have been supplied.
2. Use the FieldMate Validator to perform the loop checking, to check the functionalities and to configure the field device and N-IO I/O module under the N-IO node.
3. Connect to the existing SCU.
4. Disable the maintenance port of the extended NIU to prohibit access from the maintenance port.
5. Verify that the maintenance ports of all NIU are disabled on SENG or HIS.

Replacing a faulty N-ESB bus module

When one of the redundant N-ESB bus modules installed on NIU has failed, follow these steps to replace the faulty module:

1. Remove the faulty N-ESB bus module from NIU.
2. Insert the replacement N-ESB bus module to NIU.
3. Disable the maintenance port of the replacement N-ESB bus module to prohibit access from the maintenance port.
   Note that the maintenance port of NIU is automatically disabled if the security level is 2. However, if the maintenance port is in the maintenance status, the maintenance port retains the maintenance status and does not go into the disabled state even when the security level is set to 2.
4. Verify that the maintenance ports of all NIU are disabled on SENG or HIS.

Behaviors during N-IO node maintenance mode and recovery procedure

This section describes the system behaviors when an N-IO node is placed in maintenance mode and the procedure when the node recovers from the maintenance mode.

Operations during the maintenance mode

When an N-IO node is placed in maintenance mode, the system operates as follows:

- CPU processing
  The CPU sets the "input value at error occurrence," which is the value pre-defined in an I/O parameter by the user, for all input channels of the I/O modules that were installed in the N-IO node (which is in maintenance mode), and changes the data status to "BAD".

  The CPU sets the fail-safe value, which is the value pre-defined in an I/O parameter by the user, on the physical data for all output channels of the I/O modules that were installed in the N-IO node (which is in maintenance mode), and places the output channels in output disable status. It also changes the data status to "BAD".

  The CPU stops the data update to the I/O module that was installed in the N-IO node (which is in maintenance mode).

- Error notification
  It sends a message when the safety control station status is changed to the maintenance mode. It also sends a message on recovery that the maintenance mode of the safety control station status is canceled.

Recovery procedures

1. Switch the N-IO node from the maintenance mode to the online mode.
   Data status returns to GOOD and a maintenance mode cancellation message is sent.

   Execute following operation if the output module is installed in the N-IO node.

2. From the SCS Maintenance Support Tool of the SENG, run the output enable operation.
   Output values from the application logic are output.

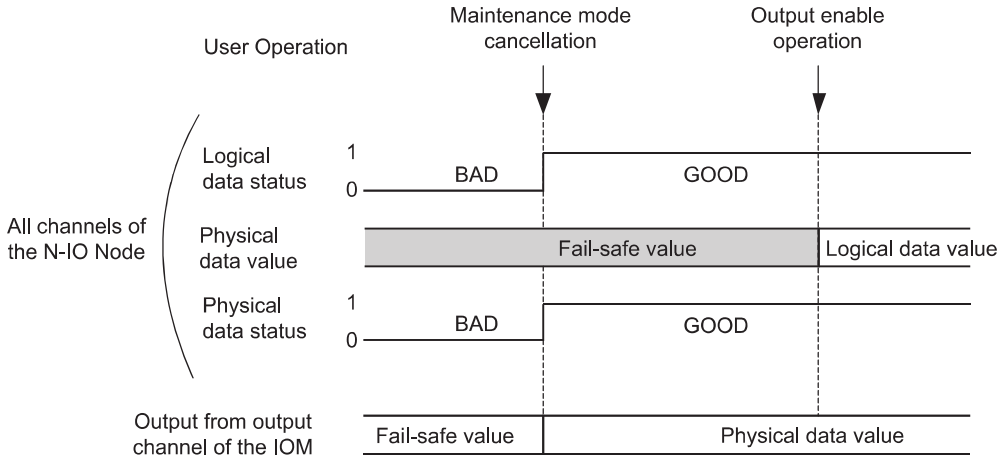

Figure I1.2-4 Operations during maintenance mode cancellation

TIP

Effective range of recovery operations are limited to I/O modules of N-IO nodes that are connected to NIU in maintenance mode. Other NIUs that are connected to the target NIU in a daisy chain are not affected.

I1.3 Maintenance of field devices

For maintenance of field devices, it is necessary to take measures on the ProSafe-RS side so as not to cause a nuisance tripping due to field signals changed by maintenance.
The procedure for maintenance of filed devices is as follows.

1. Take required bypass to avoid generating a nuisance tripping due to maintenance.
2. Perform maintenance of field devices.
3. Test field devices.
4. Remove the bypass taken in step 1.

In ProSafe-RS, I/O values related to maintenance are locked with either of the following ways to avoid a nuisance tripping during maintenance.

- Forcing from SENG
- Override from HIS in CENTUM Integration Structure

I1.4 Maintenance of field wireless system devices

The section describes the procedures for maintenance of field wireless system devices.

IMPORTANT

When you download settings to YFGW410 by using FWMC, the YFGW410, wireless field devices on the field wireless subnet, or GS01 may restart, depending on the changes made to the YFGW410 settings. Therefore, use FWMC to find the devices that will restart and lock the relevant communication data before you download settings to YFGW410 from FWMC.

A field wireless subnet refers to a field wireless network that consists of YFGW510 and its subordinate wireless field devices.

The devices that restart and the data to be locked are as follows:

- When YFGW410 will restart
  All communication data that is obtained through the YFGW410 that will restart
- When wireless field devices on the field wireless subnet will restart
  All communication data that travels through the wireless field devices that will restart
- When GS01 will restart
  All communication data of the GS01 that will restart

SEE ALSO

For more information about how to configure YFGW410 and functions of the field wireless management console (FWMC), refer to:

YFGW410 Field Wireless Management Station (IM 01W02D01-01EN)

For more information about tasks related to field wireless system devices, refer to:

YFGW410 Field Wireless Management Station Read Me First (IM 01W02D01-11EN)

I1.4.1 Changing the setting information of YFGW410

You must change the setting information of YFGW410 when you change the name of the PROFINET network name, the update cycle or Watch Dog Timer for PROFINET communication, or the PROFINET modules to assign to the YFGW410.

To change the setting information of YFGW410, you must download configuration data to YFGW410 by using FWMC.

When to download should be decided through discussion with the engineer of the field wireless system.

Follow these steps to change the setting information of YFGW410.

1. Reflect the information of the YFGW410 onto the safety communication I/O list, PROFINET definitions, communication definitions, and applications, etc.
2. In the Communication I/O Lock Window, lock the S2LP131 connected to the YFGW410.
3. Perform an online change download with SCS Manager.
4. In the Communication I/O Lock Window, check that the physical data status of the input data is GOOD.
5. Release the lock of the S2LP131 connected to the YFGW410.

I1.4.2 Replacing YFGW410

To replace YFGW410 when one of a redundant pair of YFGW410 has failed, you do not need to provide any curing measure on the ProSafe-RS system side.

When both of a redundant pair of YFGW410 have failed, you can replace the YFGW410 by using the same procedure that you follow to replace a non-redundant YFGW410.

Follow these steps to replace a non-redundant YFGW410:

1. In the Communication I/O Lock Window, lock all of the communication definitions applicable to the YFGW410 being replaced.
2. Remove the failed YFGW410.
3. Attach the new YFGW410.
4. In the Communication I/O Lock Window, check that the physical data status of the input data is GOOD.
5. Release the lock of all of the communication definitions applicable to the YFGW410 that was replaced.

I1.4.3 Replacing YFGW510

To replace YFGW510 when one YFGW510 in a DuoCast configuration has failed, you do not need to provide any curing measure on the ProSafe-RS system side.

When both YFGW510 in a DuoCast configuration have failed, you can replace the YFGW510 by using the same procedure that you follow to replace a non-DuoCast YFGW510.

Follow these steps to replace a non-DuoCast YFGW510:

1. In the Communication I/O Lock Window, lock the communications for all communication definitions relevant to the YFGW510 to be replaced.
2. Remove the failed YFGW510.
3. Install a new YFGW510.
4. In the Communication I/O Lock Window, check that the physical data status of the input data is GOOD.
5. Release the lock of the communications for all communication definitions relevant to the YFGW510 that was replaced.

I1.4.4 Removing YFGW510

When you remove YFGW510, you must download configuration data to the relevant YFGW410 by using FWMC.

When to download should be decided through discussion with the engineer of the field wireless system.

When you make a maintenance plan, consider that it will take a maximum of two minutes after S2LP131 is stopped until it restarts in order to update PROFINET definitions.

Follow these steps to remove a YFGW510:

1. Delete YFGW510 from the safety communication I/O list, PROFINET definitions, communication definitions, and other lists and definitions, and application logic.
2. In the Communication I/O Lock Window, lock the S2LP131 connected to the YFGW510 being removed.

TIP

The reason for locking S2LP131 is because S2LP131 will be restarted to delete the relevant communication definitions. The communication definitions must be deleted for the following reasons:

- It is assumed that GS01 is also removed when YFGW510 is removed. If GS01 is removed, communication definitions for gas concentration or other data must be deleted.
- Even if GS01 is not removed, deletion of communication definitions is required if the system is obtaining BBR_STATUS of YFGW510.

3. Remove the YFGW510.
4. Using SCS Manager, execute an online change download.
5. In the Communication I/O Lock Window, check that the physical data status of the input data is GOOD.
6. Release the lock of the S2LP131.

SEE ALSO

For more information about how to change PROFINET definitions, refer to:

E1.5.2, “Applying settings by using PROFINET Configurator” in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

I1.4.5 Adding YFGW510

When you add YFGW510, you must download configuration data to the relevant YFGW410 by using FWMC.

When to download should be decided through discussion with the engineer of the field wireless system.

When you make a maintenance plan, consider that it will take a maximum of two minutes after S2LP131 is stopped until it restarts in order to update PROFINET definitions.

Follow these steps to add a YFGW510.

1. Reflect the information of the YFGW510 being added onto the safety communication I/O list, PROFINET definitions, communication definitions, and application logic.
2. Before you execute an online change download to the SCS, in the Communication I/O Lock Window, lock the S2LP131 that is connected to the YFGW510 being added.
3. Using SCS Manager, execute an online change download.
4. In the Communication I/O Lock Window, confirm that the physical data status of the input data is normal.
5. Release the lock of the S2LP131.

SEE ALSO For more information about how to change PROFINET definitions, refer to:

E1.5.2, “Applying settings by using PROFINET Configurator” in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

I1.4.6 Changing the setting information (F-Parameter, communication period) of GS01

The setting information of GS01 includes F-Parameter, which needs to be downloaded to S2LP131, and the communication period, which needs to be downloaded to YFGW410.

TIP When you change only F-Parameters, downloading of configuration data to YFGW410 is not required.

Changing F-Parameter

Follow these steps to change the F-Parameter:

1. Reflect the setting information of GS01 onto the safety communication I/O list, PROFINET definitions, and other lists and definitions.
2. In the Communication I/O Lock Window, lock the S2LP131 connected to the GS01.
3. Using SCS Manager, execute an online change download.
4. When the online change download is complete, check that the physical data status of the input data is GOOD in the Communication I/O Lock Window.
5. Unlock the S2LP131 that you locked in step 2.

Changing the wireless communication period

When you change the wireless communication period, you must download configuration data to the relevant YFGW410 by using FWMC.

When to download should be decided through discussion with the engineer of the field wireless system.

TIP When you change the wireless communication period, you do not need to make any changes in the engineering of ProSafe-RS. Downloading to SCS and S2LP131 is not required, either.

Follow these steps to change the wireless communication period:

1. Before you download the configuration data to YFGW410 by using FWMC, lock the communication data of the GS01 for which you are changing the communication period from the Communication I/O Lock Window.
2. When the downloading of configuration data from FWMC is complete, check that the physical data status of the input data is GOOD in the Communication I/O Lock Window.
3. Unlock the communication data of GS01 that you locked in step 1.

I1.4.7 Replacing GS01

When you replace GS01, you must download configuration data to the relevant YFGW410 by using FWMC.

When to download should be decided through discussion with the engineer of the field wireless system.

Follow these steps to replace GS01 when it has failed:

1. In the Communication I/O Lock Window, lock all of the communication definitions applicable to the GS01 being replaced.
2. Remove the failed GS01.
3. Attach the new GS01.
4. In the Communication I/O Lock Window, check that the physical data status of the input data is GOOD.
5. Release the lock of all of the communication definitions applicable to the GS01 that was replaced.

I1.4.8 Removing GS01

When you replace GS01, you must download configuration data to the relevant YFGW410 by using FWMC.

When to download should be decided through discussion with the engineer of the field wireless system.

Follow these steps to remove a GS01:

1. Delete GS01 from the safety communication I/O list, PROFINET definitions, communication definitions, and other lists and definitions, and application logic.
2. In the Communication I/O Lock Window, lock the S2LP131 connected to the GS01 being removed.
3. Remove the GS01.
4. Perform an online change download with SCS Manager.
5. When the online change download is complete, check that the physical data status of the input data is GOOD in the Communication I/O Lock Window.
6. Release the lock of the S2LP131.

I1.4.9 Adding GS01

Follow these steps to add a GS01. This section explains the procedures for using a user-defined FB to which GASDTR, PSI_I, and PSI_R as shown in the following figure are embedded as an application for monitoring the gas concentration of GS01 and using the same user-defined FB with the GS01 being added as well.

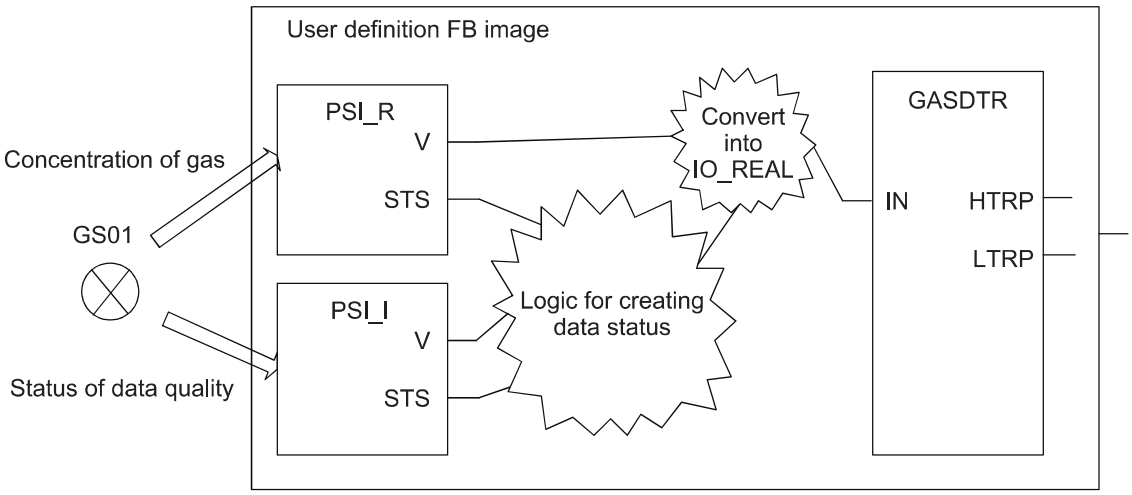

Figure I1.4.9-1 Image of user-defined FB

The flow of tasks is as follows. However, specific operation procedures vary depending on whether or not iDefine is used.

To add GS01, you must configure YFGW410 as well as ProSafe-RS. Therefore, you must download configuration data to the relevant YFGW410 by using FWMC.

When to download should be decided through discussion with the engineer of the field wireless system.

The wok flow for adding GS01 is described below. If you add GS01 without following this work flow, the operation starts from the state where GASDTR has latched a trip signal.

1. Perform an online download onto the SCS for a POU other than the one including the GS01 being added.
2. Perform a forcing of the communication definition being added.
3. Perform an online download onto the SCS for the POU that includes the GS01.

SEE ALSO For more information about how to configure YFGW410, refer to:

- YFGW410 Field Wireless Management Station Read Me First (IM 01W02D01-11EN)
- YFGW410 Field Wireless Management Station (IM 01W02D01-01EN)

When using iDefine

Follow these steps when adding a GS01 by using iDefine. Step 1 is a task to be performed before heading to the site. Step 2 and subsequent steps are tasks performed at the site.

1. Export the SCS project by using AD Organizer.
2. Import the SCS project by using AD Organizer.
   In the SCS Import dialog box, select the [Exclude SCS Project Files] check box and perform the import.
3. Using RS Generation Manager, select the check box for [Skip the reflection of program POUs] and then click [Build].

4. In the Communication I/O Lock Window of SCS Manager, lock the S2LP131 including the GS01 being added.
   Lock all inputs in bulk or lock all communication definitions.
5. Perform an online change download with SCS Manager.
   Release the lock of the existing GS01 at any time after this upon confirming that communication has been restored.
6. In the Communication I/O Lock Window of SCS Manager, run a forcing of the communication data wired to the GS01 being added into a normal value. At this time, check that the gas concentration with the physical data in the Communication I/O Lock Window is within a normal range.
   The values subjected to forcing are as follows:
   - PSI_R.v (gas concentration): A value which does not exceed the High/Low trip levels of GASDTR
   - PSI_R.sts (status of fire and gas communication): TRUE
   - PSI_I.v (data quality status of gas concentration): 128
   - PSI_I.sts (status of fire and gas communication): TRUE
7. Click [Build] in RS Generation Manager.
   A build process runs for the SCS project.
8. Using Project Comparing Tool, check that the following projects match.
   - The original SCS project exported in step 1
   - The SCS project that is to be downloaded at the site
9. Perform an SCS online change download by using SCS Manager.
10. Release the lock for every communication definition for which communication with the added GS01 has been restored.

SEE ALSO

For more information about exporting SCS projects, refer to:

"■ Importing SCS projects" on page E2-5

For more information about how to operate RS Generation Manager, refer to:

D4., "Overview of RS generation" on page D4-1

For more information about how to operate Communication I/O Lock Window, refer to:

F8.11, "Communication I/O Lock window" in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about Project Comparing Tool, refer to:

F6.3, "Comparing two SCS projects" in Engineer's Reference Manual (IM 32P04B10-01EN)

■ When not using iDefine

Follow these steps when adding a GS01 without using iDefine. Procedure 1 is a task to be performed before heading to the site. Procedure 2 and beyond are tasks performed at the site.

1. Perform the following tasks:
   - Export the SCS project by using AD Organizer.
   - Using SCS Manager, export the CSV file of Dictionary, the CSV file of Tag Name Builder, and the PXF file of the entire project.
2. Perform the following tasks:
   - Import the SCS project by using AD Organizer. In the SCS Import dialog box, select the [Exclude SCS Project Files] check box and perform the import.

- Using SCS Manager, import Dictionary.
- Using RS Generation Manager, run the build process.

3. In the Communication I/O Lock Window of SCS Manager, lock the S2LP131 including the GS01 being added.
   Lock all inputs in bulk or lock all communication definitions.
4. Perform an online change download by using SCS Manager.
   Release the lock of the existing GS01 at any time after this upon confirming that communication has been restored.
5. In the Communication I/O Lock Window of SCS Manager, run a forcing of the communication definition wired to the GS01 being added.
   The values subjected to forcing are as follows:
   - PSI_R.v (gas concentration): A value that does not exceed the setting level for the HI and LO trips of GASDTR
   - PSI_R.sts (status of fire and gas communication): TRUE
   - PSI_I.v (data quality status of gas concentration): 128
   - PSI_I.sts (status of fire and gas communication): TRUE
6. Using SCS Manager, import the PXF file of the entire project.
7. Using SCS Manager, import the CSV file of Tag Name Builder.
8. Perform the build by using SCS Manager.
9. Using Project Comparing Tool, check that the following projects match.
   - The original SCS project exported in step 1
   - The SCS project that is to be downloaded at the site
10. Perform an SCS online change download by using SCS Manager.
11. Release the lock for every communication definition for which communication with the added GS01 has been restored.

I2. Maintenance of the system

This section explains proof tests necessary for maintenance of the system and tests for improving the rate of operation.

I2.1 Proof test

Proof tests are periodic tests for verifying that the functions of safety loops consisting of sensors, logic solvers, and final elements are functioning without failure.

This section explains the proof test for logic solvers (ProSafe-RS).

The subject of this proof test is the operation of each channel of input/output modules.

Change the input value or output value of each channel of the modules and check if the modules work as intended.

For dual-redundant configurations, conduct the check on both modules.

I2.2 Tests for improving the rate of operation

For dual-redundant configurations, check that the dual-redundant switchover takes place properly in order to improve the rate of operation. This section explains how to check the dual-redundant switchover of the CPU module and I/O modules.

Checking the dual-redundant switchover of the CPU module

1. Press the [START/STOP switch] on the front of the control-side CPU module once to stop it and make a switchover.
2. Press the [START/STOP switch] of the stopped CPU module again to restart it and place it in the standby mode.

SEE ALSO For more information about details on the START/STOP switch of the CPU module and the status display, refer to:

B4.2, “Processor module” in Hardware User's Guide (IM 32P06C10-01EN)

Checking the dual-redundant switchover of I/O modules

Using IOM Control Right Switching Tool, check the control right switchover of an AIO/DIO module in a dual-redundant configuration.

By using this tool, the AIO/DIO module on the control side will switch over to the standby side while the AIO/DIO module on the standby side will switch over to the control side.

This tool is launched from SENG.

SEE ALSO For more information about details on the IOM Control Right Switching Tool, refer to:

I4.7, “IOM Control Right Switching Tool” on page I4-83

I3. Setting system time

The system date and time can be set using the Adjust Time dialog box. The date and time specified in the Adjust Time dialog box are reflected on the SCS connected to the same domain and other SENGs. In the case of the CENTUM integration structure, the set date and time are also reflected on its FCS and HIS. Moreover, when multiple domains are connected through BCV or CGW and it so specified by the builder, the same date and time can be applied to the stations in the connected domains too.

The set date and time is applied to the following connected stations:

- Date/time of the local SENG (Windows date/time)
- Date/time of all SCS, FCS and HIS
- Date/time of other SENGs

If an HIS is connected, the time settings made on the HIS are applied to these stations as well.

IMPORTANT

- If Vnet/IP is applied as the control bus, using SNTP server standard time for time synchronization cannot change the system time from SENG and HIS.
- If V net is applied as the control bus, the Adjust Time dialog box should be used to set time regardless of what type of time synchronization is applied. When a V net network and a Vnet/IP network are connected through a V net router that is earlier than style S3, if the V net router system time transfer is set to [Transfer lower], the system time cannot be changed from an SENG or HIS on the V net. Moreover, if multiple domains are connected together through BCV or CGW, and if the BCV system time transfer is set to [Transfer lower], or the CGW is set to [Receive System Time], the system time cannot be changed from an SENG or HIS in the lower level domain.

Adjust Time dialog box

Click [Time Setup] button on the toolbar of the SCS Status Overview window or the SCS State Management window. The Adjust Time dialog box appears.

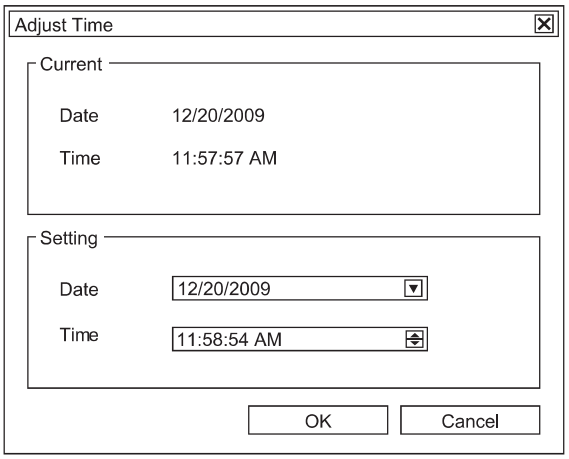

Figure I3-1 Adjust Time dialog box

The following items are displayed in the Adjust Time dialog box:

- Current
  The current system time is displayed in this area.

- Setting
  The system time can be set in this area.

How to set the system date and time

The system date and time can be adjusted using the spin boxes in the dialog box and then click the [OK] button. Click the [Cancel] button if you want to cancel the setting.
If you set the date/time, the date/time of the stations connected to the system are changed.
Note that the date/time format conforms to the Windows standard.

I4. Tools for operations and maintenance

You can use the following tools and functions for cause investigation when a system abnormality occurs, or while maintaining SCS devices.

- Forced I/O Viewer and Forced I/O Viewer Setup Tool
  You can use Forced I/O Viewer to collect and display the variables locked by using the forcing function.

  You can use Forced I/O Viewer Setup Tool to make the settings of the Forced I/O Viewer for collecting and displaying the information such as locked variables.
- Message Cache Tool
  You can use this tool for carrying out the collection settings of diagnostic information messages, which are displayed in the Diagnostic Information window or SOE Viewer.
- SOE Viewer
  You can use this tool to examine SOE events that are generated in the SCS.
- Master database offline download
  You can use this to perform offline download of the SENG master database to the SCS.
- NIU maintenance port setting tool
  You can use this tool for switching between the enable and disable status of the NIU maintenance port.
- IOM Download Tool
  You can use this tool to download the configuration information that is stored in the Master database to the I/O module.
- IOM Control Right Switching Tool
  You can use this tool for switching the control rights of AIO/DIO modules that are operating in a redundant configuration.

I4.1 Forced I/O Viewer function

Forced-I/O information is a collection of information such as variables that are locked in the Lock window of SENG by using the forcing function.

Forced I/O Viewer function is a function to display the forced-I/O information in a list. Forced-I/O information of multiple SCSs can be displayed collectively.

Forced I/O Viewer function consists of Forced I/O Viewer that displays the forced-I/O information and Forced I/O Viewer Setup Tool that makes the setting for collecting the forced-I/O information.

I4.1.1 Operation environment of Forced I/O Viewer function

This section describes the necessary licenses for using Forced I/O Viewer function and the operation environment such as conditions of SCS and SENG.

SEE ALSO

For more information about hardware requirements of the Forced I/O Viewer function, refer to:

A1.1, “Hardware requirements” in ProSafe-RS User’s Guide (IM 32P01B10-01EN)

For more information about software requirements of the Forced I/O Viewer function, refer to:

A1.2, “Software requirements” in ProSafe-RS User’s Guide (IM 32P01B10-01EN)

License

Forced I/O Viewer function runs in a computer that the following licenses has been assigned.

Table I4.1.1-1 Licenses necessary for Forced I/O Viewer function

Type	Name
RS4E5100	Safety System Engineering and Maintenance Function
RS4H2300	Forced I/O Viewer Package

SENG that the license of Safety System Engineering and Maintenance Function has been assigned can use Forced I/O Viewer Setup Tool and Forced I/O Viewer.

Computer that is connected to the control bus, such as HIS that the license of Forced I/O Viewer Package has been assigned can use Forced I/O Viewer.

IMPORTANT

Safety System Engineering and Maintenance Function and Forced I/O Viewer Package cannot be coexisted on the same computer.

TIP

To use Forced I/O Viewer in SENG, assign the license of Safety System Engineering and Maintenance Function instead of Forced I/O Viewer Package.

Conditions of SENG and SCS

The Forced I/O Viewer function runs in the following SENG and SCS.

For SCS that supports SIL 3

- SENG: SENG of software R4.05.00 or later
- SCS: SSC50, SSC57, SSC60, and S2SC70 of system program R4.05.00 or later

For SCS that supports SIL 2

- SENG: SENG of software R4.06.00 or later
- SCS: L1SC70 of system program R4.06.00 or later

I4.1.2 Forced-I/O information

Information, such as locked variables in various windows, that is displayed in Forced I/O Viewer is called forced-I/O information.

This section describes the display items of forced-I/O information.

Display items of forced-I/O information

The following forced-I/O information is displayed in the Forced I/O Viewer:

- Header
- Summary
- I/O Variables/Internal Variables
- SCS Link Transmission (sending and receiving)
- Inter-SCS Safety Communication (sending and receiving)
- Subsystem Communication
- Safety Subsystem Communication

In Forced I/O Viewer, a summary of forced-I/O information is displayed in brackets next to the item name of forced-I/O information. Detailed information about the forced-I/O information appears by expanding the item name of forced-I/O information.

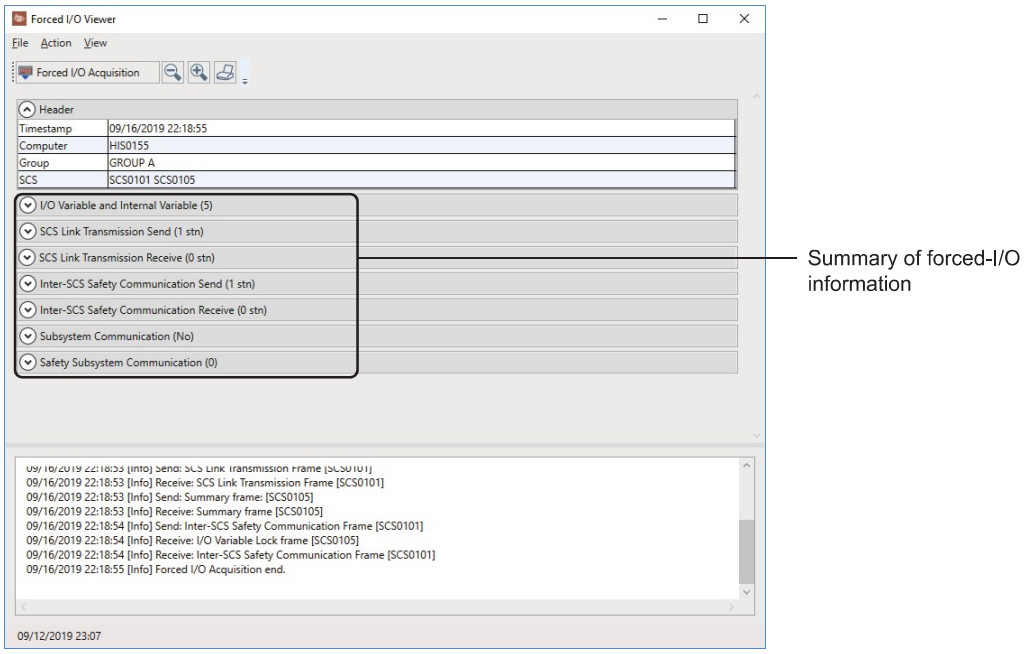

Figure I4.1.2-1 Summary of forced-I/O information

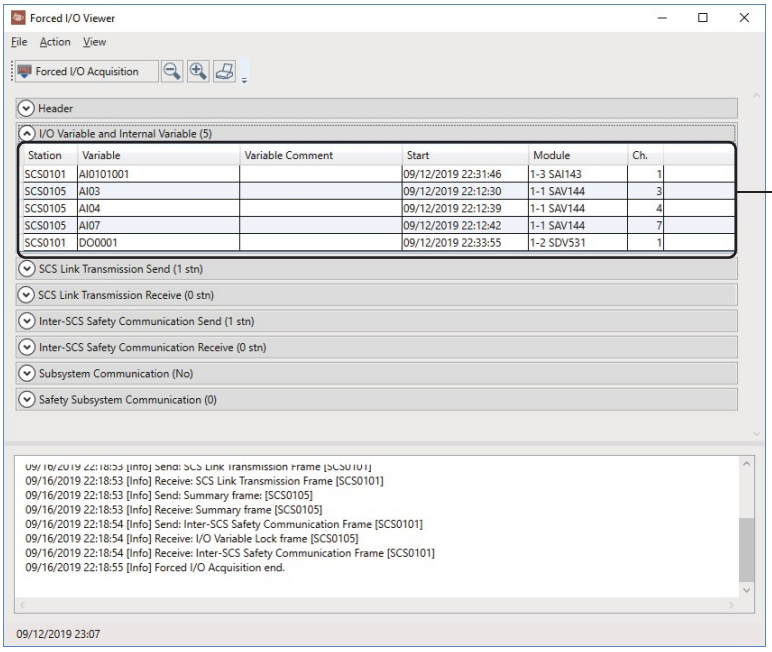

Figure I4.1.2-2 Detailed information of forced-I/O information

Header

The following table shows the header items of forced-I/O information.

Table I4.1.2-1 Header items of forced-I/O information

Item name	Description	Example
Timestamp	Date and time when the acquisition of forced-I/O information by Forced I/O Viewer was started	11/5/2019 19:30:10
Computer	Name of a computer that runs Forced I/O Viewer	HIS0164
Group	Name of a group where the forced-I/O information is acquired	Equipment 1
SCS	Station name of SCS that belongs to the group where the forced-I/O information is acquired	SCS0101 SCS0102

Summary

In the Summary of forced-I/O information, the number of locks and whether it is locked are displayed by each forced-I/O information. In the Summary, the forced-I/O information of multiple SCSs can be displayed collectively. The displayed number of locks is the total number of locked items. As for subsystem communication, whether it is locked or not is displayed. "Yes" is displayed when at least one subsystem communication is locked, and "No" is displayed when it is not locked.

Table I4.1.2-2 Items of Summary of forced-I/O information

Item name	Description
I/O Variable and Internal Variable	Total number of locked I/O variables and internal variables
SCS Link Transmission Send	Number of SCSs that have locked the sending data of SCS link transmission for local station
SCS Link Transmission Receive	Number of SCSs that have locked the receiving data of the SCS link transmission
Inter-SCS Safety Communication Send	Number of SCSs that have locked the sending data of inter-SCS safety communication for local station

Continues on the next page

Table I4.1.2-2 Items of Summary of forced-I/O information (Table continued)

Item name	Description
Inter-SCS Safety Communication Receive	Number of SCSs that have locked the receiving data of the inter-SCS safety communication
Subsystem Communication	Whether or not the subsystem communication is locked
Safety Subsystem Communication	Number of communication definitions locked in the safety subsystem communication

I/O Variable and Internal Variable

The I/O variable name and the internal variable name, which are locked from windows such as the I/O Lock window and the Dictionary View are displayed. The following table shows the items of I/O variable/internal variable.

Table I4.1.2-3 Items of I/O variable/internal variable of the forced-I/O information

Item name	Description	Example
Station	Station name of the locked SCS	SCS0101
Variable	I/O variable name and internal variable name	DO0001
Variable Comment	Comment entered for the variable	
Start	Date and time when the lock was started	11/5/2019 19:30:10
Module	I/O module name for the I/O variable (*1) (*2)	1-5 SDV531
Ch.	Channel number for the I/O variable (*1)	1

*1: This item is displayed for I/O variable.
*2: If it is FIO, the node number-slot number is added in front of the module name, and if it is N-IO, the node number-unit number-slot number is added.

SCS Link Transmission Send

The station name of SCS that have locked the sending data of the local station specified by using the SCS Link Transmission Lock window appears. The following table shows the SCS Link Transmission Send items.

Table I4.1.2-4 Items of SCS Link Transmission Send of the forced-I/O information

Item name	Description	Example
Station	Station name of the SCS that have locked the sending data	SCS0101
Instance	Instance name	sndb01
Instance Comment	Comment entered for the instance	
Start	Date and time when the lock was started	11/5/2019 19:30:10

SCS Link Transmission Receive

The station name of SCS that have locked the receiving data specified by using the SCS Link Transmission Lock window appears. The following table shows the SCS Link Transmission Receive items.

Table I4.1.2-5 Items of SCS Link Transmission Receive of the forced-I/O information

Item name	Description	Example
Station	Station name of the SCS that have locked the receiving data	SCS0101
Instance	Instance name	rcvi01

Continues on the next page

Table I4.1.2-5 Items of SCS Link Transmission Receive of the forced-I/O information (Table continued)

Item name	Description	Example
Instance Comment	Comment entered for the instance	
Start	Date and time when the lock was started	11/5/2019 19:30:10
Station (from)	Station name of the SCS from which received data is locked	SCS0102

Inter-SCS Safety Communication Send

Station name of SCS that have locked the sending data from the local station specified by using the Inter-SCS Communication Lock window appears. The following table shows the Inter-SCS Safety Communication Send items.

Table I4.1.2-6 Items of Inter-SCS Safety Communication Send of the forced-I/O information

Item name	Description	Example
Station	Station name of the SCS that have locked the sending data	SCS0101
Variable	Binding variable name	P0101001
Variable Comment	Comment entered for the binding variable	
Start	Date and time when the lock was started	11/5/2019 19:30:10
Instance	Instance name	PROD_R01

Inter-SCS Safety Communication Receive

Station name of the SCS that have locked the receiving data specified by using the Inter-SCS Communication Lock window appears. The following table shows the Inter-SCS Safety Communication Receive items.

Table I4.1.2-7 Display Items of Inter-SCS Safety Communication Receive of the forced-I/O information

Item name	Description	Example
Station	Station name of the SCS that have locked the receiving data	SCS0101
Variable	Binding variable name	C0102001
Variable Comment	Comment entered for the binding variable	
Start	Date and time when the lock was started	11/5/2019 19:30:10
Instance	Instance name	CONS_R01
Station (from)	Station name of the SCS from which received data is locked	SCS0102

Subsystem Communication

Communication module name that is locked by using the Communication I/O Lock window of subsystem communication mode appears. The following table shows the subsystem communication items.

Table I4.1.2-8 Items of subsystem communication of the forced-I/O information

Item name	Description	Example
Station	Station name of the SCS whose communication module is locked	SCS0101
Instance	Instance name	DI0000
Instance Comment	Comment entered for the instance	

Continues on the next page

Table I4.1.2-8 Items of subsystem communication of the forced-I/O information (Table continued)

Item name	Description	Example
Start	Date and time when the lock was started	11/5/2019 19:30:10
Module	Communication module name (*1)	3-1 ALR111

*1: Node number-slot number is added before the module name.

● Safety Subsystem Communication

PROFINET module name that is locked by using the Communication I/O Lock window of safety subsystem communication mode appears. The following table shows the safety subsystem communication items.

Table I4.1.2-9 Items of safety subsystem communication of the forced-I/O information

Item name	Description	Example
Station	Station name of the SCS whose communication module is locked	SCS0101
Instance	Instance name	DI0000
Instance Comment	Comment entered for the instance	
Start	Date and time when the lock was started	11/5/2019 19:30:10
Module	Communication module name (*1)	10-8 S2LP131
PN-Module	PROFINET module name	GS01_SAFE_RS

*1: Node number-slot number is added before the module name.

■ Displaying, printing, and saving the forced-I/O information

The forced-I/O information can be displayed in the main window of Forced I/O Viewer, and the displayed forced-I/O information can be printed and saved.

● Display

The forced-I/O information appears in the forced-I/O information display area of main window of Forced I/O Viewer. Each forced-I/O information item is displayed in tabular format. In this display, you can perform the following operations:

- Changing the order of items in the table
- Sorting the data of items in the table
- Changing the character size

SEE ALSO For more information about how to display the forced-I/O information, refer to:

"■ Step 1: Acquiring and displaying the forced-I/O information" on page I4-35

● Printing

Forced-I/O information displayed in the main window of Forced I/O Viewer can be printed. However, even if you change the order of items in the table in Forced I/O Viewer, it is not reflected in printing. The data is printed in the order in which they appear on the screen.

SEE ALSO For more information about how to print the forced-I/O information, refer to:

"■ Step 2: Printing the forced-I/O information" on page I4-36

Saving

Forced-I/O information displayed in the main window of Forced I/O Viewer can be saved in a CSV format file.

Even if you change the order of items in the table in Forced I/O Viewer, it is not reflected in the file. The data is saved in the order sorted by the mounting position.

SEE ALSO For more information about how to save the forced-I/O information, refer to:

"■ Step 3: Saving the forced-I/O information in a CSV format file" on page I4-37

I4.1.3 Grouping and registering SCS

By using Forced I/O Viewer Setup Tool, multiple SCSs can be grouped and registered.

By grouping and registering the SCSs, the forced-I/O information of all SCSs that belong to the group can be displayed collectively in the Forced I/O Viewer.

Specifications of grouping

The specifications of grouping are as follows:

- You can register multiple groups and give them unique names.
- The named groups are listed as options in Forced I/O Viewer. By selecting any group from the list, the forced-I/O information of SCSs that belong to the group can be displayed collectively.
- To list only the necessary groups as options in Forced I/O Viewer, you can assign groups to each computer that uses Forced I/O Viewer.
- One SCS can belong to multiple groups.
- One group can assign to multiple computers.
- Assignment of group cannot be changed for each user account of computer.

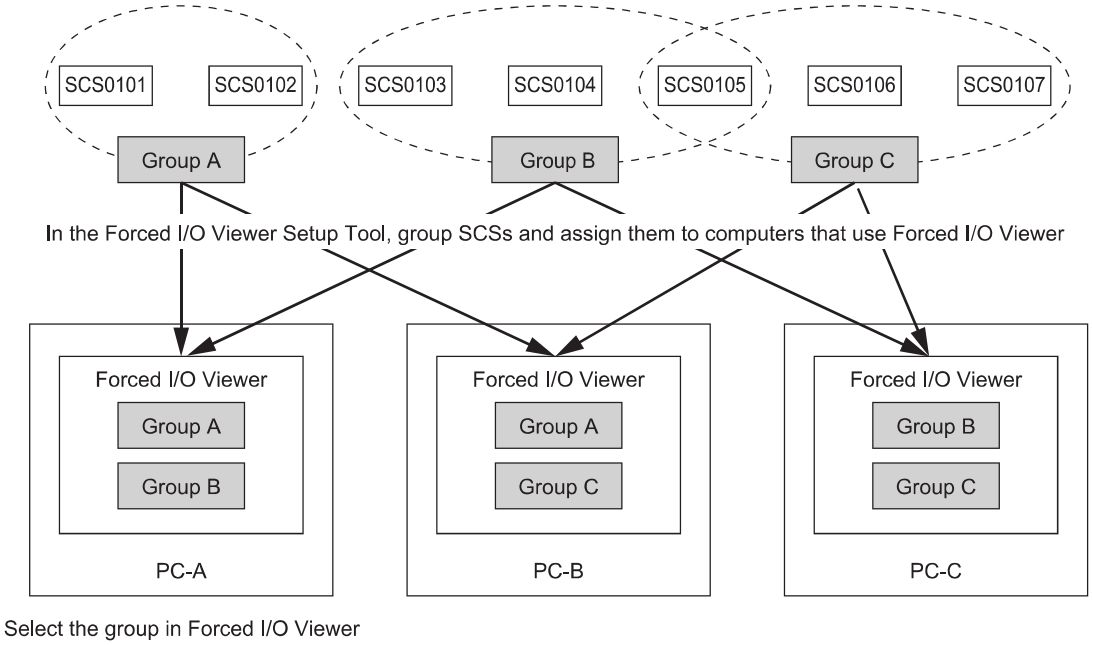

Figure I4.1.3-1 Example of SCS group

The number of groups and the specifications for the group name that can be registered in Forced I/O Viewer Setup Tool are as follows:

- The number of groups that can be registered: 32 groups
- Characters that can be used for the group name: Single-byte alphanumeric characters, space, under score, and hyphen

  The first character must be an alphabet and the last character must be other than a space.
- The number of characters for the group name: Up to 32 characters

I4.1.4 Distributing a registration file and SCS projects

To display the forced-I/O information, information that is obtained from SCS and the SCS project in SENG are required. The computer where the SCS projects are saved might be turned off, so files that saved the registered information necessary for obtaining the forced-I/O information by using Forced I/O Viewer Setup Tool (Registration file) and the SCS projects must be distributed to the computer that uses the Forced I/O Viewer.

The following figure shows the example of how to distribute the SCS projects.

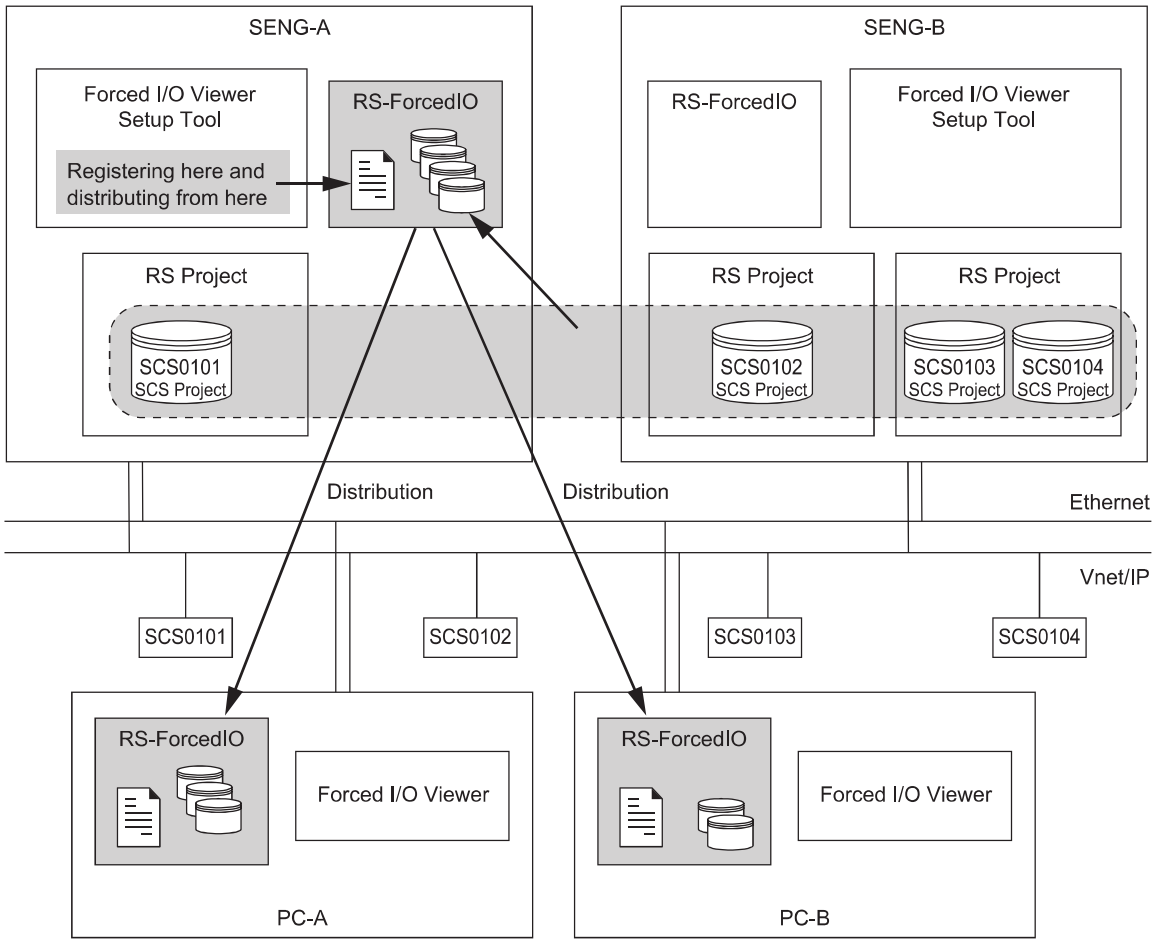

Figure I4.1.4-1 Distribution example of SCS projects

This figure is an example of distributing the registration file and SCS projects after you make the setting to use Forced I/O Viewer by each PC-A computer and PC-B computer from Forced I/O Viewer Setup Tool in the SENG-A computer.

The distribution destination is the following folder where a shared name RS-ForcedIO was assigned in the computer that uses Forced I/O Viewer.

```
<ProSafe-RS install drive>:\Program Files (x86)\ProSafe-RS\YOKOGAWA\hmi\ForcedIO
```

You can distribute the registration file and SCS projects together to all registered computers, distribute them to specific computers, or distribute only specific SCS projects.

For example, if a computer is added, distribute the registration file and SCS projects only to the added computer. If an SCS is added, distribute the registration file and the SCS projects of the added SCS to the computers which require to monitor the added SCS.

By distributing the registration file to other SENGs, you can also change and distribute the registration information by using the Forced I/O Viewer Setup Tool in other SENGs.

TIP

In the following cases, register the computer that uses Forced I/O Viewer Setup Tool from the Computer dialog box of Forced I/O Viewer Setup Tool and distribute the registration file and SCS projects to the computer itself:

- Using Forced I/O Viewer Setup Tool and Forced I/O Viewer on one computer
- Changing registration file from other SENGs

When the registration file is redistributed to a computer that has already been distributed, it is overwritten.

IMPORTANT

To distribute the registration file and SCS projects, setup specific to this function is required.

SEE ALSO

For more information about setup specific to this function, refer to:

B4.4, “Settings Required to Use the Forced I/O Viewer Function” in Installation Guide (IM 32P01C50-01EN)

For more information about how to distribute the registration file and SCS projects, refer to:

“■ Step 4: Distributing a registration file and SCS projects” on page I4-27

I4.1.5 Precautions for Forced I/O Viewer function

This section describes the precautions when using the Forced I/O Viewer function.

Display when forced-I/O information cannot be acquired

If the forced-I/O information cannot be acquired by the communication error or other reasons, a character that indicates an error is added after the station name of SCS of header.

Table I4.1.5-1 Error display of the header of forced-I/O information

Display	Error	Cause
(E)	Information cannot be acquired due to SCS.	• Communication error occurs.
(P)	Information cannot be acquired due to SCS project.	• SCS project is not distributed. • The distributed SCS project is different from the SCS project downloaded to SCS.

Example: SCS0101 SCS0102(E) SCS0103(P) SCS0104

In case (E) or (P) is added to the station name of SCS, the forced-I/O information of the corresponding SCS does not appear.

SEE ALSO For more information about display example of the forced-I/O information, refer to:

"● Display example of forced-I/O information" on page I4-35

When used computer is changed

In case of using the setup data by other computers or replacing a computer in which Forced I/O Viewer or Forced I/O Viewer Setup Tool is installed, perform the following operation:

- If the computer name is not changed
  Copy all files in the following folder and paste them to the target computer.

  ```
  <ProSafe-RS install drive>:\Program Files (x86)\ProSafe-RS\YOKOGAWA\hmi\ForcedIO
  ```

- If the computer name is changed
  - Copy all files in the following folder and paste them to the target computer.
    ```
    <ProSafe-RS install drive>:\Program Files (x86)\ProSafe-RS\YOKOGAWA\hmi\ForcedIO
    ```
  - Change the computer name in the Computer dialog box of Forced I/O Viewer Setup Tool.
  - By using the Distribution dialog box, distribute the registration file to the computer whose name has been changed.

I4.1.6 Screen configuration of Forced I/O Viewer Setup Tool

In Forced I/O Viewer Setup Tool, perform the following settings required to acquire and display the forced-I/O information in the Forced I/O Viewer.

- Registration of SCS:
  By using the SCS dialog box and the SCS Project Path dialog box, register the SCS and the SCS project path from which the forced-I/O information to be acquired.
- Registration of group:
  By using the Group dialog box, register groups and SCSs that belong to the group.
- Registration of computer:
  By using the Computer dialog box, register a computer that displays the forced-I/O information and groups to assign to the computer.
- Distribution of the registration file and SCS projects:
  By using the Distribution dialog box, distribute the registration file and the SCS projects to the computer.

The following figure shows a screen structure of Forced I/O Viewer Setup Tool.

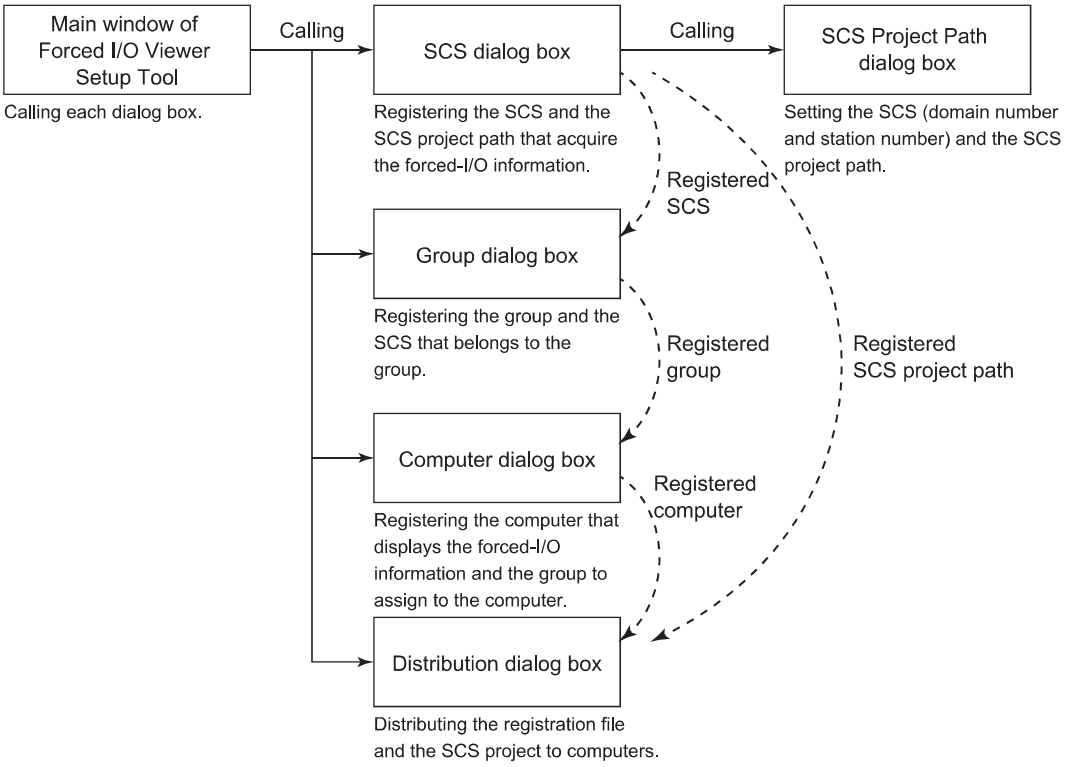

Figure I4.1.6-1 Screen configuration of Forced I/O Viewer Setup Tool

Main window

When you start the Forced I/O Viewer Setup Tool, main window of Forced I/O Viewer Setup Tool appears.

The following figure shows a main window of Forced I/O Viewer Setup Tool.

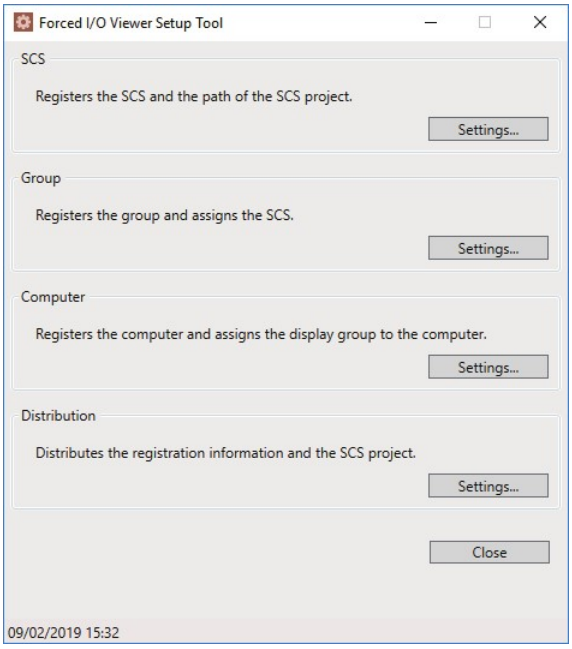

Figure I4.1.6-2 Main window of Forced I/O Viewer Setup Tool

IMPORTANT

Multiple Forced I/O Viewer Setup Tools cannot be started on one computer.

In the following cases, a message dialog box appears when you start the Forced I/O Viewer Setup Tool:

- When there are a saved registration file and a distributed registration file
- When there is only a distributed registration file

If a message dialog box appears, check the displayed message and select an appropriate registration file.

Buttons to open a dialog box

If you click [Settings...] in each area of the main window of Forced I/O Viewer Setup Tool, the corresponding dialog box opens.

Table I4.1.6-1 Buttons to open a dialog box in the main window

Area	Button	Description
SCS	Settings...	Opens the SCS dialog box.
Group	Settings...	Opens the Group dialog box.
Computer	Settings...	Opens the Computer dialog box.
Distribution	Settings...	Opens the Distribution dialog box.

Button	Description
Change...	Sets and changes the SCS project path displayed in the SCS list. If you select a row of SCS to set or change and click [Change...], the SCS Project Path dialog box appears.
Delete	Deletes the selected SCS from the SCS list.

● Buttons related to a whole dialog box

Table I4.1.6-6 Buttons for the whole SCS dialog box

Button	Description
Save	Saves the registration information and closes the dialog box.
Close	Closes the dialog box without saving the registration information.

■ SCS Project Path dialog box

The SCS Project Path dialog box is opened from the SCS dialog box. The SCS Project Path dialog box is used to add the SCS and set the SCS project path to the SCS list in the SCS dialog box.

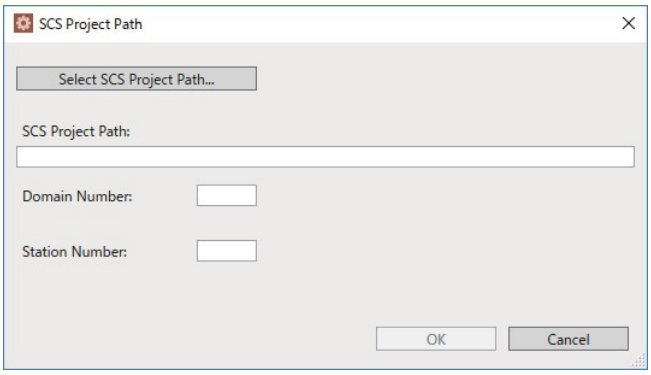

Figure I4.1.6-4 SCS Project Path dialog box

Take note on the following cautions when using the SCS Project Path dialog box:

- Make sure to set the domain number and the station number.
- Make sure to set the SCS project path before distributing the registration file and the SCS project from the Distribution dialog box.
- SCS project path can be selected from the Folder Selection dialog box after clicking [Add...] in the SCS dialog box, followed by clicking [Select SCS Project Path...] in the SCS Project Path dialog box. After a path is selected in the Folder Selection dialog box, the domain number and the station number of SCS automatically appear on the SCS Project Path dialog box.
- The domain number and the station number of SCS cannot be changed after registering them as a station name of SCS on the SCS list in the SCS dialog box.
  Delete that SCS station name from the SCS list in the SCS dialog box first and register a new SCS station name.
- If you display the SCS Project Path dialog box from [Change...] in the SCS dialog box, the domain number and the station number of the SCS appear, but you cannot edit them.

SCS Project Path

Table I4.1.6-7 Button of the SCS Project Path dialog box

Button	Description
Select SCS Project Path	Selects an SCS project path. If you click [Select SCS Project Path], the Folder Selection dialog box appears. In the Folder Selection dialog box, select a path in UNC format through the shared name RS-Projects. When you use an SCS project on the local computer, select a path in UNC format through the shared name RS-Projects as well. UNC format: `\\Computer name\Shared name\RS-Projects name\SCS project name` Example: `\\SENG0151\RS-Projects\MYRSPJT\SCS0101`

Table I4.1.6-8 Input area of the SCS Project Path dialog box

Display	Description
SCS Project Path:	Set the SCS project path. Perform either of the following operations: • Select a path in the Folder Selection dialog box that is displayed by clicking [Select SCS Project Path]. • Directly enter it. Set in UNC format (`\\Computer name\Shared name\RS-Projects name\SCS project name`) through the shared name RS-Projects. Example: `\\SENG0151\RS-Projects\MYRSPJT\SCS0101`
Domain Number:	Set the domain number of SCS.
Station Number:	Set the station number of SCS.

Buttons related to a whole dialog box

Table I4.1.6-9 Buttons for the whole SCS Project Path dialog box

Button	Description
OK	Reflects the settings in this dialog box to the SCS list in the SCS dialog box and closes the dialog box.
Cancel	Cancels the input and closes the dialog box.

Group dialog box

The Group dialog box is used to register the group name and the SCS that belong to the group.

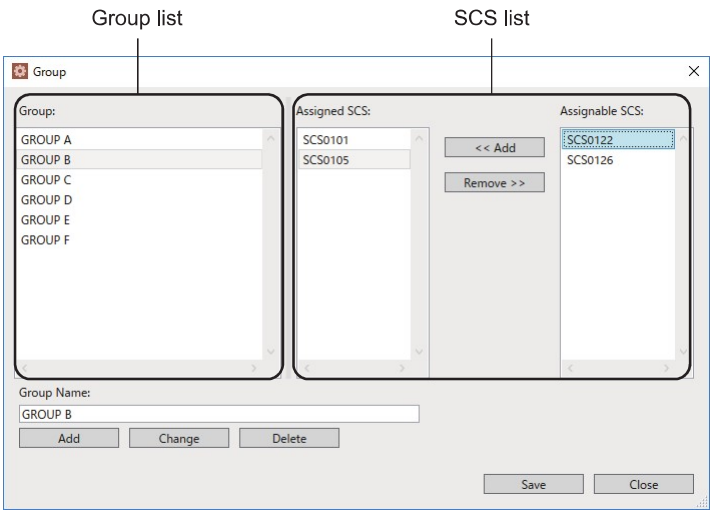

Figure I4.1.6-5 Group dialog box

SEE ALSO For more information about procedure of registering groups, refer to:

"■ Step 2: Registering groups" on page I4-24

Group list

If the Distribute check boxes in the Destination Computer list are selected but the Distribute check boxes in the SCS Project list are not selected, only the registration file is distributed.
Cancel	Stops the distribution.
Close	Closes the dialog box.

*1: This button acts as Cancel button during the distribution process.
*2: If the SCS belongs to the group that is assigned to the destination computer, these are distributed.

I4.1.7 Operations in Forced I/O Viewer Setup Tool

This section describes how to use the Forced I/O Viewer Setup Tool.

Preparation: Turning on the computer

In Forced I/O Viewer Setup Tool, the registration file and the SCS projects are distributed to the computer that uses Forced I/O Viewer. Before starting the setting of Forced I/O Viewer by using the Forced I/O Viewer Setup Tool, turn on the following computers. Make sure to not turn off the computers until the setting of Forced I/O Viewer Setup Tool is completed.

- Computer where the SCS projects are saved
- Destination computer

Step 1: Registering SCSs

IMPORTANT

If you distribute a registration file from another Forced I/O Viewer Setup Tool while using the Forced I/O Viewer Setup Tool, restart the Forced I/O Viewer Setup Tool that you are using.

Follow these steps to register the SCSs for which you want to acquire the forced-I/O information:

1. Start the Forced I/O Viewer Setup Tool.
   The main window appears.
2. Click [Settings...] in the SCS area.
   The SCS dialog box appears.
3. Click [Add...].
   The SCS Project Path dialog box appears.
4. Click [Select SCS Project Path...].
   The Folder selection dialog box appears.
5. Select the SCS project path.
   The selected path appears in the input area of SCS Project Path:. In addition, the domain number appears in the input area of Domain Number: and the station number appears in the input area of Station Number:.
6. Click [OK].
7. Repeat step 3 to 6 to add all SCSs to register.
8. Click [Save].
   The settings are saved.

Step 2: Registering groups

Follow these steps to register groups:

1. Start the Forced I/O Viewer Setup Tool.
   The main window appears.
2. Click [Settings...] in the Group area.
   The Group dialog box appears.
3. Enter a group name to be added in the input area of Group Name:, and click [Add].
   The entered group name is added to the Group list.

4. Repeat step 3 to add all groups you want to register to the Group list.
5. Select the target group from the Group list, select all SCSs to assign from the SCS list of Assignable SCS:, and then click [<<Add].
   The SCSs are added to the SCS list of Assigned SCS:.

TIP Multiple SCSs can be selected from the SCS list of Assignable SCS:.

6. Repeat step 5 to assign SCSs to all groups.
7. Click [Save].
   The settings are saved.

Changing the group name

Follow these steps to change the group name:

1. Open the Group dialog box.
2. From the Group list, select a group name to rename, change the name displayed in the input area of Group Name:, and then click [Change].

Deleting a group

Follow these steps to delete a group:

1. Open the Group dialog box.
2. From the Group list, select the group to delete, and click [Delete].
   The confirmation dialog box appears.
3. Click [OK].
   The group is deleted.

Assigning SCSs to a group

Follow these steps to assign SCSs to a group:

1. Open the Group dialog box.
2. Select the target group from the Group list, select all SCSs to assign from the SCS list of Assignable SCS:, and then click [<<Add].
   The assigned SCSs are added to the SCS list of Assigned SCS: of the selected group.

TIP Multiple SCSs can be selected from the SCS list of Assignable SCS:.

3. Repeat step 2 to assign SCSs to all groups.

Removing the assigned SCSs from the group

Follow these steps to remove the assigned SCSs from the group:

1. Open the Group dialog box.
2. Select the target group from the Group list, select SCSs that you want to remove the assignment from the SCS list of Assigned SCS:, and then click [Remove>>].
   The SCSs are removed from the SCS list of Assigned SCS: of the selected group.

TIP Multiple SCSs can be selected from the SCS list of Assigned SCS:.

Saving the settings

Perform this step to save the settings:

- Click [Save].

The settings are saved.

Step 3: Registering computers

Follow these steps to register computers that use the Forced I/O Viewer:

1. Start the Forced I/O Viewer Setup Tool.
   The main window appears.
2. Click [Settings...] in the Computer area.
   The Computer dialog box appears.
3. Enter a computer name to be added in the input area of Computer Name:, and click [Add].
   The entered computer name is added to the Computer list.
4. Repeat step 3 to add all computers you want to register to the Computer list.
5. Select the target computer from the Computer list, select all groups to assign from the Group list of Assignable Group:, and then click [<<Add].
   The assigned groups are added to the Group list of Assigned Group: of the selected computer.

TIP Multiple groups can be selected from the Group list of Assignable Group:.

6. Repeat step 5 to assign groups to all computers.
7. Click [Save].
   The settings are saved.

Changing the computer name

Follow these steps to change the registered computer name:

1. Open the Computer dialog box.
2. From the Computer list, select a computer name to rename, change the name displayed in the input area of Computer Name:, and then click [Change].

Deleting a computer

Follow these steps to delete a registered computer:

1. Open the Computer dialog box.
2. Select a computer to delete from the Computer list, and click [Delete].
   The confirmation dialog box appears.
3. Click [OK].
   The computer is deleted.

Assigning groups to a computer

Follow these steps to assign groups to a computer:

1. Open the Computer dialog box.
2. Select the target computer from the Computer list, select all groups to assign from the Group list of Assignable Group:, and then click [<<Add].
   The assigned groups are added to the Group list of Assigned Group: of the selected computer.

TIP Multiple groups can be selected from the Group list of Assignable Group:.

3. Repeat step 2 to assign groups to all computers.

Removing the assigned groups from the computer

Follow these steps to remove the assigned groups from the computer:

1. Open the Computer dialog box.
2. Select the target computer from the Computer list, select groups that you want to remove the assignment from the Group list of Assigned Group:, and then click [Remove>>].
   The groups are removed from the Group list of Assigned Group: of the selected computer.

TIP

Multiple groups can be selected from the Group list of Assigned Group:.

Saving the settings

Perform this step to save the settings:

- Click [Save].
  The settings are saved.

Step 4: Distributing a registration file and SCS projects

There are several ways to distribute a registration file and SCS projects to a computer.

This section describes each method.

IMPORTANT

You cannot distribute to the computer where Forced I/O Viewer is collecting forced-I/O information. If you attempt distribution, an error will result. Distribution is also not possible while the Forced I/O Acquisition (Select) dialog box or Forced I/O Acquisition (Start) dialog box is displayed on Forced I/O Viewer.

Distributing a registration file and SCS projects to all computers

Follow these steps to distribute a registration file and SCS projects to all computers:

1. Start the Forced I/O Viewer Setup Tool.
   The main window appears.
2. Click [Settings...] in the Distribution area.
   The Distribution dialog box appears.
3. Click [Select All] under the Destination Computer list.
   The check boxes of all Distribute columns in the Destination Computer list are selected.
4. Click [Select All] under the SCS Project list.
   The check boxes of all Distribute columns in the SCS Project list are selected.
5. Click [Distribute].
   The distribution result for each computer appears in the Result column of Destination Computer list. If there is an error, the error information appears in the message display area.

Distributing a registration file and SCS projects by selecting a specific computer

When a computer is added or a distribution to a specific computer is failed, you can distribute a registration file and SCS projects to the specific computer.

Follow these steps to distribute a registration file and SCS projects to the specific computer:

1. Start the Forced I/O Viewer Setup Tool.

The main window appears.

2. Click [Settings...] in the Distribution area.
   The Distribution dialog box appears.
3. Click [Deselect All] under the Destination Computer list.
   The check boxes of all Distribute columns in the Destination Computer list are cleared.
4. Select the check boxes of Distribute columns in the Destination Computer list that you want to distribute.
5. Click [Select All] under the SCS Project list.
   The check boxes of all Distribute columns in the SCS Project list are selected.
6. Click [Distribute].
   The distribution result for each computer appears in the Result column of Destination Computer list. If there is an error, the error information appears in the message display area.

Distributing selected specific SCS projects to all computers

When you add an SCS, when you re-build SCS project data with SENG and download it to the SCS after the distribution, or when it fails the distribution of only specific SCS projects, you can distribute the specific SCS projects to all computers.

Follow these steps to distribute the specific SCS projects to all computers:

1. Start the Forced I/O Viewer Setup Tool.
   The main window appears.
2. Click [Settings...] in the Distribution area.
   The Distribution dialog box appears.
3. Click [Select All] under the Destination Computer list.
   The check boxes of all Distribute columns in the Destination Computer list are selected.
4. Click [Deselect All] under the SCS Project list.
   The check boxes of all Distribute columns in the SCS Project list are cleared.
5. Select the check boxes of Distribute columns in the SCS Project list that you want to distribute.
6. Click [Distribute].
   The distribution result for each computer appears in the Result column of Destination Computer list. If there is an error, the error information appears in the message display area.

Distributing only the registration file to all computers

When the settings are changed in the Group dialog box or the Computer dialog box, you can distribute only the registration file to all computers.

Follow these steps to distribute only the registration file to all computers:

1. Start the Forced I/O Viewer Setup Tool.
   The main window appears.
2. Click [Settings...] in the Distribution area.
   The Distribution dialog box appears.
3. Click [Select All] under the Destination Computer list.
   The check boxes of all Distribute columns in the Destination Computer list are selected.
4. Click [Deselect All] under the SCS Project list.
   The check boxes of all Distribute columns in the SCS Project list are cleared.
5. Click [Distribute].
   The confirmation dialog box appears.

6. Click [Yes].
   The distribution result for each computer appears in the Result column of Destination Computer list. If there is an error, the error information appears in the message display area.

I4.1.8 Screen configuration of Forced I/O Viewer

The Forced I/O Viewer acquires and displays the forced-I/O information.

The following figure shows a screen configuration of the Forced I/O Viewer.

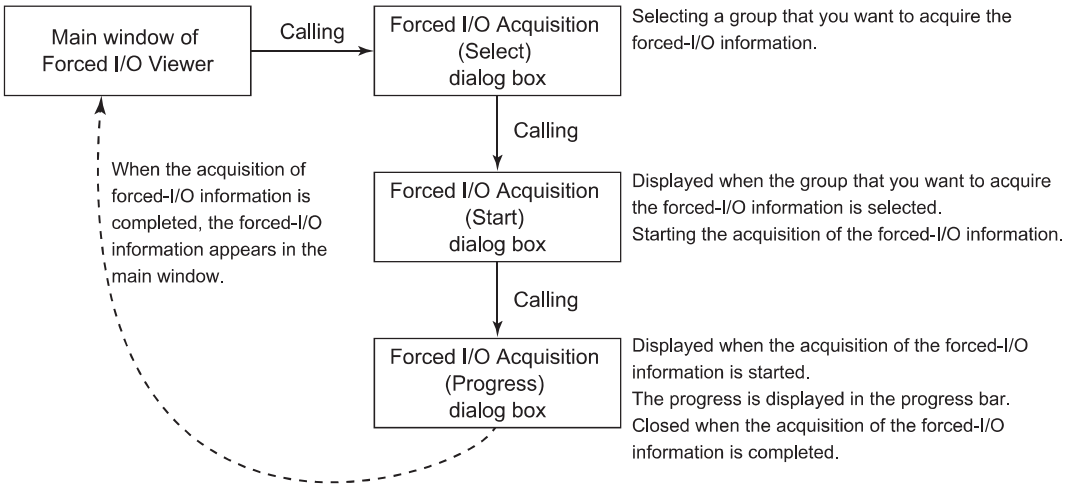

Figure I4.1.8-1 Screen configuration of Forced I/O Viewer

Main window

When you start the Forced I/O Viewer, main window of Forced I/O Viewer appears.

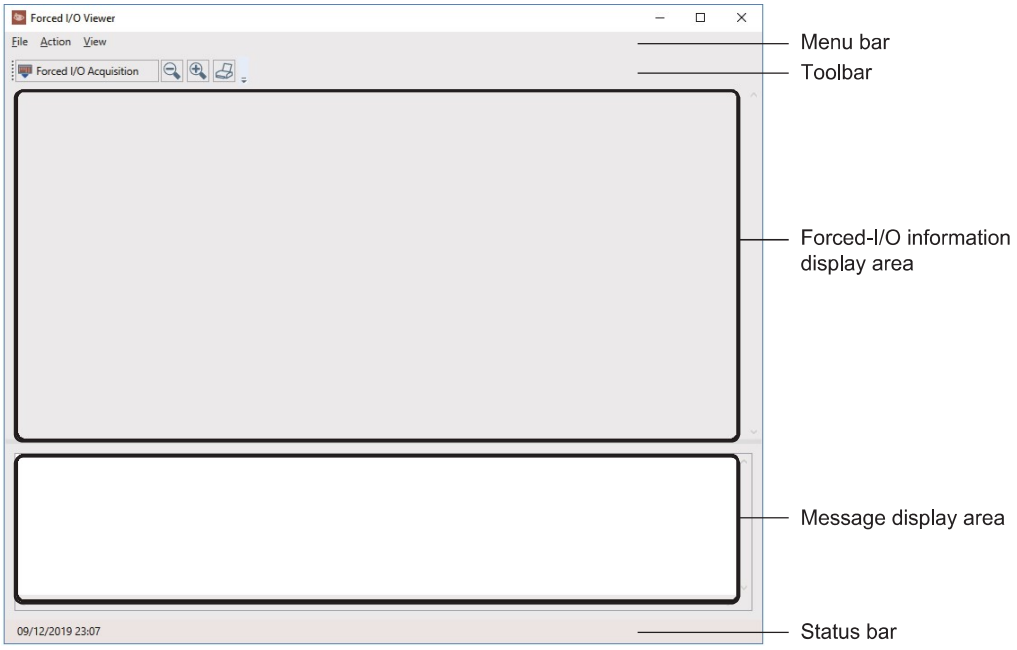

Figure I4.1.8-2 Main window of Forced I/O Viewer

Multiple Forced I/O Viewers cannot be started on one computer.

If the Forced I/O Viewer is started on the computer where the registration file and SCS projects are not distributed from the Forced I/O Viewer Setup Tool, a message dialog box appears, and the Forced I/O Viewer exits.

Menu bar

In the Menu bar, File menu, Action menu, and View menu are displayed.

Table I4.1.8-1 File menu

Item	Description
Print...	Prints the forced-I/O information shown in the forced-I/O information display area.
Output CSV File...	Outputs the forced-I/O information shown in the forced-I/O information display area to CSV format file.
Exit	Exits the Forced I/O Viewer.

Table I4.1.8-2 Action menu

Item	Description
Forced I/O Acquisition...	Opens the Forced I/O Acquisition (Select) dialog box.

Table I4.1.8-3 View menu

Item	Description
Zoom in	Enlarges the character size in the forced-I/O information display area.
Zoom out	Reduces the character size in the forced-I/O information display area.

Toolbar

There are toolbars of Forced I/O Acquisition, Zoom In, Zoom out, and Print.

Forced-I/O information display area

In the forced-I/O information display area, a header that is the handling information of forced-I/O information acquisition and the acquired forced-I/O information appear.

Summary is displayed in the title of forced-I/O information. If you click the title of forced-I/O information, the detailed information appears. If you click the title of forced-I/O information while the detailed information is displayed, the detailed information closes.

The following table shows the classification and the title of forced-I/O information.

Table I4.1.8-4 Classification of the forced-I/O information area and the title of forced-I/O information

Classification	Title of forced-I/O information
Header	Header
I/O variable and Internal variable	I/O Variable and Internal Variable (Number of locks)
SCS Link Transmission Send	SCS Link Transmission Send (Number of locks)
SCS Link Transmission Receive	SCS Link Transmission Receive (Number of locks)
Inter-SCS Safety Communication Send	Inter-SCS Safety Communication Send (Number of locks)
Inter-SCS Safety Communication Receive	Inter-SCS Safety Communication Receive (Number of locks)
Subsystem communication	Subsystem Communication (Locked/Not locked)
Safety subsystem communication	Safety Subsystem Communication (Number of locks)

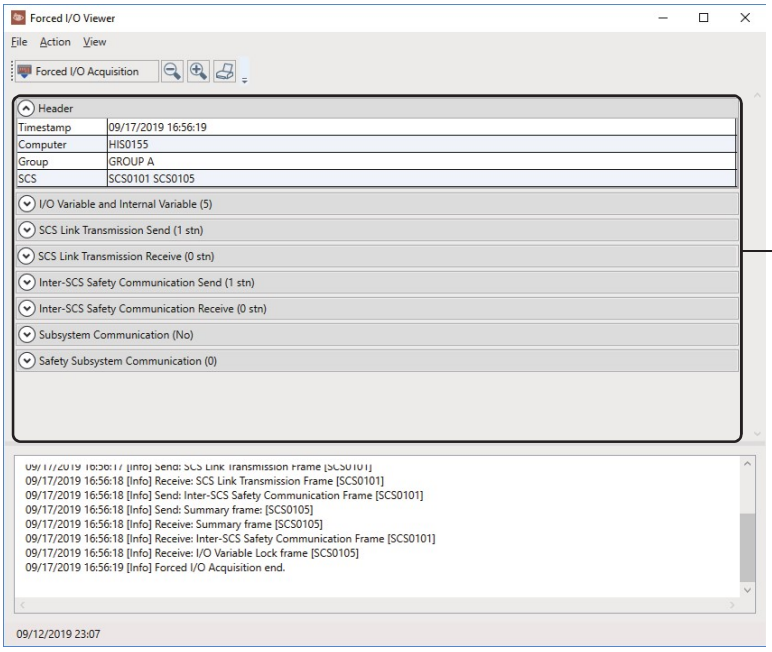

Figure I4.1.8-3 Forced-I/O information display area of main window

The specifications of forced-I/O information display area are as follows:

- The forced-I/O information display area is not displayed when the forced-I/O information is not acquired, such as when soon after starting the Forced I/O Viewer.
- When the acquisition of forced-I/O information is completed, the header and the forced-I/O information appear in the forced-I/O information display area.
- The details of forced-I/O information are displayed in tabular format as detailed information.
- If you click the column title of the table of detailed information, the table can be sorted in ascending or descending order. If you drag the column title and drop it on the desired position, the position of the column can be changed.
- If there is no locked item, “0” is displayed for the number of locks and “No” is displayed for the Locked/Not locked status in the summary of forced-I/O information. In addition, the table of detailed information is not displayed, but "not exist" is displayed.

Message display area

During the acquisition of forced-I/O information, the progress of the action appears in the message display area.

Status bar

The status bar displays the date and time that the registration file loaded to the Forced I/O Viewer was updated.

Forced I/O Acquisition (Select) dialog box

The Forced I/O Acquisition (Select) dialog box is used to select a group that displays the forced-I/O information. When the Forced I/O Viewer is started, it is automatically displayed on top of the main window.

The group names assigned to that computer in the Computer dialog box of Forced I/O Viewer Setup Tool are listed. From that list, select a group that you want to display the forced-I/O information.

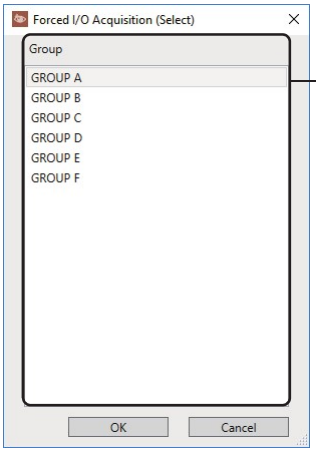

Figure I4.1.8-4 Forced I/O Acquisition (Select) dialog box

● Group list

Table I4.1.8-5 Group list of the Forced I/O Acquisition (Select) dialog box

Display	Description
Group	Names of groups (*1) are listed. • From this list, select a group that you want to display the forced-I/O information. • Multiple selection is not available.

*1: The names of groups assigned to that computer in the Computer dialog box of Forced I/O Viewer Setup Tool

● Buttons related to a whole dialog box

Table I4.1.8-6 Buttons for the whole Forced I/O Acquisition (Select) dialog box

Button	Description
OK	Fixes the selected group in the Group list and displays the Forced I/O Acquisition (Start) dialog box.
Cancel	Closes the dialog box without starting the acquisition of the forced-I/O information.

■ Forced I/O Acquisition (Start) dialog box

The Forced I/O Acquisition (Start) dialog box appears after the group is fixed in the Forced I/O Acquisition (Select) dialog box. This dialog box is used when starting the acquisition of the forced-I/O information.

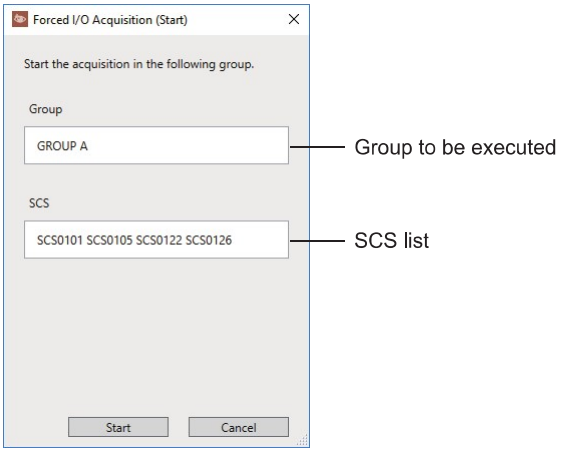

Figure I4.1.8-5 Forced I/O Acquisition (Start) dialog box

Details displayed in the dialog box

Table I4.1.8-7 Details displayed in the Forced I/O Acquisition (Start) dialog box

Display	Description
Group	The group name that will start the acquisition appears. The group name selected from the Group list in the Forced I/O Acquisition (Select) dialog box appears.
SCS	Station names of SCSs (*1) that belong to the group are listed.

*1: The SCSs assigned to that group in the Group dialog box of Forced I/O Viewer Setup Tool

Buttons related to a whole dialog box

Table I4.1.8-8 Buttons for the whole Forced I/O Acquisition (Start) dialog box

Button	Description
Start	Starts the acquisition of the forced-I/O information.
Cancel	Closes the dialog box without starting the acquisition of the forced-I/O information.

Forced I/O Acquisition (Progress) dialog box

The Forced I/O Acquisition (Progress) dialog box appears during the acquisition of forced-I/O information.

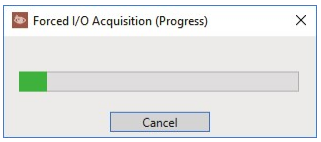

Figure I4.1.8-6 Forced I/O Acquisition (Progress) dialog box

Table I4.1.8-9 Button for the whole Forced I/O Acquisition (Progress) dialog box

Button	Description
Cancel	Stops the acquisition of the forced-I/O information.

I4.1.9 Operations in Forced I/O Viewer

This section describes how to use the Forced I/O Viewer.

Step 1: Acquiring and displaying the forced-I/O information

1. Start the Forced I/O Viewer.
   The main window and the Forced I/O Acquisition (Select) dialog box are displayed by overlapping.

TIP

- To display the Forced I/O Acquisition (Select) dialog box again, click [Forced I/O Acquisition] in the main window.
- If a registration file is distributed from Forced I/O Viewer Setup Tool while the Forced I/O Viewer is used, when the Forced I/O Acquisition (Select) dialog box is displayed, the contents of the distributed registration file are reflected.

2. Select the group that you want to acquire the forced-I/O information from the Group list, and click [OK].
   The Forced I/O Acquisition (Start) dialog box appears.
3. After you confirm that the selected group name is displayed in the Group, click [Start].
   Acquisition of the forced-I/O information is started, and the Forced I/O Acquisition (Progress) dialog box appears.

   When the acquisition of the forced-I/O information is completed, the Forced I/O Acquisition (Progress) dialog box closes. The acquired forced-I/O information appears in the forced-I/O information display area of main window.

TIP

To stop the acquisition while acquiring the forced-I/O information, click [Cancel].

4. Click the title of forced-I/O information that you want to display the detailed information.
   The table of detailed information appears.

Display example of forced-I/O information

- When the information was successfully acquired:
  The following figure shows the display example when the information was successfully acquired from SCS and SCS project.

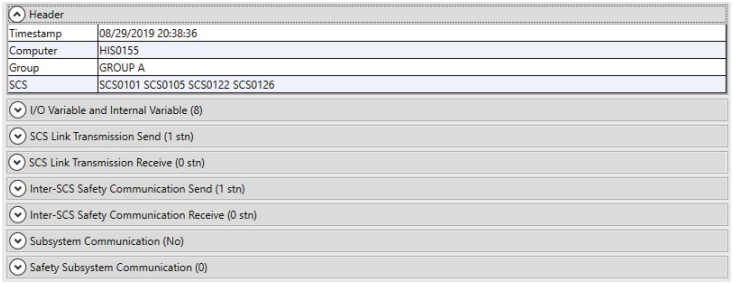

Figure I4.1.9-1 Display example when the information was successfully acquired

- When the information could not be acquired due to SCS:
  The following figure shows the display example when the information could not be acquired from SCS by the communication error or other reasons.

  When the information could not be acquired from SCS, (E) is added to the station name of SCS.

  The following figure shows the example of failure in SCS0101 and SCS0102. The failed SCS information is not output to the summary and the detailed information.

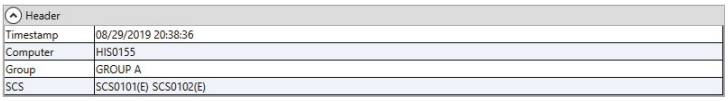

Figure I4.1.9-2 Display example when the information could not be acquired due to SCS

- When the information could not be acquired due to SCS project:
  The following figure shows the display example when the information could not be acquired from SCS project.

  When the information could not be acquired from SCS project, (P) is added to the station name of SCS.

  The following figure shows the example of failure in SCS0101 and SCS0102. The failed SCS information is not output to the summary and the detailed information.

  This situation occurs when the latest SCS project is not distributed. If this situation occurs, distribute the latest SCS project from the Forced I/O Viewer Setup Tool.

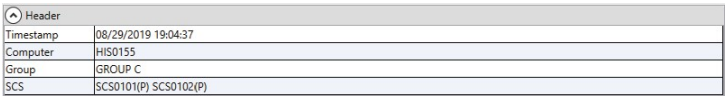

Figure I4.1.9-3 Display example when the information could not be acquired due to SCS project

Step 2: Printing the forced-I/O information

When the forced-I/O information is displayed in the forced-I/O information display area, the forced-I/O information can be printed.

Follow these steps to print the forced-I/O information:

1. Select [File] > [Print] from the main window of Forced I/O Viewer.
   The Print dialog box appears.
2. Set a printer to output and the printing conditions, and click [Print].
   The forced-I/O information is printed.

Example of printing the forced-I/O information

- When the information was successfully acquired:
  The following figure shows the example of printing when the information was successfully acquired from SCS and SCS project.

ProSafe-RS Forced I/O Viewer

Timestamp : 11/05/2019 21:00:10
Computer : HIS0155
Group : GROUP B
Station : SCS0101 SCS0105 SCS0121 SCS0126

Summary:

I/O Variable and Internal Variable (Variable)	5
SCS Link Transmission Send (Station)	1
SCS Link Transmission Receive (Station)	1
Inter-SCS Safety Communication Send (Station)	7
Inter-SCS Safety Communication Receive (Station)	7
Subsystem Communication (Exist)	Yes
Safety Subsystem Communication (PN-Module)	4

I/O Variable and Internal Variable:

Station	Start	Module	Ch.
Variable Name			
Variable Comment			
SCS0102	11/05/2019 21:00:10	2-3 SDV144	1
DI0001XXXXXXXXXXXXXXXXXXXXXXXXXXXX			
DI0001VariableCommentXXXXXXXXXXX			
SCS0102	11/05/2019 21:00:10	2-3 SDV144	2
DI0002XXXXXXXXXXXXXXXXXXXXXXXXXXXX			
DI0002VariableCommentXXXXXXXXXXX			

Figure I4.1.9-4 Example of printing when the information was successfully acquired

- When the information could not be acquired due to SCS:
  The same information as the screen is printed.
- When the information could not be acquired due to SCS project:
  The same information as the screen is printed.

Step 3: Saving the forced-I/O information in a CSV format file

When the forced-I/O information is displayed in the forced-I/O information display area, the forced-I/O information can be saved in a CSV format file.

Follow these steps to save the forced-I/O information in a CSV format file.

1. Select [File] > [Output CSV File] from the main window of Forced I/O Viewer.
   The Save As dialog box appears.
2. Set the file name and the save destination, and click [Save].
   The forced-I/O information is saved in a CSV format file.

I4.2 Message Cache Tool

Diagnostic information messages displayed in the Diagnostic Information window, and SOE event messages and trip information displayed in the SOE Viewer, are collected from SCS stations using the Message Cache Service.

Message Cache Tool is used to display the status of collecting diagnostic information messages, SOE event information and tripping information, to make various settings of Message Cache Service and to maintain cache data collected by Message Cache Service including storage and deletion. It also allows checking the volume of cache data stored on the hard disk.

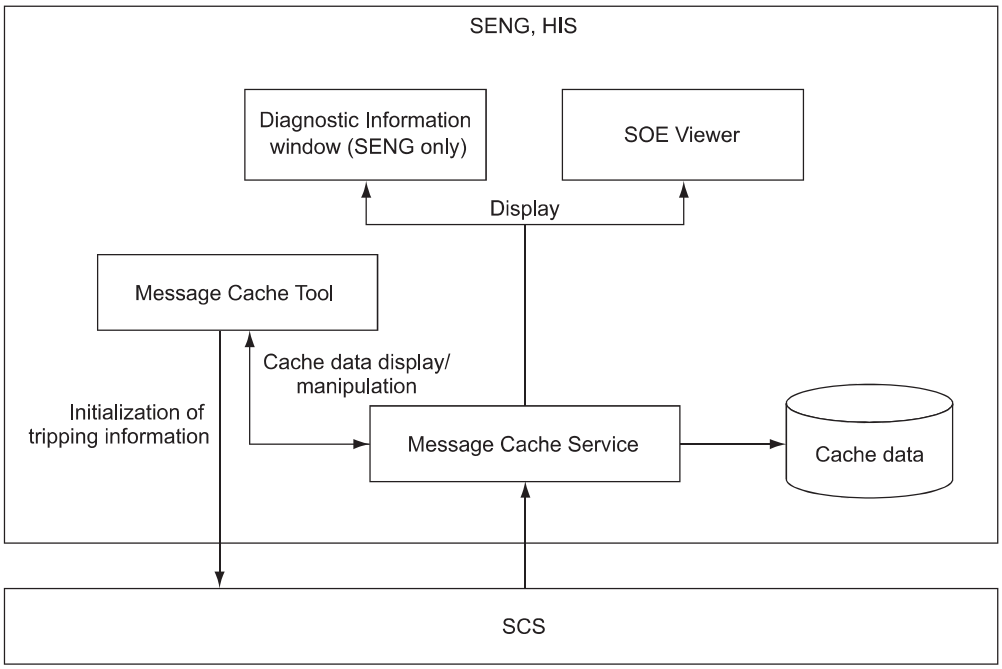

Figure I4.2-1 Positioning of Message Cache Tool

Message Cache tool

Message Cache Tool allows you to make the following settings and maintenance operations:

- Setting stations
  This setting is required only when caching the messages collected by other stations. The settings for the local station were completed beforehand.
- Acquisition setting
  Make settings related to the SCS selected as the target of collection by Message Cache Service and the volume of the hard disk to be used
- Display of data acquisition status
  Display acquisition status of diagnostic information messages, SOE event messages and tripping information collected from the SCS by Message Cache Service
- Initialization of tripping information
  Initialize tripping information in the SCS
- Manipulation of cache data
  Store cache data collected by Message Cache Service in a different folder or delete the data

How to launch Message Cache Tool

1. Start Message Cache Tool.

Before the tool is launched, a password check for SCS Maintenance Support Tool is performed.

2. Enter your password.
When Windows authentication mode is set, enter a password. When the Access Control and Operation History Management Package is applied, enter the name and password of the engineer.

Message Cache Tool window

The Message Cache Tool window is shown in the figure as follows.

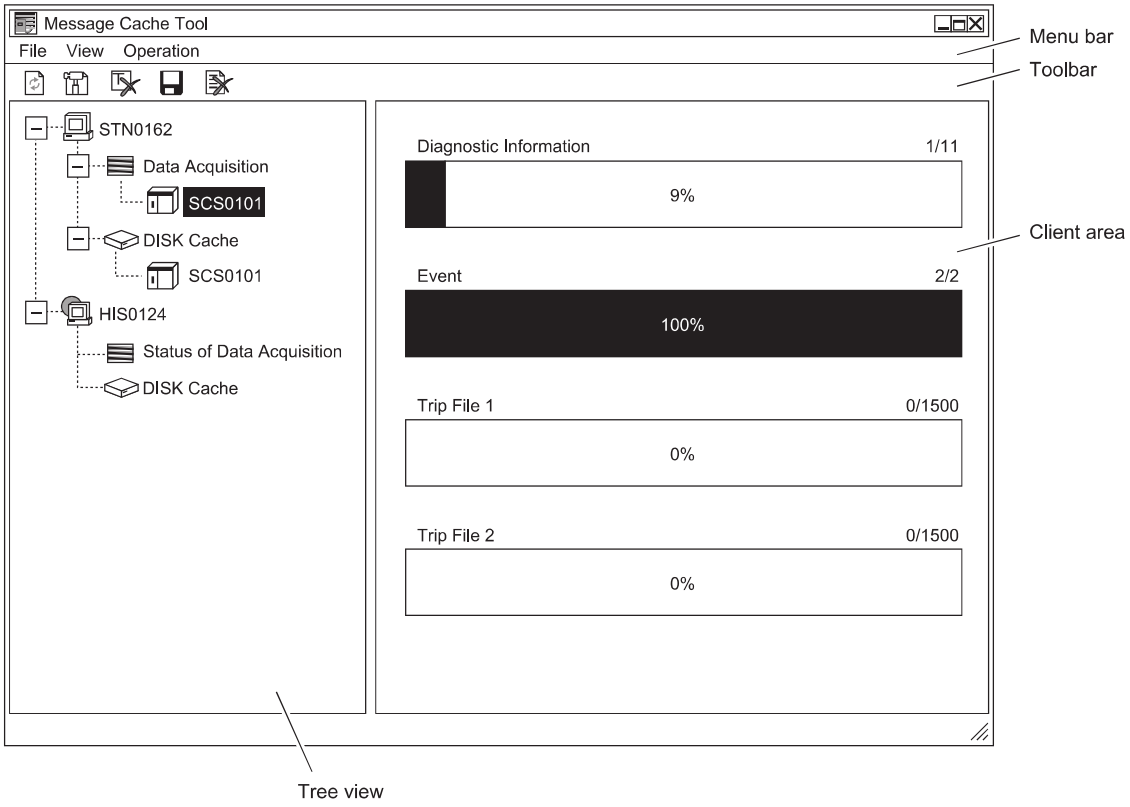

Figure I4.2-2 Data Acquisition Status window of Message Cache Tool

The components of the window are explained next.

Menu bar

The following menus are provided on the menu bar:

- [File] Menu
- [View] Menu
- [Operation] Menu

Menu items provided on each menu are explained as follows.

File menu

Table I4.2-1 File menu

Menu item	Function
Setup	Display a dialog box for making various settings related to Message Cache Service.
Close	Close the Message Cache Tool.

View menu

Table I4.2-2 View menu

Menu item	Function
Toolbar	Hide/show the toolbar
Status Bar	Hide/show the status bar
Station Setup	Display the Station Setup dialog box for selecting one or more stations on which Message Cache Service should run
Update	Update the window display to the latest status

Operation menu

Table I4.2-3 Operation menu

Menu item	Function
Initialize Trip Information	Display the Initialize Trip Information dialog box for the initialization of tripping information maintained in SCS.
Save Disk Cache	Display the Save Disk Cache dialog box for saving the contents of the disk cache in an arbitrary folder.
Delete Disk Cache	Display the Delete Disk Cache dialog box for deleting the contents of the disk cache.

IMPORTANT

Do not delete the disk cache. If disk cache is deleted by selecting the [Delete Disk Cache] menu, the cached diagnostic messages and the SOE events will be lost and cannot be displayed.

SEE ALSO

For more information about Initialize Trip Information dialog box, refer to:

I4.2.5, “Initialization of tripping information” on page I4-48

For more information about the Save DISK Cache dialog box, refer to:

I4.2.6, “Saving disk cache” on page I4-49

Toolbar

The following buttons are provided on the toolbar.

Table I4.2-4 Toolbar buttons

Button	Name	Description
	Update	Same function as [Update] on the [View] menu
	Setup	Same function as [Setup] on the [File] menu
	Initialize Trip Information	Same function as [Initialize Trip Information] on the [Operation] menu
	Save Disk Cache	Same function as [Save Disk Cache] on the [Operation] menu
	Delete Disk Cache	Same function as [Delete Disk Cache] on the [Operation] menu

IMPORTANT

Do not delete the disk cache. If disk cache is deleted by selecting the menu [Delete Disk Cache], the cached diagnostic messages and the SOE events will be lost and cannot be displayed.

Tree view

The tree view displays a list of stations (SENG, HIS) on which Message Cache Service runs.

The following items are displayed for each station.

Table I4.2-5 Display of tree view

Item	Description
Data Acquisition	Click this item to display a list of SCSs that are targets of engineering or operation and monitoring on each station (SENG or HIS). Click the name of an SCS to display the acquisition status of data of the selected SCS in the client area.
DISK Cache	Click this item to display a list of SCSs that are targets of engineering or operation and monitoring on each station (SENG or HIS). Click [Disk Cache] to display the disk cache usage status (all) for the entire station in the client area on the right side. Click the name of an SCS to display the disk cache usage status (SCS) of the selected SCS in the client area.

Client area

The display in the client area varies depending on the target selected in the tree view.

Table I4.2-6 Display of Client area

Selected target	Display
Data Acquisition- SCS	Displays the data acquisition status for each SCS.
Disk Cache	Displays the disk cache usage status (all) for all SCSs defined as data acquisition targets.
Disk Cache - SCS	Displays the disk cache usage status (SCS) for each SCS.

SEE ALSO

For more information about the details displayed in the data acquisition status, refer to:

I4.2.3, “Displaying data acquisition status” on page I4-44

For more information about the details displayed in the disk cache usage status, refer to:

I4.2.4, “Displaying disk cache usage status” on page I4-45

I4.2.1 Setting stations

This setting is required only when caching the messages collected by other stations. The settings for the local station were completed beforehand.

Displaying the Station Setup dialog box

Select [Station Setup] from the [View] menu; the Station Setup dialog box appears.

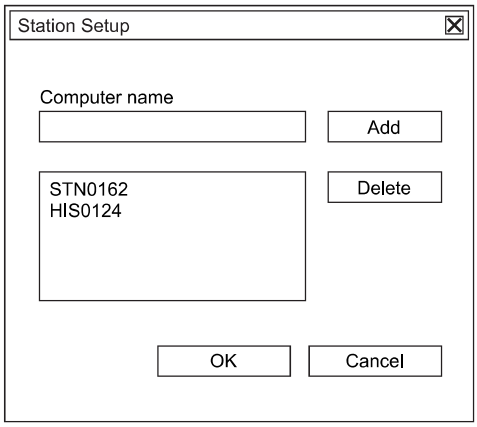

Figure I4.2.1-1 Station Setup dialog box

Station setting operations

Adding stations

1. To add the station (SENG or HIS), enter the computer name of the station in the [Computer name] field.
2. Click the [Add] button.
3. Click the [OK] button.
   The computer name of the station you entered is added to the tree view.

Deleting stations

1. Click one of the computer names displayed in the list in the Station Setup dialog box.
2. Click the [Delete] button.
3. Click the [OK] button.
   The selected station is deleted from the tree view.

I4.2.2 Setting Message Cache Service

Message Cache Service collects diagnostic information messages, SOE event messages and tripping information from the displayed SCS while the Diagnostic Information window or SOE View is running. If an SCS is set as the target of automatic data acquisition, data is automatically acquired regardless of the running of these windows.

The SCS to be the target of automatic acquisition and the maximum disk cache usage are set in the Setup dialog box.

Displaying the Setup dialog box

From the [File] menu of the Message Cache Tool window, select [Setup]. The Setup dialog box appears.

Setting items

The following describes the Items that should be set in the Setup dialog box.

- Target of automatic acquisition
  Specify an SCS to be the target of acquisition by Message Cache Service. Diagnostic information messages and SOE event messages of the SCS specified here are collected at the same time Message Cache Service starts up.
- Maximum Capacity of Disk
  The maximum message cache service size needs to be specified according to the actual usage. Up to the maximum disk capacity can be used for Message Cache Service.

IMPORTANT

Make sure that the disk used for DISK Cache by the Message Cache Service always has enough free space. (Default Max. Disk capacity: 800 MB) Monitoring for the Maximum Capacity is performed every 30 seconds. If the disk usage for the disk cache exceeds the Maximum Capacity, oldest files are deleted to keep the usage rate of the disk cache at 98 % to 100 %. For your information, 1 MB can contain about 8000 Diagnostic Information messages or 16000 events. The cache file is stored for each station. "SOE including Trip" and "Diagnostic Information messages" are stored separately in the cache file. If you want to keep the old cache files undeleted, save the files in a separate folder or media from the Save Disk Cache dialog box. To view the disk cache usage rate, use the Message Cache Tool: click [DISK Cache] in the tree view.

SEE ALSO

For more information about the details displayed in the disk cache usage status, refer to:

I4.2.4, “Displaying disk cache usage status” on page I4-45

For more information about Saving disk cache, refer to:

I4.2.6, “Saving disk cache” on page I4-49

I4.2.3 Displaying data acquisition status

Acquisition status of diagnostic information messages, SOE event messages and tripping information collected from an SCS by Message Cache Service are displayed.

How to display data acquisition status

To display the data acquisition status, click and expand [Data Acquisition] in the tree view on the left pane of the window, and then click the name of SCS. The acquisition status of data collected from the selected SCS by Message Cache Service is displayed in the client area on the right.

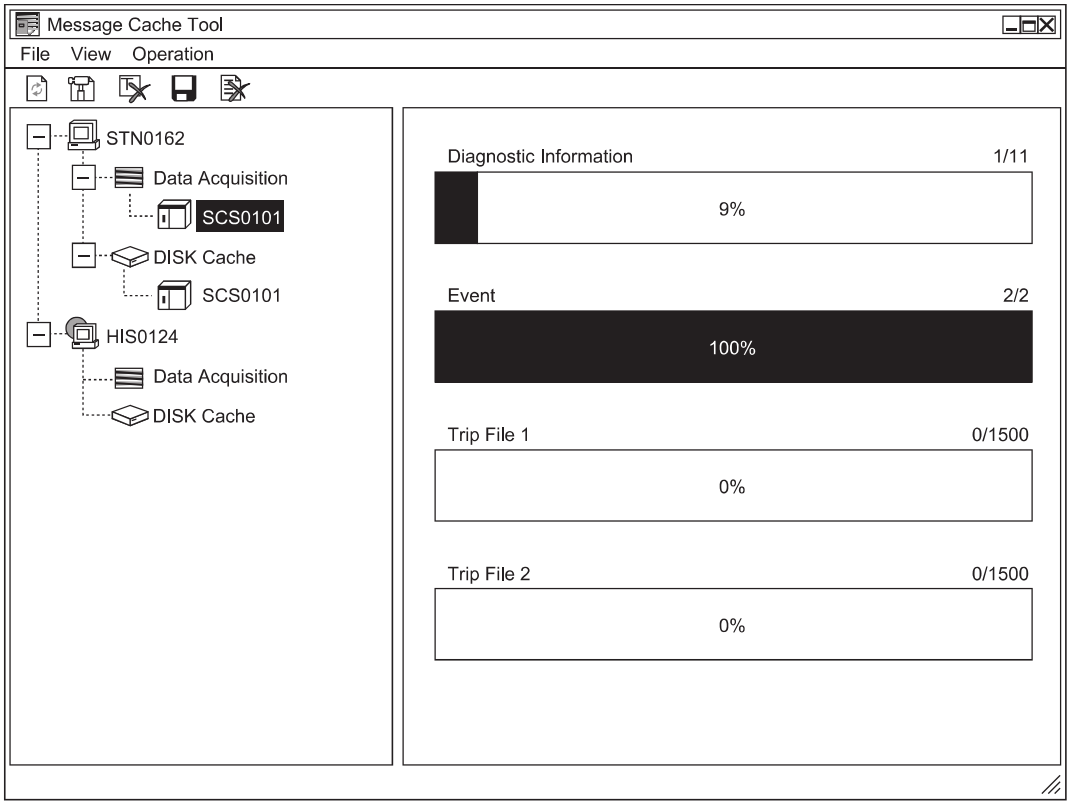

Figure I4.2.3-1 Data acquisition status

Items displayed for data acquisition status

The table below shows the items displayed for data acquisition status.

Table I4.2.3-1 Items displayed for data acquisition status

Displayed item	Description
Data Type	Displays the type of cache data (diagnostic information messages, SOE event messages and two types of tripping information).
Acquisition Status (Value)	Displays the number of items of diagnostic information messages, SOE event messages and tripping information acquired by Message Cache Service before "/", the diagnostic information messages, SOE event messages and tripping information that can be maintained by the SCS are displayed after the "/."
Acquisition Status (Bar Display)	Displays the percentage of data acquired by Message Cache Service with a bar. If no data is maintained by the SCS, "0%" is displayed on the bar. And, the bar is grayed out if data maintained by the cache service has not been updated for a certain period of time.

I4.2.4 Displaying disk cache usage status

With Message Cache Service, the cache data is stored on the hard disk until the data volume reaches the maximum disk cache usage set in the Setup dialog box. This function allows monitoring the disk cache (hard disk) usage status of Message Cache Service for all SCSs or each SCS managed by the station (SENG or HIS).

How to display disk cache usage status

The disk cache usage status is displayed using the following procedure for all or individual SCSs.

- Display for all SCSs
  Click [Disk Cache] in the tree view; the disk cache usage status for all SCSs managed by the station (SENG or HIS) is displayed.
- Display for each SCS
  Select the name of an SCS from the list of SCSs displayed by clicking [Disk Cache] in the tree view; the disk cache usage status for the selected SCS will be displayed.

Display for all SCSs

The disk cache usage status for the entire Message Cache Service running on each station (SENG or HIS) is displayed.

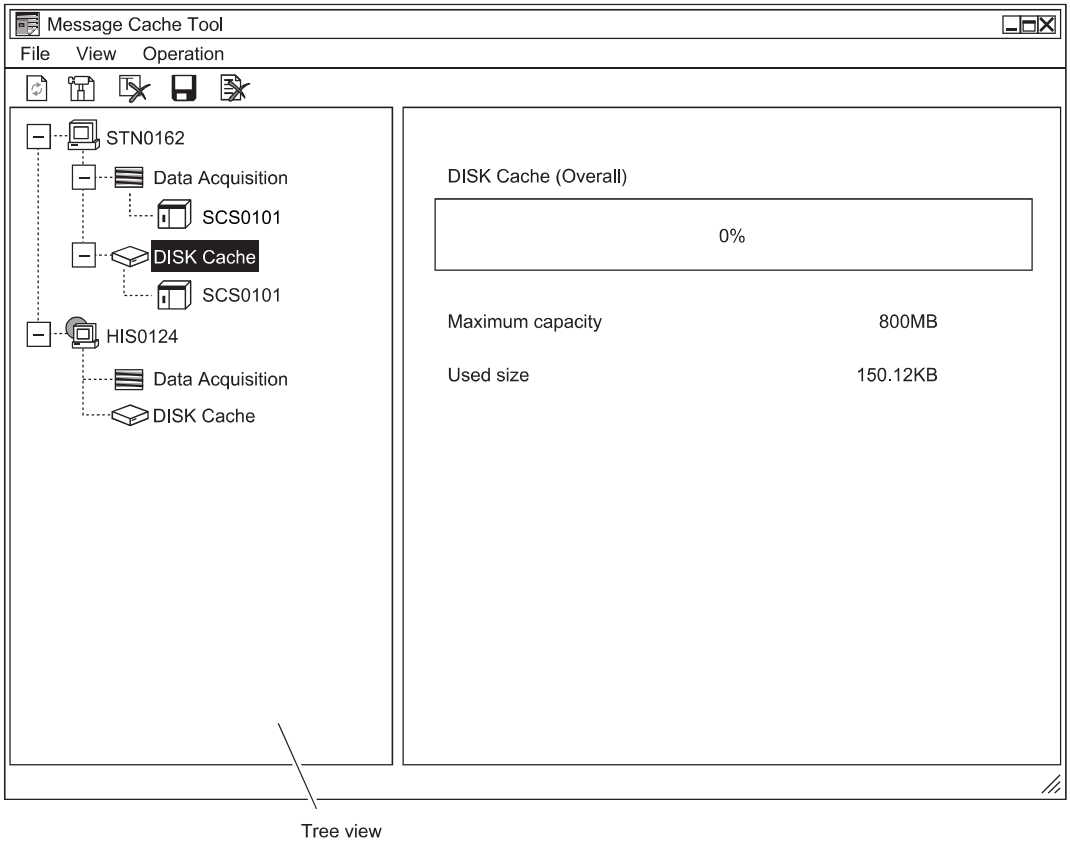

Figure I4.2.4-1 Disk cache usage status (display for all SCSs)

The table below shows the items displayed for the total disk cache usage status.

Table I4.2.4-1 Disk cache (display for all SCSs)

Displayed item	Description
Status of use (Bar Display)	Displays the percentage of the currently used disk space with a bar.
Maximum capacity	Displays the maximum disk space that can be used as disk cache. The maximum capacity is set in the Setup dialog box.
Used size	Displays the currently used disk cache space.

SEE ALSO For more information about the Setup dialog box, refer to:

I4.2.2, “Setting Message Cache Service” on page I4-43

Display for each SCS

The disk cache usage status for the selected SCS is displayed.

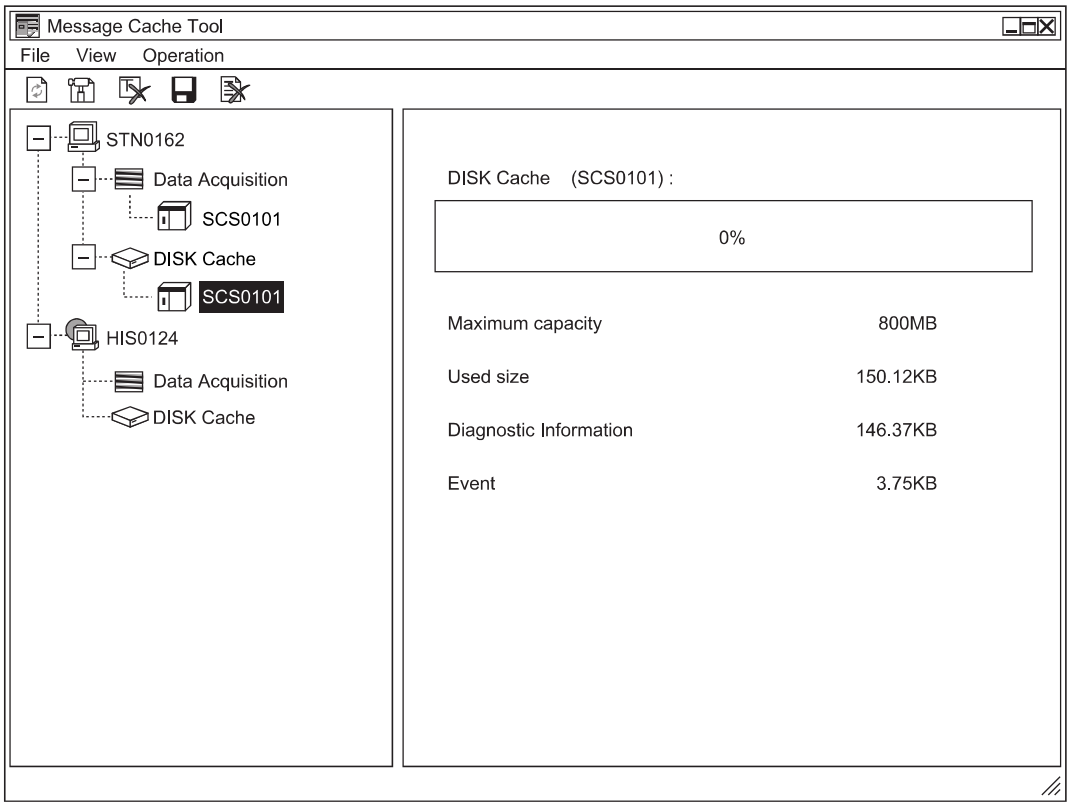

Figure I4.2.4-2 Disk Cache usage status (Display for each SCS)

The table below shows the items displayed for the each disk cache usage status.

Table I4.2.4-2 Disk cache (Display for each SCS)

Displayed item	Description
Status of use (Bar Display)	Displays the percentage of data acquired from the selected SCS out of the disk space with a bar.
Maximum capacity	Displays the maximum disk space that can be used as disk cache. The maximum capacity is set in the Setup dialog box.
Used size	Displays the volume of cache data acquired from the selected SCS.
Diagnostic Information	Displays the disk cache space used for diagnostic information messages.
Event	Displays the disk cache space used for SOE event messages.

SEE ALSO For more information about the Setup dialog box, refer to:

I4.2.2, “Setting Message Cache Service” on page I4-43

I4.2.5 Initialization of tripping information

Use the Initialize Trip Information dialog box to initialize the two types of tripping information held by the SCS.

After initialization, the SCS will get ready for collecting the tripping information in case the SCS trip occurs again.

Displaying the Initialize Trip Information dialog box

Select [Initialize Trip Information] from the [Operation] menu. The Initialize Trip Information dialog box appears.

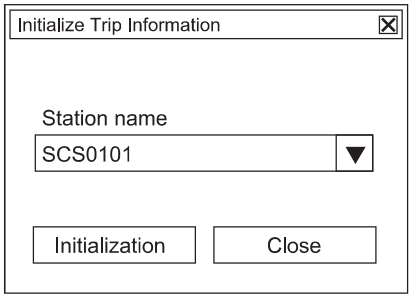

Figure I4.2.5-1 Initialize Trip Information dialog box

Initialize trip information operation

1. Select the SCS whose tripping information you want to initialize from the drop-down list box.
2. Click the [Initialization] button.
3. Click the [OK] button in the confirmation dialog box to initialize the tripping information.

IMPORTANT

When initializing the tripping information in a SCS, two files of SCS tripping information will be initialized together. Before initialization, make sure that the tripping information is saved in the SENG.

I4.2.6 Saving disk cache

Use this function to save the disk cache maintained in Message Cache Service to a separate folder or medium. The storage destination folder of the disk cache is specified by the Save Disk Cache dialog box. Saved disk cache can be viewed from SOE Viewer.

Displaying the Save DISK Cache dialog box

Select [Save Disk Cache] from the [Operation] menu. The Save DISK Cache dialog box appears.

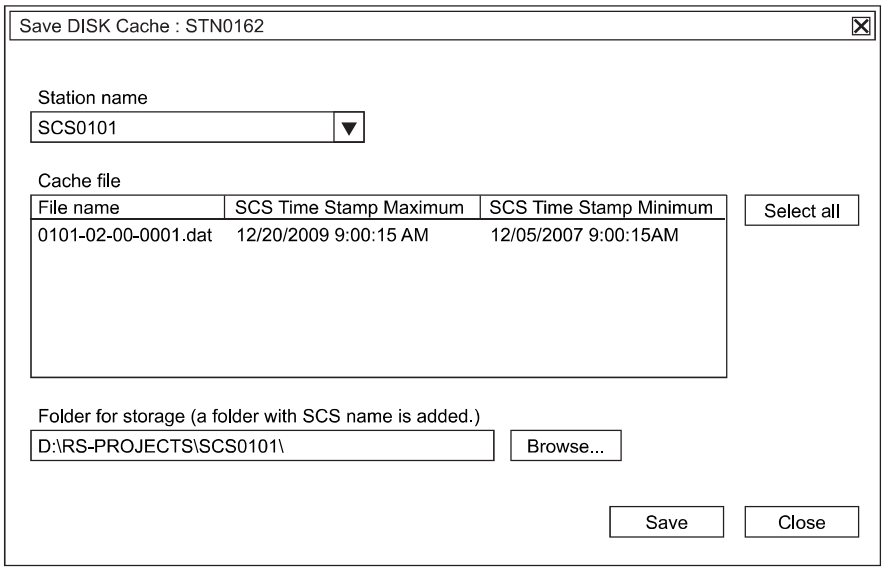

Figure I4.2.6-1 Save DISK Cache dialog box

How to specify the disk cache storage destination

1. Select a station name in the "Station name" field.
   Specify [All SCSs] in the "Station name" box to save the cache data of all SCSs.
2. Select the cache file to be saved from the "Cache file" field.
   Specify [Select All] to select all cache files of the specified SCS.
   If you have specified [All SCSs] in the "Station name" box , the cache files are grayed out.
3. Select a destination folder in which the disk cache is saved in the "Folder for storage" field. The folder with the selected SCS name is automatically created.
4. Click the [Save] button.
   The disk cache is saved in the specified folder.

SEE ALSO For more information about how to view the saved disk cache data, refer to:

"● Server Connection" on page I4-63

I4.3 SOE Viewer

On the SOE Viewer, events of ProSafe-RS can be analyzed. The event log in the specified SCS is uploaded to be displayed as event messages.

The SOE Viewer functions are as follows.

- The Event log (SOE event information and Diagnostic Information message) stored in SCS is uploaded to be displayed as event messages.
- Data sources of eight SCSs (including HIS for CENTUM Integration Structure) can be specified.
- Only event messages that you want to see can be filtered.
- A trip report can be generated. The report can be printed or exported as a CSV file.
- In case of CENTUM Integration Structure, process alarm messages from SCS can also be displayed.

The SOE Viewer has the following operation modes.

- Event Mode Operation
  It displays a list of event messages of SCS.

  In the case of CENTUM Integration Structure, HIS historical messages (process alarm messages of SCS) can also be displayed.
- Trip Mode Operation
  It displays a list of trip events of SCS. Detailed information about trip signals are also displayed.

I4.3.1 SOE Viewer window

The information managed by SOE Viewer is displayed in either the event mode or the trip mode. The window structure used in the event and trip modes is the same. This section explains the structure used for both modes.

Displaying SOE Viewer

Select [YOKOGAWA ProSafe] > [SOE Viewer].
SOE Viewer is displayed in the event mode.

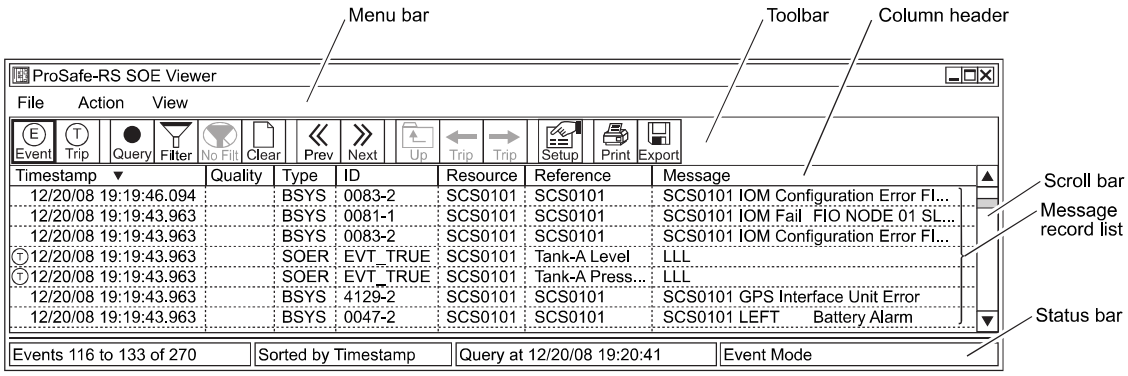

Figure I4.3.1-1 SOE Viewer (Event mode)

After starting the SOE Viewer, no event message is displayed in the message record list since no data source is specified. The event messages are displayed only after specifying the data source and running the query.

SEE ALSO For more information about setting the data source, refer to:

I4.3.2, “SOE Viewer configuration” on page I4-59

Menu bar

The menu bar provides the following menus.

- [File] menu
- [Action] menu
- [View] menu

Some of the commands in the menu bar are also provided in the toolbar. In addition to the commands available in the toolbar, the menu bar allows loading and saving property setting information (SOE Viewer configuration file) of SOE Viewer as well as setting the maximum number of message records.

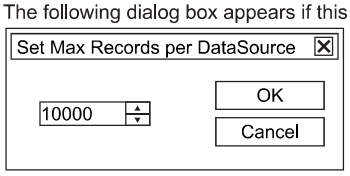
File menu

Table I4.3.1-1 File menu

Menu item	Description
Load Configuration	Loads the settings made in the SOE Viewer Properties dialog box, which was saved by Save Configuration
Save Configuration	Saves current settings (SOE Viewer configuration) made in the SOE Viewer Properties dialog box
Print	Prints all or selected records from the message record list
Export List to file	Exports all records from the message record list to a CSV format file

Continues on the next page

Table I4.3.1-1 File menu (Table continued)



Menu item	Description
Exit	Closes SOE Viewer

Action menu

Table I4.3.1-2 Action menu

Menu item	Description
Execute Query	Executes queries based on the current settings made in the SOE Viewer Properties dialog box because the message record list is not updated automatically
Clear List	Deletes the current message record list
Filter Results	Applies filtering set in the SOE Viewer Properties dialog box to the current message record list
No Filter/Remove Filter	Removes filter restrictions from the current message record list
Set Max Records	Sets the maximum number of message records that can be retrieved by a query from one data source. If this limit is exceeded, remaining records are discarded and a warning message is generated (the setting range is from 10 to 65535, the default value is 10000). (*1)

*1: The following dialog box appears if this menu item is selected.

View menu

Table I4.3.1-3 View menu

Menu item	Description
Event Mode	Changes the SOE Viewer display to the event mode
Trip Mode	Changes the SOE Viewer display to the trip mode
Prev Page	Scrolls the list to display records in the previous page
Next Page	Scrolls the list to display records in the next page
Go up one level	Returns the display to the trip mode from the trip detail display
Prev Trip	Displays trip detailed display of the previous trip trigger event
Next Trip	Displays trip detailed display of the next trip trigger event
Toolbar	Shows or hides the toolbar
Status Bar	Shows or hides the status bar
Warning/Error Log	Displays the Warning/Error Log dialog box of SOE Viewer
Properties	Displays the SOE Viewer Properties dialog box

Toolbar

The toolbar of SOE Viewer has the following buttons.

Table I4.3.1-4 Toolbar buttons

Button	Name	Button	Name
	[Event Mode] Button		[Next Page] Button
	[Trip Mode] Button		[Up to Trigger List] Button
	[Execute Query] Button		[Prev Trip Detail] Button
	[Filter data] Button		[Next Trip Detail] Button
	[Clear Filter] Button		[Properties] Button
	[Clear List] Button		[Print] Button
	[Prev Page] Button		[Export data] Button

Event Mode button

This button provides the same function as [Event Mode] in the [View] menu.

The [Event Mode] button switches the display of SOE Viewer to the event mode. SOE Viewer remains in the event mode until the [Trip Mode] button is clicked. The [Event Mode] button cancels the operation activated by clicking the [Trip Mode] button. In the event mode, if a query is made, messages are retrieved from up to eight data sources specified in advance.

SEE ALSO For more information about Event mode, refer to:

I4.3.3, “Event mode operation” on page I4-68

Trip Mode button

This button provides the same function as [Trip Mode] in the [View] menu.

The [Trip Mode] button switches the display of SOE Viewer to the trip mode. SOE Viewer remains in the trip mode until the [Event Mode] button is clicked. The [Trip Mode] button cancels the operation activated by clicking the [Event Mode] button. In the trip mode, if a query is made, trip trigger events are retrieved from the trip signal file of SCS and displayed.

SEE ALSO For more information about Trip mode, refer to:

I4.3.4, “Trip mode operation” on page I4-71

Execute Query button

This button provides the same function as [Execute Query] in the [Action] menu.

The [Execute Query] button uploads all event logs matching the date/time and data source parameters specified in the SOE Viewer Properties dialog box from an SCS. Event logs are filtered and displayed in the message record list of SOE Viewer as event messages.

If one or more data sources have been set, the [Execute Query] button can be used in both the event mode and the trip mode.

Filter Data button

This button provides the same function as [Filter Results] in the [Action] menu.

The [Filter data] button displays in the message record list only event messages matching the filter parameters specified in the SOE Viewer Properties dialog box. If the filtering is set anew or changed, it is applied to the result of the current query and the display is updated. The [Filter data] button is only enabled when there are event messages in the message record list.

- ### Clear Filter button

  This button provides the same function as [No Filter/Remove Filter] in the [Action] menu.

  The [Clear Filter] button displays all event logs uploaded from an SCS as the result of the previous query as event messages in the message record list. It is not necessary to perform a query anew. The [Clear Filter] button is only enabled when the display has been filtered.

- ### Clear List button

  This button provides the same function as [Clear List] in the [Action] menu.

  The [Clear List] button deletes the message record list. Generate a new query command to retrieve and display event messages from an SCS again.

  The [Clear List] button is only enabled when there are messages in the message record list.

- ### Prev Page button

  This button provides the same function as [Prev Page] in the [View] menu.

  The [Prev Page] button scrolls the display so that the records in the previous page of the message record list are shown.

- ### Next Page button

  This button provides the same function as [Next Page] in the [View] menu.

  The [Next Page] button scrolls to the records on the next page of the message record list.

- ### Up to Trigger List button

  This button provides the same function as [Go up one] level in the [View] menu.

  The [Up to Trigger List] button returns the display from the trip detail display to the trip mode. The [Up to Trigger List] button is active in the Trip Detail display only.

- ### Prev Trip Detail button

  This button provides the same function as [Prev Trip] in the [View] menu.

  The [Prev Trip Detail] button displays the previous trip trigger event generated in the trip detail display. The [Prev Trip Detail] button is active in the Trip Detail display only.

- ### Next Trip Detail button

  This button provides the same function as [Next Trip] in the [View] menu.

  The "Next Trip Detail" button displays the next trip trigger event generated in the trip detail display. The "Next Trip Detail" button is active in the Trip Detail display only.

- ### Properties button

  This button provides the same function as [Properties] in the [View] menu.

  The ["Properties] button displays the SOE Viewer Properties dialog box. This dialog box is used to configure properties for the operations of SOE Viewer.

SEE ALSO For more information about the SOE Viewer Properties dialog box, refer to:

I4.3.2, “SOE Viewer configuration” on page I4-59

Print button

This button provides the same function as [Print] in the [File] menu.

The [Print] button prints out event messages included in the message record list. The [Print] button is only enabled when there are messages in the message record list.

SEE ALSO For more information about Print button, refer to:

"■ Printing" on page I4-68

Export data button

This button provides the same function as [Export List to file] in the [File] menu.

The [Export data] button exports event messages included in the message record list, to a CSV format file. The [Export data] button is only enabled when there are messages in the message record list.

SEE ALSO For more information about Export button, refer to:

"■ Exporting" on page I4-69

Message record list

The message record list executes queries and displays event messages uploaded from an SCS in response to the queries. Each line represents one event message.

Message color

The messages of trip trigger events are colored so that they can easily be distinguished from other event messages. User can specify the colors in the SOE Viewer Properties dialog box.

Figure I4.3.1-2 SOE message color code

Table I4.3.1-5 SOE message colors

Record type	Background color	Icon	Text color
Trip Trigger	Yellow (default)	Yellow circle with black "T"	Black
All Others	White (Windows default color)	None	Black

SEE ALSO For more information about the SOE Viewer Properties dialog box, refer to:

I4.3.2, "SOE Viewer configuration" on page I4-59

Sorting messages

Messages can be sorted in ascending or descending order using the upward and downward arrows in the column header.

Figure I4.3.1-3 Sorting by timestamp (sorting in ascending order)

Figure I4.3.1-4 Sorting by timestamp (sorting in descending order)

Changing column width

If the width of a column or column header is too narrow to display the entire data and/or caption, as many characters as possible are displayed and the omitted characters are represented by an omission symbol (...).
The width of the columns can be changed by dragging the vertical boundary line between column headers.

Double-click the boundary line between column headers to adjust to the optimum width.

Changing display order of a column

To change the display order of a column, click the column header, keep the mouse button pressed and drag and drop it to the desired position.

TIP

The specified sorting order, column width and column order are saved in the SOE configuration file. These settings are restored when the SOE Viewer configuration file is uploaded using [Load Configuration] of the [File] menu.

Status bar

Figure I4.3.1-5 Status bar

The status bar is displayed at the bottom of the window. The status bar has four frames that display information related to the currently displayed message record list. The user can change the display width of the frames.

The information shown in each frame is explained as follows, starting from the leftmost frame.

- The total number of messages uploaded by a query from an SCS and the range of messages currently displayed
  If one or more filters are applied to the event messages displayed in the message record list, [F] is added at the end of the first status bar frame.

  For example, if a filter restricts the records to be displayed to 424 messages and each page displays 6 messages, the first frame of the status bar shows "Events 1 to 6 of 424 [F]."
- The column name currently used as the sorting key
- Date and time when the query was executed
- Display mode
  There are two display modes: fixed messages and temporary messages.

  The fixed messages indicate the current operating mode.

Table I4.3.1-6 Fixed messages

Message	Description
Event Mode	Indicates that SOE Viewer is in the event mode.
Trip Trigger Mode	Indicates that SOE Viewer is in the trip mode.
Trip Detail [Reference]	Indicates that SOE Viewer displays trip details. Reference information related to the current trip trigger event is also displayed.

The temporary messages indicate the current status during execution of a query.

Table I4.3.1-7 Temporary messages

Message	Description
Processing Query..	A query to a data source is being executed and SOE Viewer is waiting for the query result.
Loading Data..	Results of a query have been received and the Viewer is loading the messages into the dedicated memory.
Filtering Data..	The Viewer is filtering messages for display.

If a warning or error condition is generated during the operation of SOE Viewer, an exclamation mark icon is displayed in the display mode frame of the status bar.

Double-click the exclamation icon; the Warning/Error Log dialog box appears and displays warning and error message information. Click a message displayed in the Warning/Error Log dialog box to see the detailed information.

Figure I4.3.1-6 Exclamation icon

SEE ALSO For more information about warnings and error messages, refer to:

I4.3.5, “Troubleshooting SOE Viewer” on page I4-73

Event Detail dialog box

The Event Detail dialog box displays detailed information about event messages selected in the message record list. To display the Event Detail dialog box for messages displayed in the event mode or the Trip Detail Display window, double-click an event message or press the [Enter] key on the keyboard in the message record list.

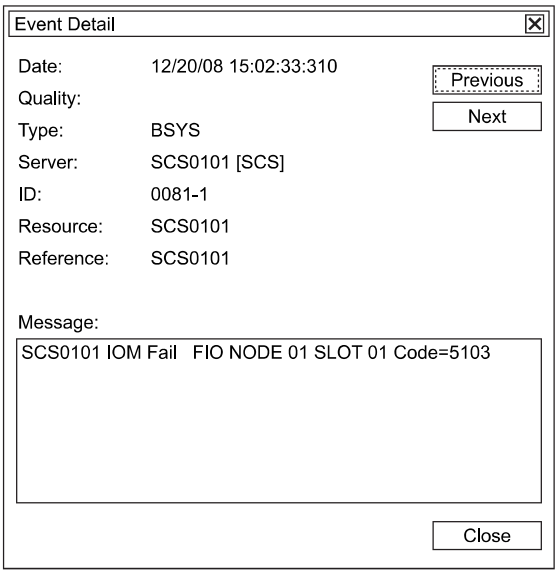


Figure I4.3.1-7 Event Detail dialog box

The information of data sources displayed in the Event Detail dialog box is summarized as follows.

Table I4.3.1-8 Event detail items

Event detail items	Description	SOE event information				Diagnostic information	HIS historical information
		DI	DO	AI	Internal variable		
Date (*1)	Date and time when a message is generated. The date format is specified in the SOE Viewer Properties dialog box. The time is displayed using the format hh:mm:ss:ttt where: hh = hours (24 hours), mm = minutes, ss = seconds and ttt = ms.	Time at which the SOE event information was generated in the SCS				Time at which the alarm is generated in an SCS	Time at which the alarm is generated in an SCS
Quality	Time synchronization information when an event occurs	I, B, V, <Blank> (*2)	-			-	-
Type	Message type	SOER (SOE event information)				BSYS (diagnostic information message)	Message category (Example: BSYS, BPRO) (*3)
Server [Type]	Name and type of the server that output a message	SCSddss [SCS](*4)				SCSddss [SCS] (*4)	HIS computer name [HIS]
ID	Message identifier	EVT_TRUE EVT_FALSE				Message ID-alarm class (e.g., 0047-2)	Message ID-alarm class or alarm priority (e.g., 1101-1)
Resource	Message reference station name	Station name (SCSddss) (*4)					
Reference	Special reference point of message	Comment entered for the input/output variable		Any character string assigned to a function block		Station name	Station name, tag name
Message	Message itself	Data value, numerical value (TRUE, FALSE)		Data value, character string (e.g., HTRP)	Data value, numerical value, BOOL, DINT, REAL	Message character string	Message character string

*1: "Timestamp" is displayed in the SOE Viewer window either in event mode or trip mode.
*2: The status of time synchronization on DI event generation is indicated with the following characters.
I: Not synchronized with the standard time.
B: Synchronized with the standard time but synchronization signals are not provided for some reason.
V: Not synchronized with the time on the SNTP server.
<Blank>: Synchronized with the IRIG-B signal when connected to an IRIG-B. Synchronized with the time on the SNTP server when an SNTP server is used on Vnet/IP.
*3: BSYS indicates a system alarm message and BPRO indicates a process alarm message.
*4: In SCSddss, dd indicates the domain number and ss indicates the station number.

To see event details of the previous message in the message record list, click the [Previous] button or press the [P] key on the keyboard. To see event details of the next message in the message record list, click the [Next] or press the [N] key on the keyboard. Click the [Close] button to close the Event Detail dialog box.

I4.3.2 SOE Viewer configuration

The data source settings for SOE Viewer is made in the SOE Viewer Properties dialog box. This section explains the operations performed in the SOE Viewer Properties dialog box: specifying of data sources and date ranges, filtering standards to be applied and general settings for SOE Viewer.

How to display the SOE Viewer Properties dialog box

Click [Properties] button in the toolbar or select [Properties] in the [View] menu; the SOE Viewer Properties dialog box appears.

General tab

The following items are specified in the "General" tab.

- Display or hide the Toolbar
- Select the toolbar icons to use small or large
- Display or hide the Status Bar
- Choose the SOE message color settings
- Display/suppress the Warning/Error Log dialog box

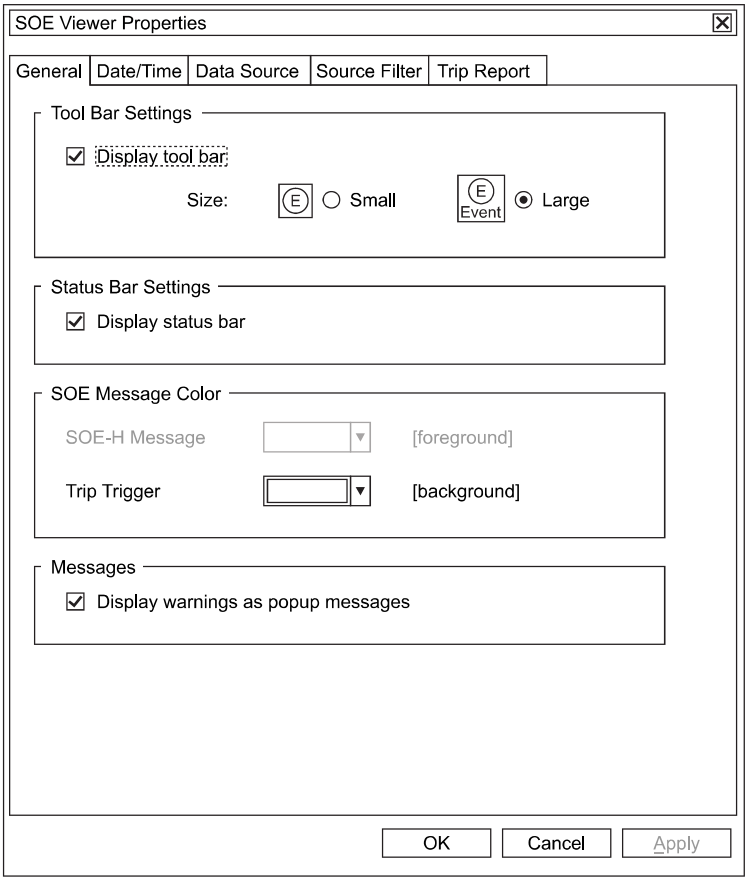

Figure I4.3.2-1 General tab of SOE Viewer Properties dialog box

Tool bar settings

To display the toolbar, select the [Display tool bar] check box. To display only tool buttons on the toolbar, select the [Small] radio button for "Size." To display tool buttons along with an identifying caption, select the [Large] radio button for "Size."

Figure I4.3.2-2 Small button

Figure I4.3.2-3 Large button

● Status bar settings

To display the status bar, check the [Display status bar] check box.

● SOE message color

Select the background color of trip trigger events in this section. Click the downward arrow to display the color picker. Use the color picker to select the desired color. The default background color for trip trigger events is yellow.

Figure I4.3.2-4 Color picker

● Messages

Select the [Display warnings as popup messages] check box to notify about query warnings via an interactive pop-up dialog box. If this check box is not selected, it becomes necessary to display the Warning/Error Log dialog box to view query warnings.

■ Date/Time tab

The "Date/Time" tab is used to specify the range of date and time of messages uploaded from an SCS by the query in the event mode or the trip mode. The date/time format is also specified in this tab.

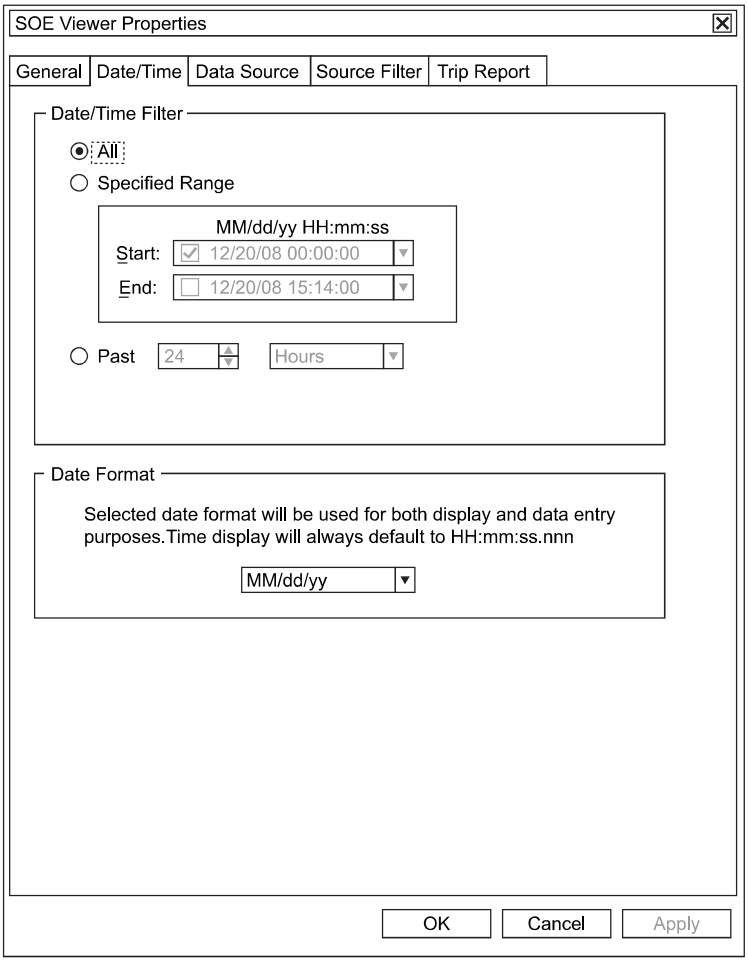

Figure I4.3.2-5 Date/Time tab of the SOE Viewer Properties dialog box

Date/Time Filter

The date/time filter can be specified in the following manners:

- [ALL]
- No date range is specified. All event messages that have occurred within the past one year are displayed as a result of query for each data source. Note that the number of event messages displayed is limited by the maximum number of records. When the number of total messages exceeds the maximum number of records for display, the latest messages cannot be displayed. In this case, a criterion with specified dates should be used for displaying the messages. Select [Specified Range] or [Past] if you want to display messages that have occurred within a specific period.
- [Specified Range]
  A specific date/time range is specified as the target period of queries. This range can be specified by the start date/time or the end date/time, or both. To include a start or end date/time in the definition of the specific range, select the relevant check box. If the start date/time is not specified, the date/time of the oldest event saved in an SCS is set as the start date/time. If the end date/time is not specified, the date/time of the most recently generated event message is set as the end date/time.

  To change the start or end date, enter a new date or click the downward arrow on the right side of date/time; a calendar appears. The current date is highlighted in red. Click the desired date.

To change the start time or end time, enter the time using 24-hour format.

Figure I4.3.2-6 Calendar

TIP

The values of currently selected date/time unit (i.e., hours or minutes) can be increased or decreased by pressing the [+] or [-] key on the keyboard.

- [Past]
  A range of messages generated in the past is specified as the target period of queries as the time span of hours or days. The time span is specified in units of minutes, hours, or days. If 0 days are specified, events and alarms generated at 0:00 a.m. of the current day and onward are uploaded from the SCS in question. If a number of days is specified, the target hours start from 0:00 of the day. For example, if 1 day is specified, the target hours start from 0:00 a.m. the day before.

Date Format

All dates within SOE Viewer are displayed using the date format specified here. Select a desired date format from the pop-up list. The following formats are available.
MM/dd/yy, dd/MM/yyyy, MM/dd/yyyy,

d-MMM-yy, dd/MM/yy, d-MMM-yyyy

Example 1: 30/10/2009

Example 2: 30-OCT-2009

TIP

If the message record list or the Event Detail dialog box is being displayed, the setting of the date format is reflected the next time a query is executed.

Data Source tabs

Eight "Data Source" tabs are prepared for the data sources; they are used to specify the data source and type of event messages.

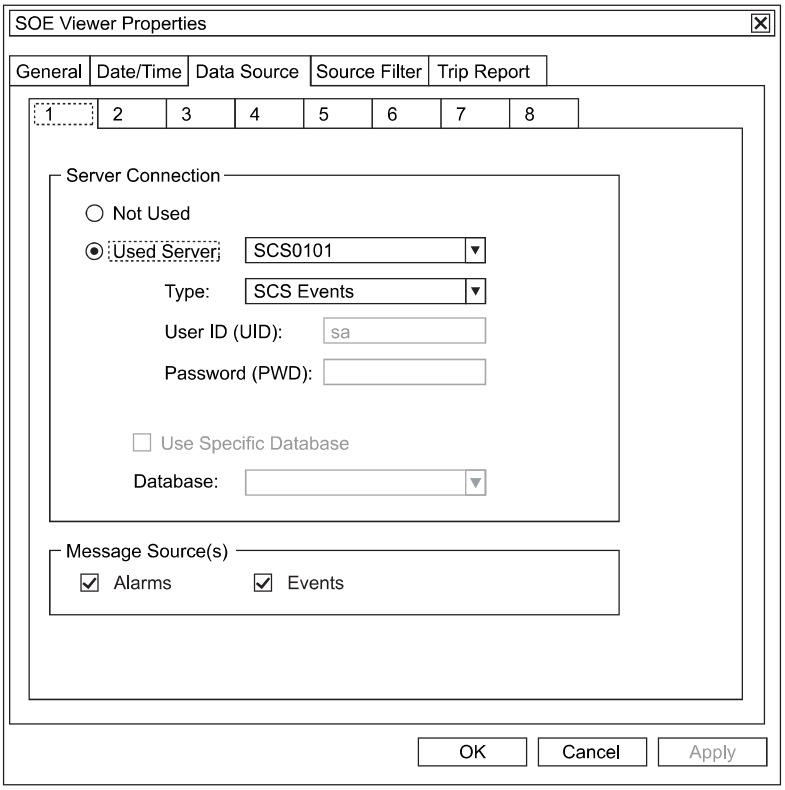

Figure I4.3.2-7 Data Source tab of SOE Viewer Properties dialog box

TIP To disable a server temporarily, select [Not Used]. Other settings made for the server are not deleted.

Server Connection

A data source is specified by entering a station name of an SCS. When the user executes a query, event logs are uploaded from the specified SCS and displayed in the event mode in SOE Viewer as event messages. To specify a data source, select [Used Server].

In the case of a CENTUM integration structure, HIS historical information (process alarms of an SCS) can also be specified as the data source. To do so, enter the computer name of HIS into the [Used Server] field. If you want to view the cached data saved using the Message Cache Tool, enter into the [Used Server] field the full path to the folder where the cash data is stored.

The setting items for Server Connection are shown in the table as follows.

Table I4.3.2-1 Server Connection setting items

Setting item	SCS event message	HIS historical information
Used Server	SCSddss (*1) or full path to the folder where the cash data is stored	HIS computer name
Type	SCS Events	CENTUM HIS Log

*1: Specify a domain number for dd and a station number for ss in SCSddss.

If the data source is not used, select [Not Used] to avoid a generation of error messages.

Message Source(s)

Specify the type of event messages retrieved from an SCS by a query.
If the [Alarms] check box is selected, diagnostic information messages are the target of collection. If the [Events] check box is selected, SOE event information are the target of collection. Select either the [Alarms] or [Events] check box, or both. Both check boxes are selected by default.

Source Filter tab

If a query is executed with the date range specified in the "Date/Time" tab while one or more filter parameters are specified, the filter is applied to event messages displayed in the message record list. Filter parameters can be specified for each data source. These filter parameters are automatically applied to the current query result. It is not necessary to execute a query anew in SOE Viewer even if filter parameters are changed.

Server Connection

This section displays the server name and the type of data source related to the filter specified in this tab. These fields are grayed out and cannot be changed.

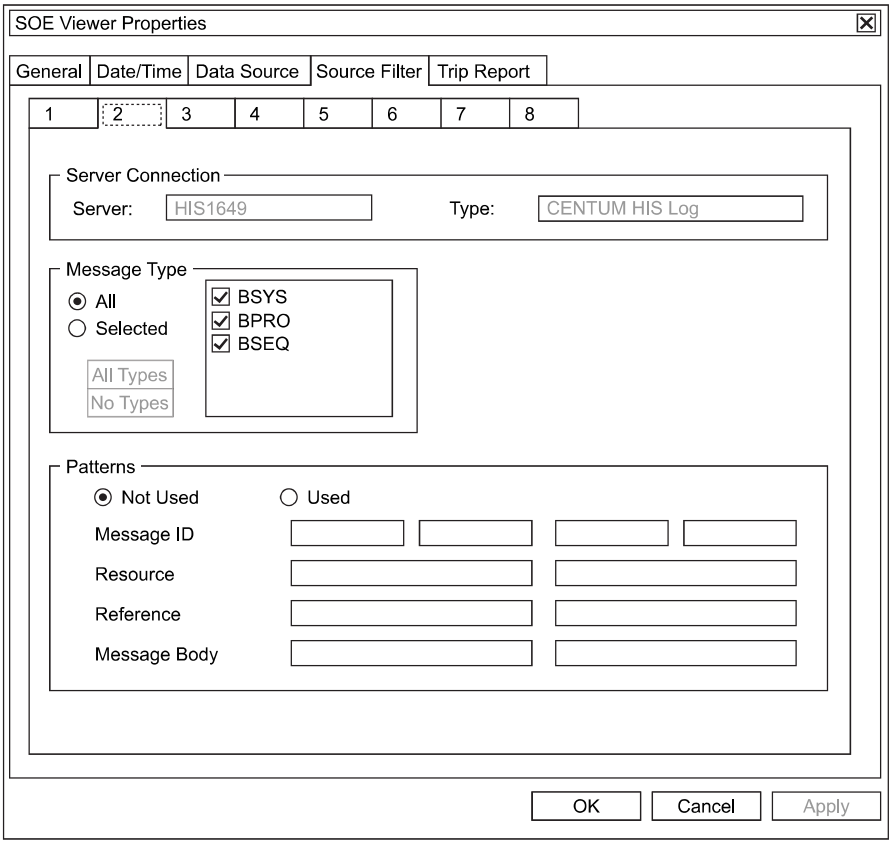

Figure I4.3.2-8 Source Filter tab of SOE Viewer Properties dialog box (example when Server Type is CENTUM HIS log)

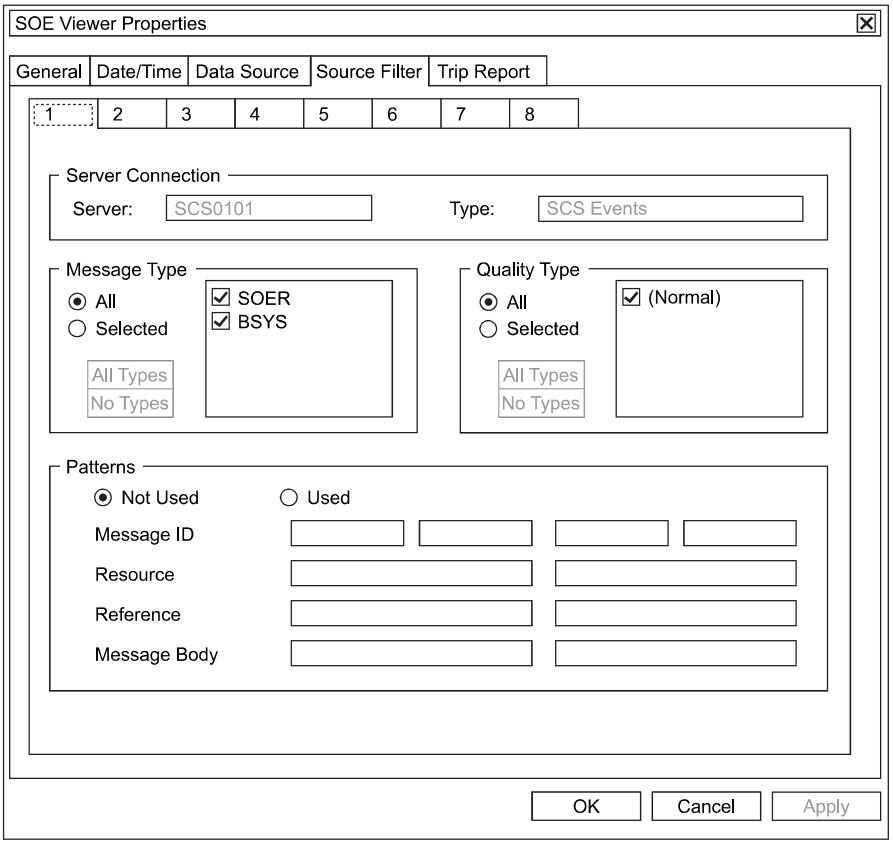

Figure I4.3.2-9 Source Filter tab of SOE Viewer Properties dialog box (example when Server Type is SCS events)

Message Type

It is possible to select the messages displayed in SOE Viewer according to the specific message types. The lists of event messages to which the message type selections are applied are automatically executed from the data source during a query.

- [All]
  Select all message types without restrictions.
- [Selected]
  Restrict the display to only the specified message type. Check the check box of the desired type.

  [All Types]: Select all message types at once.

  [No Types]: Deselect all message types at once.

Quality Type

This filter is only valid when the server type is SCS Events.

It is possible to select the event messages displayed according to the quality of the attached time stamp information.

- [All]
  Select all quality types without restriction.
- [Selected]
  Restrict the display to only the specified quality type. Check the check box of the desired type.

  [All Types]: Select all quality types at once.

  [No Types]: Deselect all quality types at once.

Patterns

It is possible to select the event messages displayed to those including the character string pattern specified in the relevant field.

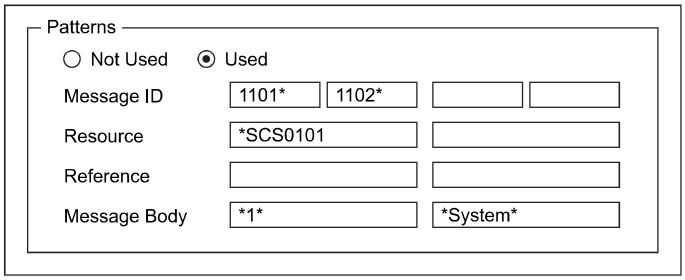

Figure I4.3.2-10 Source Filter tab (Patterns)

- [Not Used]
  No selections related to character string patterns are applied.
- [Used]
  Selections related to character string patterns are applied. Specify the desired patterns to be matched.

It is possible to use wildcards of asterisks (*) and question marks (?) in the character string patterns. "*" placed in front of a character string indicates any number of arbitrary characters before the character string. If an asterisk is placed after a character string, the wildcard indicates any number of characters after the character string. "?" is a wildcard indicating one arbitrary character.

If multiple character string patterns are specified for one pattern type (e.g., multiple character string patterns are specified for Message ID only), the filtering result includes all messages matching any of the specified patterns (patterns are combined using OR condition).

If two or more pattern types are specified (e.g., a character string pattern is specified for Message ID and Resource), the result includes only messages that match all of the specified patterns (patterns are combined using AND condition).

In the pattern example shown in the previous figure, all messages satisfying the following conditions are displayed:

Message(s) "whose message ID starts with 1101 or 1102" and "whose resource name ends with SCS0101" and "whose message text includes ‘1’ or ‘System’ somewhere in the message."

TIP Specified filter patterns are not deleted by selecting [Not Used] in order to avoid re-entering conditions from scratch in case the specified filter patterns may be needed again. If the patterns are needed again, change the option to [Used].

Trip Report tab

The "Trip Report" tab is used to specify the trip source. It is only valid when the server type is SCS Events. To display messages in the trip mode in SOE Viewer, specify the trip source in the "Trip Report" tab and execute a query.

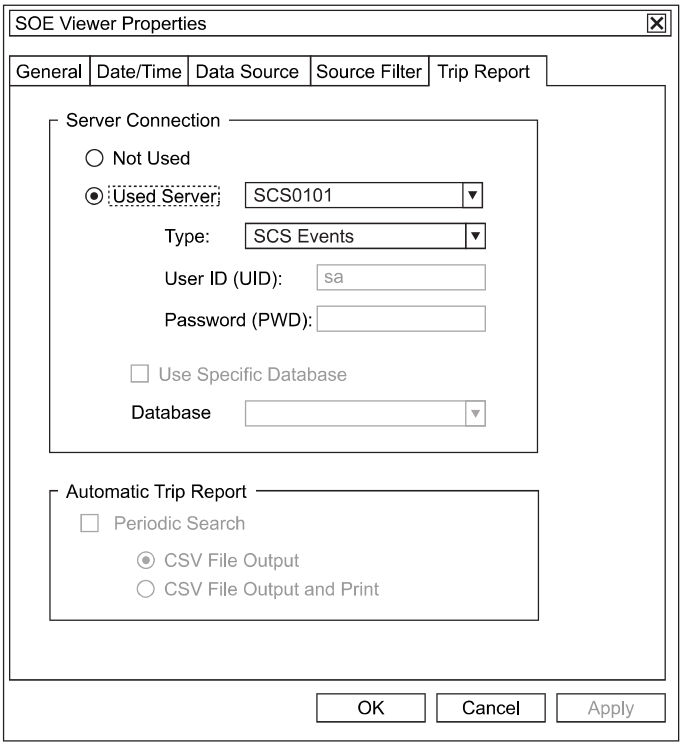

Figure I4.3.2-11 Trip Report tab of the SOE Viewer Properties dialog box

Server Connection

Specify the destination of the trip source. To specify a trip source, select [Used Server]. Specify SCSddss (dd: domain number, ss: station number) for the server name. Select [SCS Events] from the drop-down list of [Type].

Saving settings

Click the [OK] button to save the changes to settings made in the SOE Viewer Properties dialog box and close the dialog box.
Click the [Cancel] button to close the dialog box without saving the changes.

To retain the configured property settings for use in future SOE View sessions, select [Save Configuration] in the [File] menu.

I4.3.3 Event mode operation

In this mode, SOE Viewer displays event messages of an SCS in a list format. This allows analyzing events from relevant information using filtering. This section explains typical operations in the event mode of SOE Viewer.

Activating the Event mode

When you start SOE Viewer, the event mode is automatically activated. When you start up SOE Viewer for the first time, no data source is setup. Specify one or more data sources in the SOE Viewer Properties dialog box.
Properties can be set by reading an SOE Viewer configuration file set and saved in advance. If an SOE Viewer configuration file is read, the name of the file is displayed in the title bar of SOE Viewer.

If it is desired to change the display to the event mode while SOE Viewer is in the trip mode, click [Event Mode] button on the toolbar. Alternatively, select [Event Mode] in the [View] menu. SOE Viewer switches to the event mode.

Data source query

If a query is executed, event messages matching the date/time and the data source parameters specified in the SOE Viewer Properties dialog box are acquired, up to the maximum number of records. The event messages are displayed in the message record list of SOE Viewer. In order to execute a query, click [Execute Query] button on the toolbar. Alternatively, select [Execute Query] in the [Action] menu.

Message filtering

The filtering function is used to select only messages of interest among the displayed messages. Filtering by data source is performed based on the message type, message status and filtering pattern settings in the "Source Filter" tab of the SOE Viewer Properties dialog box. It is possible to set different filtering settings for each data source.
In order to apply filtering, click [Filter data] button on the toolbar. Alternatively, select [Filter Results] in the [Action] menu. The results of the current query are filtered automatically; it is not necessary to execute a query anew.

To view all messages without applying filtering, click [Clear Filter] button on the toolbar. Alternatively, select [No Filter/Remove Filter] in the [Action] menu.

Printing

It is possible to print messages displayed in the message record list. Select [Print] button on the toolbar or [Print] in the [File] menu. The standard Windows print dialog box appears.
The orders of columns and sorting used for the printout match with the display in SOE Viewer. The following example shows a printout from SOE Viewer.

Query at 12/20/08 13:51:42 SOE Viewer Report Page1

Timestamp	Quality	Type	ID	Resource	Reference	Message
12/20/08 14:52:27.740		BSYS	4125-1	SCS0101	SCS0101	SCS0101 IOM Channel Error ...
*12/20/08 14:52:27.740		SOER	EVT_TRUE	SCS0101	Tank-A Level	LLL
*12/20/08 14:52:27.740		SOER	EVT_TRUE	SCS0101	Tank-A Pressure	LLL
12/20/08 14:52:43.244		BSYS	4180-4	SCS0101	SCS0101	SCS0101 Security Level=1 ...
12/20/08 14:52:44.644		BSYS	4173-4	SCS0101	SCS0101	SCS0101 Writing Security Pa ...
12/20/08 14:52:48.744		BSYS	4180-4	SCS0101	SCS0101	SCS0101 Security Level=0 ...

All Messages from [Begin] to [END]

Figure I4.3.3-1 Example of printout

TIP "*" (asterisk) in the Timestamp column indicates a trip trigger event.

A footer is combined from the following character strings according to the messages printed, and then attached to the printed pages.

"All" or "Selected" or "Filtered" + "Messages from" + "StartDate" to "EndDate"

Either one of the "All," "Selected" or "Filtered" is printed out.

- All
  Indicates that all event messages in the printing range are specified.
- Selected
  Indicates that only event messages selected in the printing range are specified.
- Filtered
  Indicates that event messages are filtered.
- StartDate
  Indicates the start date/time of a query request.
  [Begin] means that no specific start date is specified.
- EndDate
  Indicates the end date/time of a query request.
  [End] means that no specific end date is specified.

Exporting

It is possible to export data displayed in the message record list to a CSV format file. It is also possible to specify whether or not to apply filtering when exporting the data.
Select the [Export data] button on the toolbar or [Export List to file] in the [File] menu.

The Export SOE Viewer data dialog box appears. Specify the name and location of a file and click [Save].

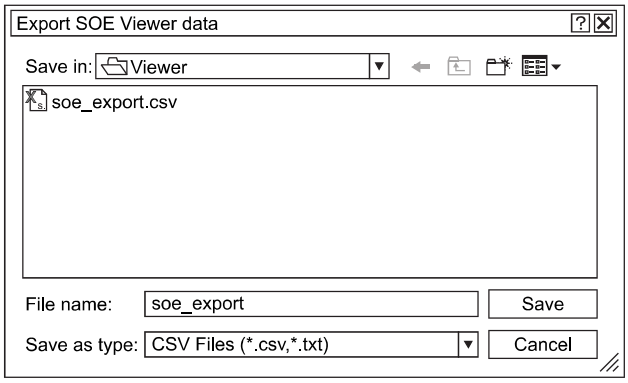

Figure I4.3.3-2 Export SOE Viewer Data dialog box

The first line of a CSV file describes the output column format. The order of columns of an exported file is always the same, even if the column order has been changed in SOE Viewer. The header line is as follows.

Timestamp, Quality, Type, ID, Alarm State, Resource, Reference, Message

```
Timestamp,Quality,Type,ID,Alarm State,Resource,Reference,Message
 *12/05/07    15:02:33.310,,SOER,EVT_TRUE,,SCS0101,Tank-A Level,LLL

Figure I4.3.3-3 Example of CSV file

TIP

"*" (asterisk) in the Timestamp column indicates a trip trigger event.

I4.3.4 Trip mode operation

In this mode, SOE Viewer displays only trip trigger events specified as trip signals in a list format. It also displays detailed information generated near a specified trip trigger event for analysis. This section provides an overview of the trip mode of SOE Viewer and information displayed in the trip detail display.

Activating the Trip mode

Click [Trip Mode] button on the toolbar or select [Trip Mode] in the [View] menu. SOE Viewer switches to the trip mode.
The trip trigger event list is blank until a query is executed. Once a query is executed, trip signals in the specified date range are uploaded from the specified data source and the trip trigger events are displayed in the trip trigger event list. This data is displayed again when the trip mode is activated again.

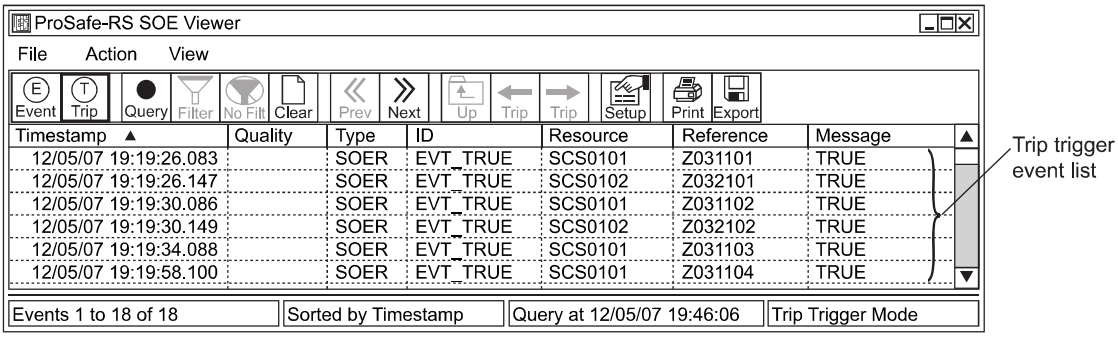

Figure I4.3.4-1 SOE Viewer (Trip mode)

Trip detail display

The Trip Detail Display window displays detailed trip records related to the trip trigger event selected in the trip mode of SOE Viewer. If you double-click a trip trigger event in the trip mode or press the [Enter] key on the keyboard, a query is automatically executed for the specified data source. The time range to be displayed in the Trip Detail Display window is determined based on the selected trip trigger event and approximately 500 events and 1000 events before and after the selected trip trigger event, respectively, and all the events generated in the time range, including other SCS events, are displayed as detailed trip records.

The initial display of the trip detail record list is a page that includes the selected trip trigger event.

The display mode frame of the status bar shows Trip Detail followed by the Reference information related to the current trip trigger event.

In the Trip Detail Display window, the [Up to Trigger List], [Prev Trip Detail] and [Next Trip Detail] buttons are enabled on the toolbar.

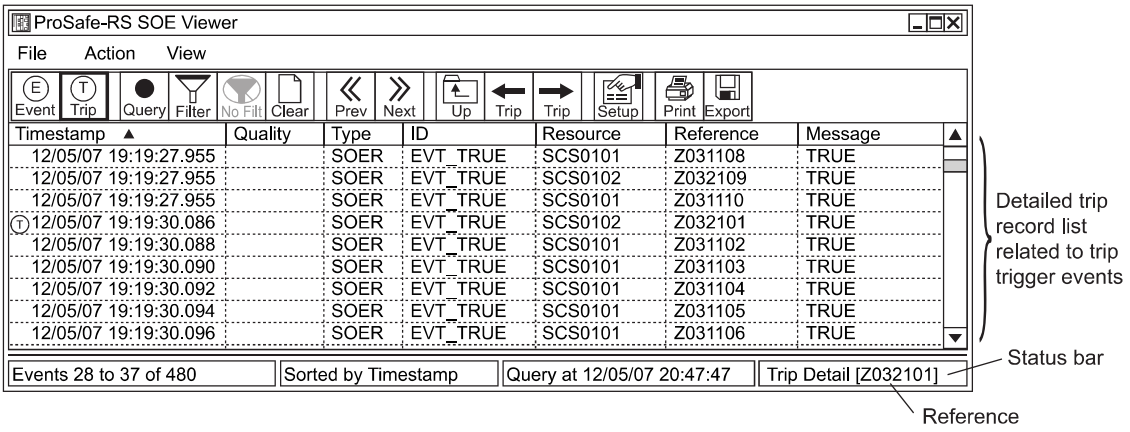

Figure I4.3.4-2 Trip Detail Display window

I4.3.5 Troubleshooting SOE Viewer

SOE Viewer displays warnings and error messages in the Warning/Error Log dialog box. Errors occur in file input/output or database access operations. This section explains how warnings and error messages are displayed and the actions to be taken.

Notification via the Warning/Error Log dialog box

If a warning or error condition occurs during operation of SOE Viewer, an exclamation icon is displayed in the display mode field of the status bar at the bottom of the SOE Viewer window. If you double-click the icon, the Warning/Error Log dialog box appears. This dialog box also appears by selecting [Warning/Error Log] in the [View] menu.

Click a message in the Log column of the Warning/Error Log dialog box to view detailed information about the message in the [Detail] area. Up to 1000 warning/error messages can be displayed. If more than 1000 messages have been recorded, messages are deleted starting from the oldest message.

Figure I4.3.5-1 Exclamation icon

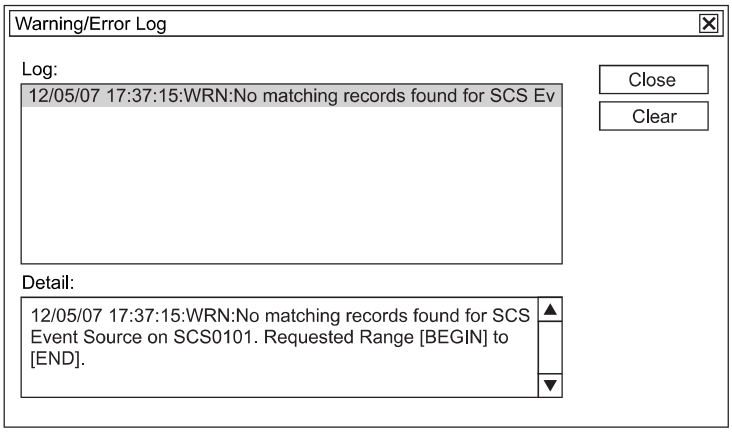

Figure I4.3.5-2 Warning/Error Log dialog box

Click the [Clear] button to delete all messages displayed in the Warning/Error Log dialog box. Click the [Close] button to close the dialog box.

The tables below show error messages and warning messages that may be generated.

Table I4.3.5-1 Error messages

Message	Explanation	Action
Error loading configuration file [Filename]	Uploading the specified SOE Viewer configuration file failed.	Check that the specified file name and path name are correct and perform the upload operation again.
Error on file [Filename] Cause: An attempt was made to access Event past its end.	Uploading the specified SOE Viewer configuration file failed. The file was found but the data or format of the file is illegal.	Upload settings from a normal SOE Viewer configuration file or use the SOE Viewer Properties dialog box to make the settings manually.

Continues on the next page

Table I4.3.5-1 Error messages (Table continued)

Message	Explanation	Action
Unable to connect to HIS server: [ServerName] Error 0x20000116 on HIS OpenLog( )	SOE Viewer failed to make a query for messages from the specified HIS server. An HIS log file cannot be opened.	Check that the specified server name and path name are correct. Check that network communication between the HIS server and SOE Viewer PC is functioning correctly. Check also that there is at least one "Daily Hishist log" file in the HIS corresponding to the requested date range.
Could not obtain Cache Data.	Cache data could not be acquired.	The message cache service is not running and/or in the process of starting up. Wait for a while and try again.
SOE viewer package of ProSafe-RS not installed.	The ProSafe-RS package has not been installed.	The problem may be solved by re-installing the ProSafe-RS package. If the error persists even if the package is re-installed, contact the service department.
Could not obtain V net address. Check [Used Server:].	Network address of the control bus could not be acquired.	Check that the correct server name is entered in the [Used Server] field.
librhhmscache.dll is damaged.	A program file is damaged.	The problem may be solved by re-installing the ProSafe-RS package. If the error persists even if the package is re-installed, contact the service department.

Table I4.3.5-2 Warning messages

Message	Explanation	Action
No matching records found for [SCS/HIS] Event Source on [ServerName]	No record was found in the date range requested in the specified server.	This occurs under normal circumstances as well. Expand the date range of messages on which queries are performed as necessary.
Results from [SCS/HIS] Event Source on [ServerName] exceeded limit.	The number of records in the date range requested for the specified server exceeded the specified limit. Records outside the range are discarded.	Make the requested date range of messages smaller or make the maximum number of records (MaxRecordsPerSource) as large as possible.
Input a correct SCS name into [Used Server:]. (For example, SCS0101) (*1)	The format of the entered SCS name is illegal.	Enter the correct SCS name. The correct SCS name format is SCSddss (dd: domain number, ss: station number).

*1: Warnings are notified via pop-up dialog boxes even if the [Display warnings as popup messages] check box is disabled.

Notification in the Error dialog box and the Warning dialog box

If an error or warning is generated, a pop-up dialog box appears to notify about the error message or warning message at the time of occurrence.

Messages displayed in the Error and Warning dialog boxes can also be viewed in a list in the Warning/Error Log dialog box.

Error message display

Errors generated during operation of SOE Viewer are notified via the Error pop-up dialog box. If an error occurs while executing a query, the user can cancel the query request or retry the query for the next specified data source.

Figure I4.3.5-3 Error dialog box

Click the [Retry] button to retry the query for the next specified data source and click the [Cancel] button to cancel the query request.

Warning message display

Warnings generated while executing a query for a data source are also notified via the Warning pop-up dialog box. The Warning dialog box appears if you select the [Display warnings as popup messages] check box in the "General" tab of the SOE Viewer Properties dialog box.

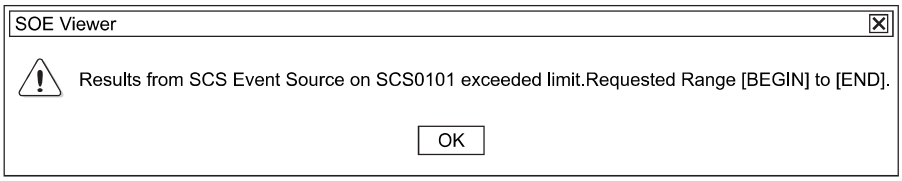

Figure I4.3.5-4 Warning dialog box

Click the [OK] button to close the Warning dialog box.

I4.4 Master database offline download

During master database offline download, the master database stored in the SENG is loaded to an SCS. Since the downloaded SCS database is identical to the master database, it is possible to download the information downloaded previously to the SCS even while changing the work database of an SCS project.

Use this download function to once again download the database that was previously downloaded; in the case, for example, when the CPU module of an SCS is replaced. This download is not required when one of a pair of redundant CPU modules is replaced.

Procedure for master database offline download

What to do before master database offline download

Use the SCS security level operation function to set the SCS security level to Level 0.

Start the master database offline download

1. Select [Controller] from the [Tools] menu of SCS Manager.
   The [Controller] launcher menu appears.
2. From the Controller Launcher menu, select [Reset SCS] > [Master Database Offline Download].
   The master database offline download confirmation dialog box appears.

TIP

- If the SCS security level is Level 1 or Level 2, a message prompting to set the security level to Level 0 is notified and the download ends with an error. Set the security level to Level 0, and start the master database offline download.
- If the I/O Lock window or Inter-SCS Communication Lock window is left open when you start master database offline download, an error message appears and the download processing ends.

3. Click [OK].
4. Set a new password for changing the SCS security level.

I4.5 NIU maintenance port setting tool

The NIU maintenance port setting tool is used in the following cases:

- To disable the NIU maintenance ports of all N-IO nodes on a per station basis in a batch
- To disable the NIU maintenance ports on a per node basis
- To enable the NIU maintenance ports on a per node basis

This section describes how to use the NIU maintenance port setting tool.

Rights to execute the NIU maintenance port setting tool

The NIU maintenance port setting tool can be executed by the logged-in Windows user who belongs to any of the following Windows groups: PSF_MAINTENANCE, PSF_MAINTENANCE_LCL, PSF_ENGINEER and PSF_ENGINEER_LCL.

To disable the NIU maintenance ports of all N-IO nodes on a per station basis in a batch

1. On the Hardware Configuration Tree View of the SCS State Management window, select the station for which the maintenance ports of NIU are to be disabled in a batch.
2. Select [Disable Maintenance port] in the [Operation] menu. Or, click the [Disable Maintenance port] button on the toolbar.
   The NIU Maintenance Port Setting Tool window appears.

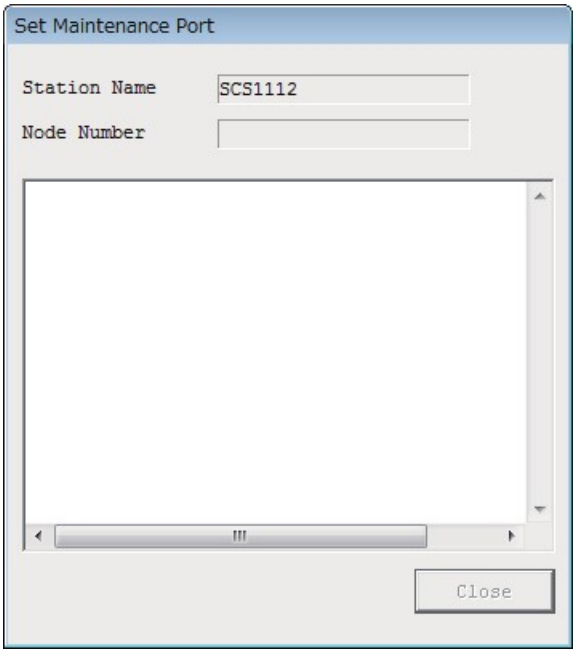

Figure I4.5-1 NIU Maintenance Port Setting Tool window

   The execution result is displayed in the message area once the processing is complete.

3. Click [Close].
   The NIU Maintenance Port Setting Tool window is closed.

To disable the NIU maintenance ports on a per node basis

1. On the Hardware Configuration Tree View of the SCS State Management window, select the N-IO node for which the maintenance port of NIU is to be disabled.

2. Select [Disable Maintenance port] in the [Operation] menu. Or, click the [Disable Maintenance port] button on the toolbar.
   The NIU Maintenance Port Setting Tool window appears.

   The execution result is displayed in the message area once the processing is complete.

3. Click [Close].
   The NIU Maintenance Port Setting Tool window is closed.

To enable the NIU maintenance ports on a per node basis

1. Check that the SCS security level is Level 1 or 0 by using the SCS security level operation function.
2. On the Hardware Configuration Tree View of the SCS State Management window, select the N-IO node for which the maintenance port of NIU is to be enabled.
3. Select [Enable Maintenance port] in the [Operation] menu. Or, click the [Enable Maintenance port] button on the toolbar.
   The NIU Maintenance Port Setting Tool window appears.

   The execution result is displayed in the message area once the processing is complete.

4. Click [Close].
   The NIU Maintenance Port Setting Tool window is closed.

IMPORTANT

Set the security level of the SCS to 1 or 0 to enable the maintenance port of NIU. You cannot enable the maintenance port of NIU when the security level is 2.

Display of execution results

The following execution results are displayed in the message area when the NIU maintenance port setting tool is executed.

Table I4.5-1 Display of execution results

Display	Description
Succeeded	Successfully completed the configuration process of the maintenance port.
Skipped	Skipped the configuration process of the maintenance port.
Failed	Failed in the configuration process of the maintenance port.

When a node is specified (example):

```
Disabling NIU Maintenance Port start 2015/12/11 18:02:00
Station:SCS0101 Node:1 … Succeeded.
Disabling NIU Maintenance Port end 2015/12/11 18:02:01
```

When all nodes are set at a time (example):

```
Disabling NIU Maintenance Port start 2015/12/11 18:03:00
Station:SCS0101 Node:1 … Succeeded.
Station:SCS0101 Node:2 … Skipped.
Station:SCS0101 Node:3 … Skipped.
Disabling NIU Maintenance Port end 2015/12/11 18:02:03
```

When disabling the port for all nodes, the result is displayed only for the nodes that are defined.

The following cases result in Skipped or Failed, and an error message is displayed.

- Specified port is already enabled/disabled
- NIU is in maintenance mode
- Node failure
- N-ESB bus failure

I4.6 IOM Download tool

The IOM Download tool enables you to configure input/output modules by downloading input/output configuration information from the master database of an SCS project to the modules. Use the IOM Download tool in the following cases.

- After replacing failed input/output modules with normal modules.
- When resetting AIO/DIO modules for recovery from errors in the field. This is only applicable with SCS system program release number R3.02 or later.

The correct operation procedure, when to use the IOM Download tool, and precautions are included in the topic of the input/output module maintenance. Use the IOM Download tool according to the instructions of reference documents in this section.

TIP

With SCS system program release number R2.03 or later, you can choose to enable automatic download of configuration information whenever stand by AIO/DIO module in a dual redundant configuration is replaced. This setting is available in the SCS Constants Builder. If the automatic download is executed, you do not have to use the IOM Download tool.

SEE ALSO

For more information about input module recovery procedure, refer to:

G2.2.1, “Actions taken at input module error occurrence and recovery procedure” on page G2-12

For more information about output module recovery procedure, refer to:

G2.2.3, “Actions taken at output module error occurrence and recovery procedure” on page G2-15

For more information about I/O module maintenance procedure, refer to:

“■ Maintenance of I/O modules” on page I1-12

For more information about how to replace the I/O module of the FIO node, refer to:

E4.7, “Replacing FIO I/O modules” in Hardware User's Guide (IM 32P06C10-01EN)

For more information about how to replace the I/O module of the N-IO node, refer to:

E5.3, “Replacing N-IO I/O modules” in Hardware User's Guide (IM 32P06C10-01EN)

■ Configuring Input/Output modules by using the IOM Download tool

The IOM Download tool must be used for modules where the hardware is working properly. Follow these steps to configure an input/output module:

TIP

The input/output configuration information stored in the master database of the SCS project is downloaded by IOM download. So the information previously downloaded to the input/output module is downloaded again even if the SCS project is being changed.

1. In the SCS State Management window, select an input/output module whose status is Fail .
2. On the tool bar, click [IOM Load].
   The IOM Load dialog box appears.
3. Click [OK].
   The input/output configuration information is downloaded to the selected input/output module. The downloaded information is stored in the non-volatile memory of the input/output module. After that, the SCS starts the input/output modules.
4. Check the results of the IOM Download tool execution in the diagnostic information messages.

IMPORTANT

- The channels of the output module are in the Output Disable status after the module starts. To output signals from the module, put the channels to be in the Output Enable status by performing the Output enable operation. After all channels go into the Output Enable status, SCS operating mode is changed from Waiting Mode to Running Mode.
- When the IOM Download tool is executed, the communication program is downloaded to the communication module, and the module restarts. The Output Enable Operation is unnecessary for the communication module because the communication begins automatically.

SEE ALSO For more information about how to view diagnostic information messages, refer to:

H5.1, “Diagnostic Information window” on page H5-2

For more information about Output enable operation, refer to:

C8., “Output enable operation” on page C8-1

Automatic execution of IOM download

After replacing I/O module, you need to perform IOM download in order to set configuration information. However, you can specify automatic execution of IOM download in following conditions.

When automatic execution of IOM download is specified, and if a standby side of a duplexed AIO/DIO module is replaced in the SCS that is running for a purpose such as maintenance, the configuration information is automatically downloaded from the module on the control side to the replaced module. This operation is possible only when specification is done with the SCS Constants Builder. If it is not specified, manual IOM download is required after replacing the module on the standby side. You need to perform manual IOM download when replacing both sides of redundant AIO/DIO modules or AIO/DIO modules of single configuration.

Automatic IOM download is not performed for communication modules.

SEE ALSO For more information about setting procedures using SCS Constants Builder, refer to:

C1.2.6, “SCS Constants Builder” on page C1-21

IOM download automatic execution conditions

If a redundant module on the standby side is replaced, IOM download is automatically executed if the following conditions are met.

- Automatic IOM download is enabled in the SCS Constants Builder.
- The redundant AIO/DIO module on the control side is operating normally.
- The replaced redundant module on the standby side failed due to configuration error (*1)

*1: Except the case where the model names on the control and standby sides are different or the case of hardware failure (the STATUS LED of the module is OFF).

Operations during automatic IOM download

The SCS operates as follows while automatic IOM download is being executed.

- If multiple AIO/DIO modules on the standby side are replaced, the processing of automatic IOM download is executed sequentially on a one-by-one basis.

- Diagnostic information messages (No. 0475 and 0476) are notified at the start and completion of automatic IOM download.
- If an error occurs during automatic execution of IOM download, the diagnostic information message indicating erroneous termination of automatic IOM download (No. 477) is notified and the IOM download processing is aborted.

IMPORTANT

Do not remove and put back the applicable AIO/DIO module while automatic IOM download is being executed. If it is removed and put back, a major failure may occur in the module (the STATUS LED of the module becomes OFF).
Automatic download is completed in approximately 30 seconds after inserting the module on the standby side, and the diagnostic information message indicating completion of IOM download (No. 0476) is output. If you need to remove and put back a module, check the diagnostic information message indicating completion of IOM download in the Diagnostic Information window of the SCS Maintenance Support Tool before doing so.

If a major failure occurs due to erroneous removal and reinsertion, perform IOM download manually to the applicable AIO/DIO module, and then remove and reinsert the module after the completion.

- Automatic IOM download is not executed on AIO/DIO modules to which online change download of input/output parameters or manual IOM download are being executed. However, automatic IOM download to a different module is executed in parallel.
- If it is attempted to execute online change download of input/output parameters or manual IOM download on the applicable AIO/DIO modules for which automatic IOM download is being executed, an error occurs in the manual download.

I4.7 IOM Control Right Switching Tool

The IOM Control Right Switching Tool is used for switching between the control side and the standby side of the pair of AIO/DIO modules placed in redundant configuration. However, this tool can not be used for the redundantly configured communication modules.

This section explains the operation procedures.

Overview of the IOM Control Right Switching Tool

The IOM Control Right Switching Tool is used for switching between the control side and the standby side of the pair of AIO/DIO modules for which redundant configuration is specified. It is possible to perform a switching operation for one AIO/DIO module pair or one node in one operation.

This tool can be used when the SCS security level is 1 or 0.

TIP

The IOM Control Right Switching Tool is not used to display the status of AIO/DIO modules or to perform operations related to the status of AIO/DIO modules.

Precautions at starting the IOM Control Right Switching Tool

The IOM Control Right Switching Tool can be used even if the SCS project is opened in SCS Manager.

Note, however, that if a download operation and an AIO/DIO module control right switching operation are performed at the same time, an error occurs in one of the operations. Moreover, the control right of AIO/DIO modules cannot be switched during checking in/out in Version Control or executing the Master Database Restoring Function.

How to start the IOM Control Right Switching Tool

Double-click the following command in Windows Explorer to start the tool. (ProSafe-RS installation top folder) Specify \ProSafe-RS\YOKOGAWA\scs\tool\RHEToolIOSwitch.exe or, from the [Start] menu of Windows, select [Run...] and specify "RHEToolIOSwitch.exe." The main window of the IOM control right switching tool appears.

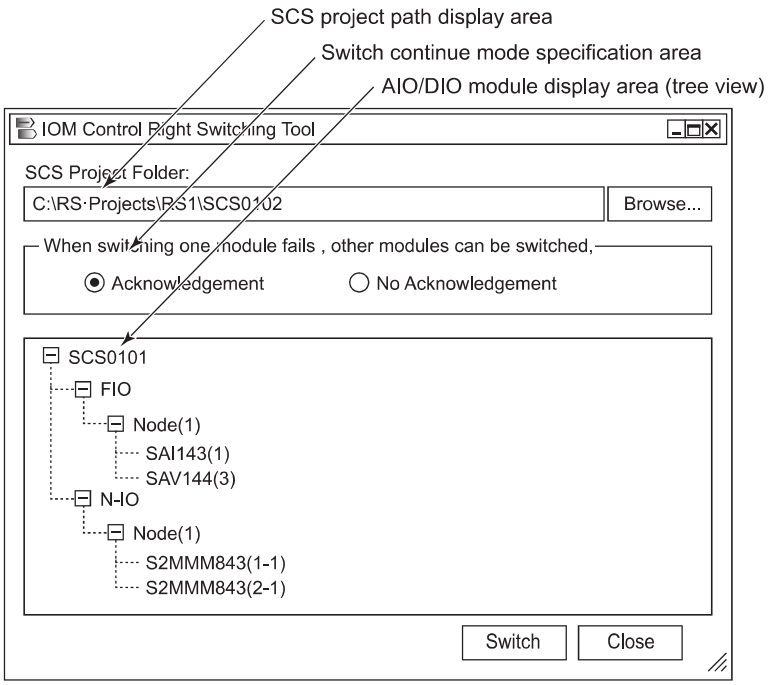

Figure I4.7-1 Main window of the IOM Control Right Switching Tool

Procedure to switch the control right of AIO/DIO modules

1. Specify the top folder of the SCS project in the SCS project path display area. The specified SCS project should be the one downloaded to the SCS. You can also select a folder from the folder selection dialog box that is displayed by clicking [Browse].
2. In the switch continue mode specification area, select [Acknowledgement] or [No Acknowledgement].
   You can select whether to display a confirmation dialog that appears during switching multiple AIO/DIO modules if switching fails for a certain AIO/DIO module, and the next AIO/DIO module is to be switched in continuation.
3. The redundant AIO/DIO modules in the SCS project, which is specified in the SCS project path display area, are displayed in a tree format in the AIO/DIO module display area.
   You can select either the AIO/DIO module or node for which the control rights are to be switched. Only one AIO/DIO module or one node can be selected at a time. You cannot select a station name, FIO or N-IO.
4. Click the [Switch] button. A confirmation dialog box appears.

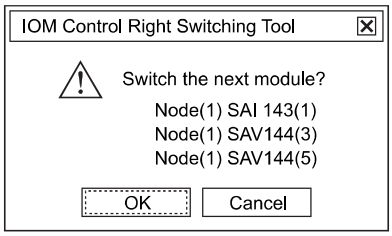

Figure I4.7-2 Confirmation dialog box

5. Click [OK]. The control right switching process of the AIO/DIO module starts, and the Message Display dialog box appears.

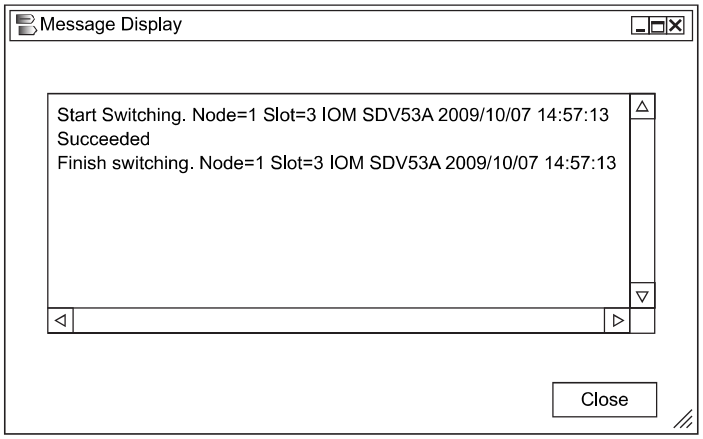

Figure I4.7-3 Message Display dialog box

   The Message Display dialog box shows the AIO/DIO module targeted for switching and the processing results, etc.

TIP

Select [Select All] from the pop-up menu displayed by right-clicking the mouse in order to select data displayed in the Message Display dialog box. Select [Copy] to copy the data.

6. When the switching operation is completed, click the [Close] button in the Message Display dialog box.
7. Click [Close] in the main window to exit the IOM Control Right Switching Tool.

I5. Procedures and precautions for adding a station or domain

This section describes the procedures and precautions that must be followed when you add a station or a domain to a Vnet/IP network in a star topology.

TIP

For information about the procedures and precautions when you add a station or a domain to a Vnet/IP network in a ring topology, contact YOKOGAWA.

SEE ALSO

For more information about the procedures and precautions for adding stations or adding domains in a CI Server integration configuration, refer to:

C5.2, “Procedures and precautions for adding a station or domain” in Integration with CI Server (IM 32P04D20-01EN)

Procedures and precautions for adding a Vnet/IP station

When adding a station to Vnet/IP network, follow the following procedure:

IMPORTANT

- If you add a station to a stand-alone ProSafe-RS system, special operation may be needed before adding it. For detailed procedure, refer to the link included at the end of this section.
- Before you add a station, make sure that there are no duplicate station addresses.
- Turn off the power of the additional station before you connect the cables.

SEE ALSO

For more information about procedure required before adding Vnet/IP station for a stand-alone ProSafe-RS system, refer to:

I6., “Procedures and precautions for adding or replacing Vnet/IP devices” on page I6-1

Case 1: When using existing Layer 2 switches (ports are available on existing Layer 2 switches)

1. In the Network Status Display dialog box on HIS, check that both buses are normal. (*1)
2. Make sure that the additional station is not powered.
3. Connect the Vnet/IP connector for BUS1 of the additional station to the Layer 2 switch for BUS1 with a cable. If the port on the Layer 2 switch is disabled, enable the port.
4. In the Network Status Display dialog box on HIS, check that both buses are normal.(*1)
5. Connect the Vnet/IP connector for BUS2 of the additional station to the Layer 2 switch for BUS2 with a cable. If the port on the Layer 2 switch is disabled, enable the port.
6. In the Network Status Display dialog box on HIS, check that both buses are normal.(*1)
7. Turn on the power of the additional station.
8. In the Network Status Display dialog box on HIS, check that both buses are normal.(*1)

*1: For a stand-alone ProSafe-RS system, use an SCS status display window (either SCS Status Overview or SCS State Management) of SCS Maintenance Support Tool on an SENG to check the bus status. When you call up the SCS status display window, select the project of a running SCS and then call up the window.

TIP Alternatively, you can add a station to Layer 3 switches directly instead of Layer 2 switches.

Case 2: When you need to add Layer 2 switches (no ports are available on existing Layer 2 switches)

Firstly, carry out steps 1 to 11 as shown below to add Layer 2 switches for BUS1 and BUS2. Next, carry out the procedure for "Case 1" above to add a station.

1. In the Network Status Display dialog box on HIS, check that both buses are normal.(*1)
2. Disconnect the cable between any one of the existing stations and a Layer 2 switch for BUS1.
3. Connect the additional Layer 2 switch for BUS1 to the existing Layer 2 switch for BUS1 with a cable.
4. Turn on the power of the Layer 2 switch that you have added.
5. Connect the existing station that you have disconnected at step 2 to the newly added Layer 2 switch for BUS1 with a cable.
6. In the Network Status Display dialog box on HIS, check that both buses are normal.(*1)
7. Disconnect the cable between any one of the existing stations and a Layer 2 switch for BUS2.
8. Connect the additional Layer 2 switch for BUS2 and the existing Layer 2 switch for BUS2 with a cable.
9. Turn on the power of the Layer 2 switch that you have added.
10. Connect the existing station that you have disconnected at step 7 to the newly added Layer 2 switch for BUS2 with a cable.
11. In the Network Status Display dialog box on HIS, check that both buses are normal.(*1)
12. Add a station according to the procedure for "Case 1".

*1: For a stand-alone ProSafe-RS system, use an SCS status display window (either SCS Status Overview or SCS State Management) of SCS Maintenance Support Tool on an SENG to check the bus status. When you call up the SCS status display window, select the project of a running SCS and then call up the window.

Procedures and precautions for adding a Vnet/IP domain

Follow these steps when you want to add a domain to a Vnet/IP network.

IMPORTANT

Make sure that there are no duplicate station addresses (domain number + station number) in the system.

Case 1: When using existing Layer 3 switches (ports are available on existing Layer 3 switches)

Firstly, carry out steps 1 to 5 as shown below to configure Layer 3 switches for BUS1 and BUS2. Next, add stations by following the procedures in "Procedures and precautions for adding a Vnet/IP station."

1. In the Network Status Display dialog box on HIS, check that both buses are normal. (*1)
2. Make the necessary settings on the existing Layer 3 switch for BUS1. If the port on the Layer 3 switch is disabled, enable the port.
3. In the Network Status Display dialog box on HIS, check that both buses are normal. (*1)

4. Make the necessary settings on the existing Layer 3 switch for BUS2. If the port on the Layer 3 switch is disabled, enable the port.
5. In the Network Status Display dialog box on HIS, check that both buses are normal. (*1)
6. Add stations for the new domain by following the procedures in "Procedures and precautions for adding a Vnet/IP station."

*1: For a stand-alone ProSafe-RS system, use an SCS status display window (either SCS Status Overview or SCS State Management) of SCS Maintenance Support Tool on an SENG to check the bus status. When you call up the SCS status display window, select the project of a running SCS and then call up the window.

Case 2: When you need to add Layer 3 switches (no ports are available on existing Layer 3 switches)

Firstly, carry out steps 1 to 7 as shown below to add Layer 3 switches for BUS1 and BUS2. Next, add stations by following the procedures in "Procedures and precautions for adding a Vnet/IP station."

1. In the Network Status Display dialog box on HIS, check that both buses are normal. (*1)
2. Make the necessary settings on the Layer 3 switch for BUS1 that you are going to add.
3. Connect the additional Layer 3 switch for BUS1 to an existing Layer 2 or Layer 3 switch for BUS1 with a cable.
4. In the Network Status Display dialog box on HIS, check that both buses are normal. (*1)
5. Make the necessary settings on the Layer 3 switch for BUS2 that you are going to add.
6. Connect the additional Layer 3 switch for BUS2 to an existing Layer 2 or Layer 3 switch for BUS2 with a cable.
7. In the Network Status Display dialog box on HIS, check that both buses are normal. (*1)
8. Add stations for the new domain by following the procedures in "Procedures and precautions for adding a Vnet/IP station."

*1: For a stand-alone ProSafe-RS system, use an SCS status display window (either SCS Status Overview or SCS State Management) of SCS Maintenance Support Tool on an SENG to check the bus status. When you call up the SCS status display window, select the project of a running SCS and then call up the window.

I6. Procedures and precautions for adding or replacing Vnet/IP devices

This section describes the procedures and precautions that must be followed when you add or replace a Vnet/IP device in a Vnet/IP domain of CENTUM integration system or a stand-alone ProSafe-RS system.

The Vnet/IP device is a generic name of the following devices:

- Processor module of SCS for Vnet/IP and FCS for Vnet/IP
- Vnet/IP interface card (Model: VI702)

TIP

The replacement of a Vnet/IP device includes not only replacement of a Vnet/IP station, but also replacement of a VI702 card and a processor module.

SEE ALSO

For more information about procedure and precaution after adding or replacing Vnet/IP devices in a CI server integration system, refer to:

C5.3, “Procedures and precautions for adding or replacing Vnet/IP devices” in Integration with CI Server (IM 32P04D20-01EN)

Precautions for adding or replacing Vnet/IP devices

The following problems may occur if the necessary procedures are not performed when you add the Vnet/IP device to a Vnet/IP domain or when you replace the Vnet/IP device in a Vnet/IP domain.

- Message issued by SCS cannot be received.
- Inter-SCS safety communication is disabled.

If these problems occur, perform the following operation.

Procedures after adding or replacing Vnet/IP devices of CENTUM integration system

For CENTUM integration system, if you add or replace the Vnet/IP device while all the Vnet/IP stations in the Vnet/IP domain that you want to add or replace the Vnet/IP device are turned off, follow the steps described below after you add or replace the Vnet/IP device.

TIP

If there is a powered-on Vnet/IP station on the Vnet/IP domain, the procedure is not necessary.

1. Start the computer with system builders of CENTUM VP first. If the domain does not contain a computer with system builders, start the computer with system builders in other domain first.
2. Start a station other than the computer with system builders in the domain.
3. Start System View, select a station in the domain, right-click, and select [Domain Properties] on the shortcut menu.
   Domain Properties appears.

TIP

You can select a station other than the one that you started in the step 2.

4. Click [OK].
   A dialog box appears, asking you to download Domain Properties.

5. Click [OK].
   The information of Domain Properties is reflected to the stations that have been started in the domain.
6. Start the stations that have been turned off in the domain.
   The information of Domain Properties is reflected to them.

TIP If you did not start the computer with system builders first, download Domain Properties immediately after you start the computer with system builders.

Procedures before adding or replacing Vnet/IP devices of stand-alone ProSafe-RS system

For stand-alone ProSafe-RS system that is not connected to CENTUM VP or CI Server, in advance of addition or replacement, clear the setting information of the Vnet/IP device that will be joined to the Vnet/IP domain by addition or replacement.

Procedures before adding or replacing VI702

Before adding or replacing SENG, or replacing VI702 of SENG, make sure to clear the setting information of VI702.

SEE ALSO For more information about procedure of clearing the setting information of VI702, refer to:

Appendix 2., “Procedure for Erasing VI702 Internal Settings” in Installation Guide (IM 32P01C50-01EN)

Procedures before adding or replacing processor module

If the SCS or processor module to be added or replaced has ever been used by another system, clear the processor module setting information before adding or replacing SCS or replacing the processor module. If it has never been used by another system, there is no need to clear the setting information.

SEE ALSO For more information about procedure of replacing a processor module that includes the procedure of clearing the setting information, refer to:

E4.2, “Replacing processor module” in Hardware User's Guide (IM 32P06C10-01EN)

Appendix 1. Settings for node, module, and channel

This section explains the settings for node, module, and channel. These settings can be done in the Safety I/O Editor or in IOM Definition Editor; however, this section explains how to do it in each tab of I/O Parameter Builder.

Appendix 1.1 Setting items for nodes

The following are the node settings of the Node tab in I/O Parameter Builder for input/output.

- Node number:
- Component Number
- Node Interface Unit
- Extends node bus
- Extends to
- N-IO Node Connection
- Enable External Alarm Input
- Normal Value
- Comment

Each node setting item is explained in detail as follows.

Node Number

This is the node number for which the module is mounted.

Component Number

This is a comment related to node layout information. Any character string of up to 8 single-byte characters or 4 double-byte characters can be entered.
This setting item is not downloaded to an SCS.

This item can be changed online.

Node Interface Unit: SCSP3, N-IO node

This is the model name of the bus module for node interface unit.

Extends Node Bus: SCSP3, SCSL2, and SCSP2

You can specify whether or not to extend nodes by the optical ESB bus repeater. For the remote node installed via the optical ESB bus repeater, you must select [Yes] and specify the distance in [Extends To]. If you do not make this setting, the data from the nodes and SOE data will not be updated correctly. If [Yes] is set for this item on CPU nodes, a build error will occur.

- Yes: Node extension by an optical ESB bus repeater is applied
- No: Node extension by an optical ESB bus repeater is not applied (default)

This setting item can be changed online.

Extends To: SCSP3, SCSL2, and SCSP2

You can specify the distance from a CPU node to a safety node unit and to an N-IO node. It is only valid if [Yes] is selected in the specification of node extension distance [Extends Node Bus].

- Range: 5 to 50 km (default: 5 km)
- Setting unit: 5 km

This item can be changed online.

Extends Node Bus : SCSP1

You can specify whether or not to extend nodes by the optical ESB bus repeater. To extend a node, select [Yes] and specify the distance in [Extends To]. A build error will occur if you select [Yes] for this item when [Optical ESB Bus Repeater] on the SCS Constants Builder is set to [No]. A build error will also occur if [Yes] is set for this item on CPU nodes.

- Yes: Node extension by an optical ESB bus repeater is applied
- No: Node extension by an optical ESB bus repeater is not applied (default)

This setting item can be changed online.

TIP

In the case of nodes equipped with ALR111, ALR121, or ALE111 for Modbus slaves, if 10 km or longer is specified in [Maximum Extension Distance] on the SCS Constants Builder, select [Yes] and specify the node extension distance in [Extends To].

Extends To: SCSP1

You can specify the distance from a CPU node to a safety node unit. It is only valid if [Yes] is selected in the specification of node extension distance [Extends Node Bus].
A build error will occur if the node extension distance is longer than [Maximum Extension Distance] defined on the SCS Constants Builder.

If default (0) is specified, it is regarded as if the node is at the position specified by [Maximum Extension Distance] defined on the SCS Constants Builder.

- Range: 0 to 50 km (default: 0)
- Setting unit: 5 km

This item can be changed online.

IMPORTANT

Be sure to specify the extension distance according to the actual node extension distance. If no specification is made for SCSP1, load fluctuation of CPU becomes large if input/output modules and/or bus fail.

N-IO Node Connection: SCSP3, FIO node

You can specify whether to connect the N-IO node to the path from the CPU node to FIO node.

- Yes: Connects the N-IO node to the path from the CPU node to FIO node.
- No: Does not connect the N-IO node to the path from the CPU node to FIO node (default).

This setting can be changed online.

Enable External Alarm Input: SCSP3, N-IO node

You can specify whether or not to use alarm input from an external device.

- Yes: Alarm input from an external device is used.
- No: Alarm input from an external device is not used (default).

This setting can be changed online.

Normal Value: SCSP3, N-IO node

You can specify the normal value to 0 or 1 for the alarm input if [Yes] is specified for [Enable External Alarm Input].

- 0: 0 is the normal value.
- 1: 1 is the normal value (default).

This setting can be changed online.

Comment

This is a comment related to the node. Any character string of up to 24 single-byte characters or 12 double-byte characters can be entered.
This setting item is downloaded to an SCS.

This setting item can be changed via online change download.

Appendix 1.2 Settings for modules

The following are the settings in the module tab of I/O Parameter Builder.

Node Number

This item displays the node number in which the I/O module is mounted.

Unit Number: N-IO I/O module

This item displays the unit number in which the I/O module is mounted.

Slot Number

This item displays the slot number in which the I/O module is mounted.

Device

The model name of the I/O module is displayed.

Base Plate: N-IO I/O module

You can select the base plate model for which the I/O module is mounted.

Table Appendix 1.2-1 Available base plate models

I/O module model	Base plate model	Description
S2MMM843, S2MDV843	S2BN1D	Standard base plate (default)
	S2BN_D	Base plate for barrier

TIP

If the base plate model is changed, all the channel items set for the module are initialized.

Dual-Redundant

This item displays whether the input/output module is placed in single configuration or redundant configuration. Input/output modules are placed in redundant configuration using an odd-numbered slot and the adjacent even-numbered slot (the odd number + 1).

Device Index

This is the device index assigned to the I/O module.

Comment

This is a comment related to the input/output module. Any character string of up to 24 single-byte characters or 12 double-byte characters can be entered.
This setting item is not downloaded to an SCS, so changing the definition does not affect input/output processing.

This item can be changed online.

Device Reset Function (per module): SAI143/L1AI143

This item specifies whether or not to use the device reset function.

- Enable: Uses the device reset function.

- Disable: Does not use the device reset function. (Default)

This setting is displayed when using an SCS project newly created with a version of SENG that is R4.03.00 or later.

SEE ALSO For more information about engineering for resetting the Smoke and Heat Detector, refer to:

A3.4.4, “Engineering regarding the device reset function and alarm suppression during device reset” in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

Command Line: analog output module

TIP Specify the command line using up to 256 single-byte characters. If the command line is not set, the default value will be used for each applicable item. The format is as follows.

Item name = Data value, Item name = Data value, ...

SOOP (Output open detection level setting)

This item specifies an output open (OOP) detection level. An open circuit error is recognized when the readback value of an output falls below the set value. The default is 0.00085 A.

Format

- SOOP=0.001

Parameter

- Output open detection level
  You need to specify an output open detection level in amperes (A).

  SOOP < Output value at fault (fail-safe value)

  If tight-shut output is specified : SOOP < Tight-shut output value

  If tight-shut output is not specified : SOOP < Power-on output value (0.00125 A)

- This item can be changed via online change download. Note, however, that IOM download is also performed at the same time.

Software Filter: digital input module, N-IO I/O module (DI channel only)

The software filter is applied for reducing the influence of noises. An integer between 0 and 10 can be selected as the filter setting value. The default setting is 1.

With this filter, the discrete input chattering signals can be sifted out so as to prevent from error actions.

The filter setting value multiplied by 10 ms (sampling period) is the filter time. The chattering signals occurred within this filter time will be eliminated.

As an example, if the filter setting value is 2, the chattering signals shorter than 20 ms (2x10 ms) will be eliminated.

- If the filter setting value is 0, the noise signals will not be filtered thus PV varies with the noise signals. In general, the filter setting value should not be set to 0.

This item can be changed via online change download. Note, however, that IOM download is also performed at the same time.

Automatically Delete Noisy Events (Automatically delete SOE event): digital input module, N-IO I/O module (DI channel only)

You can specify whether or not to delete events automatically if many events that are targets of SOER occur.
If a channel repeatedly generates too many events, the events from other channels may be lost. This function can be used to restrict events per channel and the above problem can be avoided. If the number of events that have occurred during the time specified in [SOE Deletion Schedule] exceeds the number of events specified in [Number of SOE Events], all subsequent events are discarded. For example, if [SOE Deletion Schedule] is set to 1.0 second and [Number of SOE Events] is set to 3, and if three or more events have occurred within 1 second, then the fourth and subsequent events occurring within 1 second are automatically discarded. However, if the last event is different from the current status of the DI, a pseudo event is generated to indicate the DI status.

- Yes (Delete):
  Automatically delete events if many events occur.
- No (Do not delete):
  Do not delete events even if many events occur (default).

This item can be changed via online change download. Note, however, that IOM download is also performed at the same time.

SOE Deletion Schedule (SOE event period): digital input module, N-IO I/O module (DI channel only)

You can specify the time period setting for [Automatically Delete Noisy Events] in units of seconds. This setting is enabled if [Yes (Delete)] is selected for [Automatically Delete Noisy Events].
Select either 0.5, 1.0, 1.5, 2.0, 2.5, 3.0 or 3.5 seconds. The default value is 1.0 second.

This item can be changed via online change download. Note, however, that IOM download is also performed at the same time.

Number of SOE Events: digital input module, N-IO I/O module (DI channel only)

You can specify the number of events for [Automatically Delete Noisy Events]. This setting is enabled if [Yes (Delete)] is selected for [Automatically Delete Noisy Events].
Select either 3 or 5. The default value is 3 events.

This item can be changed via online change download. Note, however, that IOM download is also performed at the same time.

Appendix 1.3 Settings for channel items

The following are the settings in the channel tab of I/O Parameter Builder.

Appendix 1.3.1 Common display items for channels

The following items are displayed commonly for all AIO/DIO modules with channel parameters in I/O Parameter Builder.

Channel Number

This is the channel number displayed in I/O Wiring View of SCS Manager. It is sequential number starting from 1.

Wiring Position

This is the channel name that is displayed in I/O Wiring View of SCS Manager. It is determined by device index and channel identification number. The channel identification number used for wiring position is sequential number starting from 0. The wiring position of the input modules is prefixed with %IU while the wiring position of the output modules is prefixed with %QU.

Example:

In the case of a 16-channel input module: %IU1.0, %IU1.1, ... %IU1.14, %IU1.15

In the case of a 8-channel output module: %QU3.0, %QU3.1, ... %QU3.6, %QU3.7

I/O Variable Name

This is the name of I/O variables assigned to the channel.

Direction: AIO/DIO module of FIO

This item indicates whether a signal is an input or output signal.

Comment

This is a comment for an I/O variable specified in Dictionary View (*1)of SCS Manager.

*1: The comment for the I/O variable specified in Dictionary View of SCS Manager is displayed as the comment for the wired channel. Up to 64 characters can be specified for the variable comment, but only 32 characters are retained in SCS database; therefore, make sure not to specify more than 32 characters. Channel comments for unused channels (unconnected channels) are not displayed.
Comments for DI/DO variables are the variables used as identifiers of SOE.

TIP

If comments for DI/DO variables are changed in Dictionary View of SCS Manager, discrepancies occur due to the input/output definition changes, and it becomes necessary to perform online change download to the SCS. Since this changes only the definitions in the databases of the SCS (no changes are made to the parameters of the DI/DO modules themselves), the inputs and outputs are not influenced by the online change download.

Signal Type: AIO/DIO module of N-IO

This item specifies type and direction of the I/O signal. Selection of the signal type can be different depending on the classified signal category that is specified.

Table Appendix 1.3.1-1 Signal type

Signal category	Signal type	Description
AI	Current Input	Select this item if HART communication function is not used (default).
	Current Input (HART Communication)	Select this item if HART communication function is used.
AO	Current Output	Select this item if HART communication function is not used (default).
	Current Output (HART Communication)	Select this item if HART communication function is used.
DI	Status Input	Only one DI signal type (default)
DO	Status Output	Use one channel (default).
	1.3A Status Output	Use two consecutive channels. When the settings for one channel (for example channel no. 3) are configured, the same contents are set automatically for the succeeding channel (for example channel no. 4). This item cannot be selected for the module mounted in the base plate for barrier.
	2.0A Status Output	Use three consecutive channels. When the settings for one channel (for example channel no. 3) are configured, the same contents are set automatically for the two succeeding channels (for example channels no. 4, 5). This item cannot be selected for the module mounted in the base plate for barrier.

IMPORTANT

When using S2MMM843 or S2MDV843 in an explosion protection system, refer to the following document without fail because the approved values of the explosion protection parameters are different depending on the signal type.

ProSafe-RS/ProSafe-RS Lite Explosion Protection (TI 32S01J30-01E)

P&ID Tag Name

This is a comment that the user can specify in order to make it easy to identify information drawn on a P&ID drawing with the channel.

For FIO, the comment should be written within 16 single-byte characters or 8 double-byte characters. For N-IO, the comment should be written within 32 single-byte characters or 16 double-byte characters. This setting item can be omitted.

Appendix 1.3.2 Settings for the AI channel

The following are the settings for the AI channel in I/O Parameter Builder.

Table Appendix 1.3.2-1 Settings for the AI channel

Setting items	Online change download (*1)	IOM download (*2)	Remarks
Channel Number (Specify Channel Number)	-	-	-
Wiring Position (Specify Wiring Position)	-	-	-
I/O Variable Name (Specify I/O Variable Name)	-	-	-
Direction (Specify Direction)	-	-	-
Comment (Specify Comment)	-	-	-
Time to Chattering Recovery Notice (s) (Specify Time to Chattering Recovery Notice)	Yes	No	-
Connection Method (Specify Connection Method)	Yes	Yes	-
Device OFF-ON Variable Name (Specify Device OFF-ON Variable Name)	Yes	No	-
Reset Group ID (Specify Reset Group ID)	Yes	No	-
Input Processing at Fault (Specify Input Processing at Fault)	Yes	No	-
Input Value at Fault (Specify Input Value at Fault)	Yes	No	-
Input Processing at Transmitter Fault (Specify Input Processing at Transmitter Fault)	Yes	No	-
Signal Conversion (Specify Signal Conversion)	Yes	No	For SAT145/ L1AT145 and SAR145/L1AR145, the IOM download is run.
Low Limit (Specify Low Limit)	Yes	Yes	-
High Limit (Specify High Limit)	Yes	Yes	-
Unit (Specify Unit)	No	No	-
Detect IOP (High) (Specify Detect IOP (High))	Yes	No	-
Detect IOP (Low) (Specify Detect IOP (Low))	Yes	No	-
Threshold of IOP (High) % (Specify Threshold of IOP (High) %)	Yes	No	-
Threshold of IOP (Low) % (Specify Threshold of IOP (Low) %)	Yes	No	-

Table Appendix 1.3.2-1 Settings for the AI channel (Table continued)

Setting items	Online change download (*1)	IOM download (*2)	Remarks
Detect Transmitter Fault (High) (Specify Detect Transmitter Fault (High))	Yes	No	-
Detect Transmitter Fault (Low) (Specify Detect Transmitter Fault (Low))	Yes	No	-
Threshold of Transmitter Fault (High) % (Specify Threshold of Transmitter Fault (High) %)	Yes	No	-
Threshold of Transmitter Fault (Low) % (Specify Threshold of Transmitter Fault (Low) %)	Yes	No	-
Field Power Diagnosis (Specify Field Power Diagnosis)	Yes	Yes	-
Reference Junction Compensation (Specify Reference Junction Compensation)	Yes	Yes	-
Burnout (Specify Burnout)	Yes	Yes	-
P&ID Tag Name (Specify P&ID Tag Name)	Yes	No	-
Command Line (Specify Command Line)	Yes	No	-

*1: Indicates whether the setting can be changed by online change downloading.
Yes: The setting can be changed by online change downloading.
No: Online change downloading is not required.
- : Not a target

*2: Indicates whether the IOM downloading is performed with the online change downloading.
Yes: The IOM downloading is performed together with the online change downloading.
No: The IOM downloading is not performed together with the online change downloading.
- : Not a target

Each of setting items that are not explained as common items is explained as follows.

Time to Chattering Recovery Notice (s) (Time to Chattering Recovery Notice)

This item is used to suppress the chattering alarm.

Set the time by which to delay display of the system alarm for recovery of a channel error of an input module. When an error is recovered during the alarm suppression period, SCS monitors whether the normal status persists for the amount of time set for this item. Alarm suppression is continued if an error occurs during the set time, while an error recovery system alarm is displayed if an error does not occur.

The chattering alarm suppression function is disabled when this time is set to 0.

Setting range: 0 to 120 seconds

Default: 0

IMPORTANT

This item can be used with SCS projects created using version R4.03.00 or later with SENG on which a CENTUM integration configuration license has been reflected.

Connection Method: AIO/DIO module of N-IO

- For the AIO/DIO module that is mounted in the standard base plate

You can set the connection method between field device and AIO/DIO module. The default is 2-Wire.

- For the AIO/DIO module that is mounted in the standard base plate for barrier
  You can set the connection method between barrier and AIO/DIO module. The default is 4-Wire.

Device OFF-ON Variable Name: SAI143/L1AI143, SAV144/L1AV144, and S2MMM843

You can specify a BOOL-type variable to switch OFF/ON of the power supply of the Smoke and Heat Detector. The fault detection status is reset by switching the device off and on. With S2MMM843, you can only set the variable when the connection method is 2-Wire.

When using SAI143 or SAV144, this item is displayed when using an SCS project newly created with a version of SENG that is R4.03.00 or later.

SEE ALSO For more information about engineering for resetting the Smoke and Heat Detector, refer to:

A3.4.4, “Engineering regarding the device reset function and alarm suppression during device reset” in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

Reset Group ID: SAI143/L1AI143, SAV144/L1AV144, and S2MMM843

An ID used, when multiple Smoke and Heat Detectors are to be reset, to interpret the channels of the Smoke and Heat Detectors being reset at the same time as being in the reset status. SCS manages whether the channels are in the reset status in units of each reset group ID. With S2MMM843, you can only set this ID when the connection method is 2-Wire.

Set the same reset group ID for channels to be interpreted as being in the reset status at the same time. Even in cases when there are no Smoke and Heat Detectors to be reset at the same time, set a reset group ID that is not in use with other channels. However, set this value to 0 if you will not be using the alarm suppression function during device reset nor the function block HSDTR.

This setting is displayed when using an SCS project newly created with a version of SENG that is R4.03.00 or later.

- Setting range: 0 to 1000 (default: 0)

SEE ALSO For more information about engineering for resetting the Smoke and Heat Detector, refer to:

A3.4.4, “Engineering regarding the device reset function and alarm suppression during device reset” in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

Input Processing at Fault

This item specifies an input processing to be used when an input fault is detected or when [Input Processing at Fault] is selected in [Input Processing at Transmitter Fault].
You can specify [Hold] or [Fixed Value].

The input faults that can be detected include the following: Errors on both sides of the path from the CPU to an analog input module, errors in analog input modules, channel errors, IOP and field wiring errors (transmitter errors are not included).

- Hold:
  The value before the fault was detected is retained.
- Fixed Value (specified input value):
  The input value specified in [Input Value at Fault] is set (default).

Input value at fault (%)

This is the value set as an input value instead of process value if [Fixed Value] is selected in [Input Processing at Fault] (the value is used as an input value at error occurrence).

For SAI143/L1AI143, SAV144/L1AV144, and S2MMM843

You can specify the input value at error occurrence (%) in the range from -25.0 to 125.0. The default value is 0.0 %.

Even if the [Signal Conversion] is set to [SQRT], this setting value is used as the input value at error occurs. (The value set here will not be square-rooted when used as the input value.)

For SAT145/L1AT145 and SAR145/L1AR145

You can specify the input value at error occurrence (%) in the range from -1000.0 to 1000.0. The default is 100.0%.

Input Processing at Transmitter Fault: SAI143/L1AI143, SAV144/ L1AV144, and S2MMM843

This is the value set as the input value if a transmitter error is detected (a value used as an input value at error). This item is only enabled for current inputs.

- Input Processing at Fault:
  Follow the setting of [Input Processing at Fault] if a transmitter error occurs (default).
- Raw Data:
  The raw data from the input module is set as the input value.

Signal Conversion

You can specify the conversion method of the input signal.

For SAI143/L1AI143, SAV144/L1AV144, and S2MMM843

- LINEAR (No Conversion):
  The physical range specified by the "Low Limit" and "High Limit" (mA or V) is converted to 0 to 100 (%) data (default).
- SQRT:
  After LINEAR conversion, input range checks are performed (against the IOP high limit/low limit and transmitter fault high limit/low limit). Then, the square root is calculated and the result is converted to a data value of 0 to 100 (%).

  The square-root conversion is illustrated as follows:

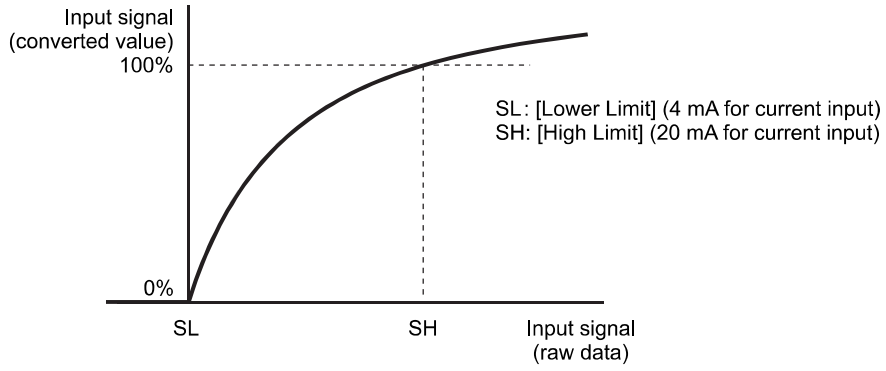

Figure Appendix 1.3.2-1 SQRT

For SAT145/L1AT145 and SAR145/L1AR145

Table Appendix 1.3.2-2 Input signal conversion for the thermocouple/mV input module (SAT145/ L1AT145)

Selection	Explanation of signal conversion
Type K	Temperature conversion Type K (default)
Type E	Temperature conversion Type E
Type T	Temperature conversion Type T
Type J	Temperature conversion Type J
Type R	Temperature conversion Type R
Type S	Temperature conversion Type S
Type B	Temperature conversion Type B
Type N	Temperature conversion Type N
mV Input -20 to 80 mV (%)	No temperature conversion. However, the physical range (mV) set in "High Limit" and "Low Limit" is converted to 0 to 100% data.
mV Input -100 to 150 mV (%)	
mV Input -5 to 25 mV (%)	
TC Input -20 to 80 mV (V)	No temperature conversion. Voltage value entries are directly applied to input valuables.
TC Input -100 to 150 mV (V)	
TC Input -5 to 25 mV (V)	

Table Appendix 1.3.2-3 Input signal conversion for the resistance temperature detector input module (SAR145/L1AR145)

Selection	Explanation of signal conversion
PT100	Temperature conversion Type PT100 (default)
JPT100	Temperature conversion Type JPT100
PT50	Temperature conversion Type PT50
PT200	Temperature conversion Type PT200
PT500	Temperature conversion Type PT500
PT1000	Temperature conversion Type PT1000
Ni100 (DIN)	Temperature conversion Type Ni100 (DIN)
Ni120 (MINCO)	Temperature conversion Type Ni120 (MINCO)
RTD Input 0 to 800 ohm (%)	No temperature conversion. However, the physical range (ohm) set in "High Limit" and "Low Limit" is converted to 0 to 100% data.
RTD Input 0 to 4000 ohm (%)	
RTD Input 0 to 800 ohm (ohm)	No temperature conversion. Resistor value entries are directly applied to input valuables.
RTD Input 0 to 4000 ohm (ohm)	

High Limit/Low Limit

These are the upper limit values and lower limit values of the measured range in the terminal.

For SAI143/L1AI143, SAV144/L1AV144, and S2MMM843

Values between 0 and 100% are assigned to the specified measurement range. The measurement range can only be changed for voltage input modules.

Table Appendix 1.3.2-4 High Limit value/Low Limit value

Input type	Module model	Low limit value of range	High limit value of range
Current input	SAI143/L1AI143	4	20
	S2MMM843	4	20
Voltage input	SAV144/L1AV144	1.000 to 10.000 (default is 1)	1.000 to 10.000 (default is 5)

For SAT145/L1AT145 and SAR145/L1AR145

The upper and lower limits are determined based on the combination of the signal conversion type and the engineering unit symbol. They are shown according to the module type and engineering unit symbol.

Table Appendix 1.3.2-5 Range upper and lower limits for the thermocouple/mV input module (SAT145/L1AT145) (engineering unit symbol C)

Signal conversion	Low limit value of range	High limit value of range
Type K	-200	1200
Type E	-200	900
Type T	-200	350
Type J	-40	750
Type R	0	1600
Type S	0	1600
Type B	600	1700
Type N	-200	1200

Table Appendix 1.3.2-6 Range upper and lower limits for the thermocouple/mV input module (SAT145/L1AT145) (engineering unit symbol F)

Signal conversion	Low limit value of range	High limit value of range
Type K	-300	2200
Type E	-300	1700
Type T	-300	650
Type J	-40	1400
Type R	0	2900
Type S	0	2900
Type B	1100	3100
Type N	-300	2200

Table Appendix 1.3.2-7 Range upper and lower limits for the thermocouple/mV input module (SAT145/L1AT145) (engineering unit symbol K)

Signal conversion	Low limit value of range	High limit value of range
Type K	100	1500
Type E	100	1200
Type T	100	600

Continues on the next page

Table Appendix 1.3.2-7 Range upper and lower limits for the thermocouple/mV input module (SAT145/ L1AT145) (engineering unit symbol K) (Table continued)

Signal conversion	Low limit value of range	High limit value of range
Type J	200	1000
Type R	250	1900
Type S	250	1900
Type B	900	2000
Type N	100	1500

Table Appendix 1.3.2-8 Range upper and lower limits for the thermocouple/mV input module (SAT145/ L1AT145) (engineering unit symbol mV)

Signal conversion	Low limit value of range	High limit value of range
mV Input -20 to 80 mV (%)	-20 (default) to 80	-20 to 80 (default)
mV Input -100 to 150 mV (%)	-100 (default) to 150	-100 to 150 (default)
mV Input -5 to 25 mV (%)	-5 (default) to 25	-5 to 25 (default)
TC Input -20 to 80 mV (V)	-20 (default) to 80	-20 to 80 (default)
TC Input -100 to 150 mV (V)	-100 (default) to 150	-100 to 150 (default)
TC Input -5 to 25 mV (V)	-5 (default) to 25	-5 to 25 (default)

Table Appendix 1.3.2-9 Range upper and lower limits for the resistance temperature detector input module (SAR145/L1AR145) (engineering unit symbol C)

Signal conversion	Low limit value of range	High limit value of range
PT100	-200	850
JPT100	-200	500
PT50	-200	850
PT200	-200	850
PT500	-200	850
PT1000	-200	850
Ni100 (DIN)	-60	250
Ni120 (MINCO)	-80	320

Table Appendix 1.3.2-12 Range upper and lower limits for the resistance temperature detector input module (SAR145/L1AR145) (engineering unit symbol ohm)

Signal conversion	Low limit value of range	High limit value of range
RTD Input 0 to 800 ohm (%)	0 (default) to 800	0 to 800 (default)
RTD Input 0 to 4000 ohm (%)	0 (default) to 4000	0 to 4000 (default)
RTD Input 0 to 800 ohm (ohm)	0 (default) to 800	0 to 800 (default)
RTD Input 0 to 4000 ohm (ohm)	0 (default) to 4000	0 to 4000 (default)

Unit

This is the unit for input signal.

For SAI143/L1AI143, SAV144/L1AV144, and S2MMM843

This is determined by the type of input module.

For SAT145/L1AT145 and SAR145/L1AR145

The available types depend on symbol conversion.

- Thermocouple/mV input module (SAT145/L1AT145)

Table Appendix 1.3.2-13 Engineering unit symbols for the thermocouple/mV input module (SAT145/L1AT145)

Engineering unit symbol	Description	Symbol conversion
C	Celsius (default)	Type K, Type E, Type T, Type J, Type R, Type S, Type B, Type N
F	Fahrenheit	
K	Kelvin	
mV	Millivolt	mV input (%), TC input (V)

- Resistance temperature detector input module (SAR145/L1AR145)

Table Appendix 1.3.2-14 Engineering unit symbols for the resistance temperature detector input module (SAT145/L1AT145)

Engineering unit symbol	Description	Symbol conversion
C	Celsius (default)	PT100, JPT100, PT50, PT200, PT500, PT1000, Ni100 (DIN), Ni120 (MINCO)
F	Fahrenheit	
K	Kelvin	
ohm	Ohm	RTD input (%), RTD input (Ω)

Detect IOP (High)

This item specifies whether to detect an input open status when the process value (the value after the input signal was converted (0 to 100%)) exceeds the threshold. When the signal conversion setting is [SQRT], the value prior to the square-root calculation is used as the process value (hereinafter referred to as "process value"). The input value at fault is the value specified by the setting item "Input Processing at Fault".

- No:
  An input open circuit error is not detected.
- Yes:
  If a process value exceeds the threshold value, an input open circuit error is detected and the data status of the input variable connected to the applicable channel becomes BAD (default). The threshold value is specified with [Threshold of IOP (High) %].

Detect IOP (Low)

This item specifies whether or not to detect an input open circuit error if a process value falls below the threshold value. The input value at fault is the value specified by the setting item "Input Processing at Fault."

- No:
  An input open circuit error is not detected.
- Yes:
  If a process value falls below the threshold value, an input open circuit error is detected and the data status of the input variable connected to the applicable channel becomes BAD (default). The threshold value is specified with [Threshold of IOP (Low) %].

Threshold of IOP (High) %

This item specifies the upper limit level at which an input open circuit is detected. This item can only be enabled when [Yes] is specified for [Detect IOP (High)]. The process value exceeding the Detect IOP (High) level means input open.

For SAI143/L1AI143, SAV144/L1AV144, and S2MMM843

The default value is 112.5% (for current input) and 106.3% (for voltage input).

Note that the following checks are performed even if [No] is specified for [Detect IOP (High)]:

- An error occurs if a value is entered such that the value of [Threshold of IOP (High) %] becomes equal to or smaller than the value of [Threshold of Transmitter Fault (High) %].
- An error occurs if a value outside the setting range of the analog input module is entered.
  «Setting range»

  Current input: -18.75% to 118.75% (1 to 23 mA)

  However, in the case of SAI143-H style S3 or later, L1AI143-H, or S2MMM843, -23.75% to 118.75% (0.2 to 23 mA)

  Voltage input: Varies depending on the range specification (0.1 to 11 V).
  - If the range is set to 1 to 10 V: -10% to 111.1% (0.1 to 11 V)
  - If the range is set to 1 to 5 V: -22.5% to 125% (0.1 to 6 V)

In addition to the above checks, the following inputs are checked:

- Number of characters: Up to 7 single-byte characters
- Number of decimal places: Within 2 digits

For SAT145/L1AT145 and SAR145/L1AR145

The default value is 106.3%.

Note that the following checks are performed even if [No] is specified for [Detect IOP (High)]:

- If you input a value outside of the -1000.0% to 1000.0% range, an error occurs.
- If you input a value outside of the -25.0% to 125% range, a warning is displayed when saving.

In addition to the above checks, the following input checks are performed:

- Number of characters: Up to 7 single-byte characters
- Number of decimal places: Within 2 digits

Threshold of IOP (Low) %

This item specifies the lower limit level at which an input open circuit is detected. This item can only be enabled when [Yes] is specified for [Detect IOP (Low)]. The process value less than the Detect IOP (Low) level means input open.

For SAI143/L1AI143, SAV144/L1AV144, and S2MMM843

Specify a value between -25.0% to 125.0%. The default value is -6.3%.

Note that the following checks are performed even if [No] is specified for [Detect IOP (Low)].

- An error occurs if a value is entered such that the value of [Threshold of IOP (Low) %] level becomes equal to or greater than the value of [Threshold of Transmitter Fault (Low) %].
- An error occurs if a value outside the setting range of the analog input module is entered.
  «Setting range»

  Current input: -18.75% to 118.75% (1 to 23 mA)

  However, in the case of SAI143-H style S3 or later, L1AI143-H, or S2MMM843, -23.75% to 118.75% (0.2 to 23 mA)

  Voltage input: Varies depending on the range specification (0.1 to 11 V).
  - If the range is set to 1 to 10 V: -10% to 111.1% (0.1 to 11 V)
  - If the range is set to 1 to 5 V: -22.5% to 125% (0.1 to 6 V)

In addition to the above checks, the following inputs are checked:

- Number of characters: Up to 7 single-byte characters
- Number of decimal places: Within 2 digits

For SAT145/L1AT145 and SAR145/L1AR145

Specify a value between -1000.0% to 1000.0%. The default value is 0.0% for resistance temperature detector input and -6.3% for thermocouple input.

Note that the following checks are performed even if [No] is specified for [Detect IOP (Low)].

- If you input a value outside of the -1000.0% to 1000.0% range, an error occurs.
- If you input a value outside of the -25.0% to 125% range, a warning is displayed when saving.

In addition to the above checks, the following input checks are performed:

- Number of characters: Up to 7 single-byte characters

- Number of decimal places: Within 2 digits

Detect Transmitter Fault (High): SAI143/L1AI143, SAV144/L1AV144, and S2MMM843

This item specifies whether or not to detect a transmitter error if a process value exceeds the threshold value. This item is only enabled for current inputs. The input value at fault is the value specified by the setting item "Input Processing at Transmitter Fault".

- No:
  A transmitter error is not detected.
- Yes:
  If the process value exceeds the threshold value, a transmitter error is detected and the data status of the input variable connected to the applicable channel becomes BAD (default). The threshold value is specified with [Threshold of Transmitter Fault (High) %].

Detect Transmitter Fault (Low): SAI143/L1AI143, SAV144/L1AV144, and S2MMM843

This item specifies whether or not to detect a transmitter error if a process value falls below the threshold value. This item is only enabled for current inputs. The input value at fault is the value specified by the setting item "Input Processing at Transmitter Fault".

- No:
  A transmitter error is not detected.
- Yes:
  If the process value falls below the threshold value, a transmitter error is detected and the data status of the input variable connected to the applicable channel becomes BAD (default). The threshold value is specified with [Threshold of Transmitter Fault (Low) %].

Threshold of Transmitter Fault (High) %: SAI143/L1AI143, SAV144/L1AV144, and S2MMM843

This item specifies the upper limit level at which a transmitter error is detected. This item is enabled only when [Yes] is specified for [Detect Transmitter Fault (High)]. This item is only enabled for current inputs. It is judged that a transmitter error has occurred if the process value exceeds this setting.
The default value is 106.3%.

Note that the following checks are performed even if [No] is specified for [Detect Transmitter Fault (High)]:

- An error occurs if a value is entered such that the value of [Threshold of IOP (High) %] becomes equal to or smaller than the value of [Threshold of Transmitter Fault (High) %].
- An error occurs if a value outside the setting range of the analog input module is entered.
  «Setting range»

  Current input: -18.75% to 118.75% (1 to 23 mA)

  However, in the case of SAI143-H style S3 or later, L1AI143-H, or S2MMM843, -23.75% to 118.75% (0.2 to 23 mA)

Threshold of Transmitter Fault (Low) %: SAI143/L1AI143, SAV144/L1AV144, and S2MMM843

This item specifies the lower limit level at which a transmitter error is detected. This item is enabled only when [Yes] is specified for [Detect Transmitter Fault (Low)]. This item is only

enabled for current inputs. It is judged that a transmitter error has occurred if the process value falls below this setting.
The default value is -1.25%.

Note that the following checks are performed even if [No] is specified for [Detect Transmitter Fault (Low)]:

- An error occurs if a value is entered such that the value of [Threshold of IOP (Low) %] level becomes equal to or greater than the value of [Threshold of Transmitter Fault (Low) %].
- An error occurs if a value outside the setting range of the analog input module is entered. «Setting range»

  Current input: -18.75% to 118.75% (1 to 23 mA)

  However, in the case of SAI143-H style S3 or later, L1AI143-H, or S2MMM843, -23.75% to 118.75% (0.2 to 23 mA)

TIP

If it is specified to detect input open (IOP+, IOP-) and transmitter errors (TRNS+, TRNS-), diagnostic information messages indicating the occurrence of an alarm and the recovery are notified as follows:

- If the PV value changes, causing the alarm status to change, a diagnostic information message corresponding to the status after change is notified.
- The diagnostic information message indicating recovery from the generated alarm is notified only when the alarm status recovers to NR (normal). Messages indicating recovery from individual alarms, IOP+/IOP-/TRNS+/TRNS-, are not notified.

Following (1) to (7) are the Diagnostic information messages that are notified at the change of the PV value:

○ PV value before change
● PV value after change

(1) Occurrence of TRNS+
(2) Occurrence of IOP+ (No messages indicating recovery from TRNS+ are generated.)
(3) Occurrence of TRNS+ (No messages indicating recovery from IOP+ are generated.)
(4) Recovery from channel error
(5) Occurrence of IOP+ (No messages indicating occurrence of/recovery from TRNS+ are generated.)
(6) Recovery from channel error
(7) Occurrence of IOP+ (No messages indicating recovery from IOP- are generated.
No messages indicating occurrence of/recovery from TRNS- are generated.
No messages indicating occurrence of/recovery from TRNS+ are generated.)

Figure Appendix 1.3.2-2 Generation of diagnostic information messages

Field Power Diagnosis: SAI143/L1AI143 and SAV144/L1AV144

You need to specify the wiring type. It is used to determine the method of power supply diagnosis of the FIO input modules. Based on this setting, current input modules perform self-diagnosis on whether or not the power is supplied correctly to the field. This item is only enabled for current inputs.

IMPORTANT

Make sure that this setting matches with the 2-wire/4-wire setting that is made by using the setting pins in the analog input module. If the settings are different from those of the hardware, a channel error occurs in the case of single input for FIO module, or the control shifts to the standby module in the case of a dual-redundant input module configuration.

- None: Do not perform field power supply diagnosis.
- 2 wire:
  2-wire (Default: Diagnose that the power is supplied to the field. Diagnosis indicates normal if the power is supplied to the field device.) The input value at fault is the value specified by the setting item "Input Processing at Fault".
- 4 wire:
  4-wire (Diagnose that no power is supplied to the field. Diagnosis indicates normal if no power is supplied to the field device.) The input value at fault is the value specified by the setting item "Input Processing at Fault."

Reference Junction Compensation: SAT145/L1AT145 and SAR145/L1AR145

Specify whether or not to perform reference junction compensation. This item is only available in the thermocouple input module. However, it is not available when [mV Input], [TC Input], or [Type B] is specified for signal conversions.

- No:
  Reference junction compensation is not performed.
- Yes:
  Reference junction compensation is performed (default).

Burnout: SAT145/L1AT145 and SAR145/L1AR145

Specify the input operation when there is a disconnection. When detection of input open circuit errors is enabled and an input open circuit error is detected, the value specified in Input Processing at Fault is set as the input variable.

- Burnout upscale:
  Clamps the input to the upper limit specified by the module when there is a disconnection (default).
- Burnout downscale:
  Clamps the input to the lower limit specified by the module when there is a disconnection.
- No:
  Disables the burnout operation.

Command Line: AIO/DIO module of N-IO

TIP

Specify the command line with no more than 250 single-byte characters. If the command line is not set, the default value is used for each applicable item. The format is as follows:

Item name = Data value, Item name = Data value, ...

HARTPRI (HART communication master priority order setting)

You can specify whether to consider AIO/DIO module of N-IO as the primary master or the secondary master.

- Format
  HARTPRI=Yes
- Parameter
  Yes: The module is set as the primary master. (Default)

  No: The module is set as the secondary master.

For example, you can set the handy terminal as the secondary master when the module is set as the primary master.

HARTEVENT (notification setting for the changed status of HART device)

You can specify whether or not to notify the changed status of HART device. If No is set, the changed status that is received by N-IO I/O module is not notified to the SCS. If Current Input (HART Communication) or Current Output (HART Communication) is selected as signal type, the default is Yes. If other signal type is selected, the default is No.

- Format
  HARTEVENT=No
- Parameter
  Yes: The changed status of HART device is notified.

  No: The changed status of HART device is not notified.

HARTPERIOD (setting of detection period by I/O module for the changed status of HART device)

This item sets the period in which the AIO/DIO module of N-IO detects detailed information of HART device by using Command #48. This can be set only when HARTEVENT=Yes.

- Format
  HARTPERIOD=30
- Parameter
  Select either 15, 30, 45, or 60 seconds. The default is 30 seconds.

Appendix 1.3.3 Settings for the AO channel

The following are the settings for the AO channel in I/O Parameter Builder.

Table Appendix 1.3.3-1 Items set for each channel of analog output module

Setting items	Online change download (*1)	IOM download (*2)	Remarks
Channel Number (Specify Channel Number)	-	-	-
Wiring Position (Specify Wiring Position)	-	-	-
I/O Variable Name (Specify I/O Variable Name)	-	-	-
Direction (Specify Direction)	-	-	-
Comment (Specify Comment)	-	-	-
I/O Shutoff Switch (Specify I/O Shutoff Switch)	Yes	Yes	-
Output Shutoff Switch (Specify Output Shutoff Switch)	Yes	Yes	-
Output Processing at Fault (Specify Output processing at fault)	Yes	Yes	-
Output Value at Fault (Specify Output value at fault)	Yes	Yes	-
Tight-shut/Full-open (Specify Tight-shut/Full-open)	Yes	Yes(*3)	-
Tight-shut Value (Specify Tight-shut Value)	Yes	Yes	-
Full-open Value (Specify Full-open Value)	Yes	No	-
Detect Short Circuit (Specify Detect Short Circuit)	Yes	Yes	-
Detect Disconnection (Specify Detect Disconnection)	Yes	Yes	-
P&ID Tag Name (Specify P&ID Tag Name)	Yes	No	-
Command Line (Specify Command Line)	Yes	Yes	For the AIO/DIO module of N-IO, the IOM download does not take place.

*1: Indicates whether the setting can be changed by online change downloading.
Yes: The setting can be changed by online change downloading.
No: Online change downloading is not possible
- : Not a target

*2: Indicates whether the IOM downloading is performed with the online change downloading.
Yes: The IOM downloading is performed together with the online change downloading.
No: The IOM downloading is not performed together with the online change downloading.
- : Not a target

*3: IOM downloading may be performed according to the modified contents.

The setting items that are not explained above as common items are explained below.

I/O Shutoff Switch: AIO/DIO module of N-IO

Specifies whether or not to activate the I/O shutoff switch when a critical malfunction that can prevent normal output has occurred. If the I/O shutoff switch is activated, all channels of the corresponding module other than the AI channel (4-wire) are shut off.

- Enable:
  Activates the I/O shutoff switch when a critical malfunction such as an overcurrent occurs (default).
- Disable:
  Does not activate the I/O shutoff switch even when a critical malfunction occurs.

Output Shutoff Switch: analog output module of FIO

The output shutoff switch can be used to shutoff all the outputs of the module when the module encounters a critical malfunction for properly outputting signals, and the whole module becomes failure mode (Module HRDY OFF). Enable or disable this switch needs to be specified.

- Enable:
  Activate the Output Shutoff switch if a dangerous failure occurs (default).
- Disable:
  Do not activate the Output Shutoff switch even if a dangerous failure occurs.

Output Processing at Fault

This item needs to be specified so that when an error occurs in CPU module (both CPU modules in redundant configuration) or in the path from CPU to output module, the output module can act the specified processing for the output from the output channel to the field device.

- Hold:
  Hold the outputs upon detection of an error.
- Fixed Value:
  Change each output value to the value specified in [Output Value at Fault] upon detection of an error (default).

Output Value at Fault

This value is used as a fail-safe value (i.e., output value at fault) when [Output Processing at Fault] is set to [Fixed Value].

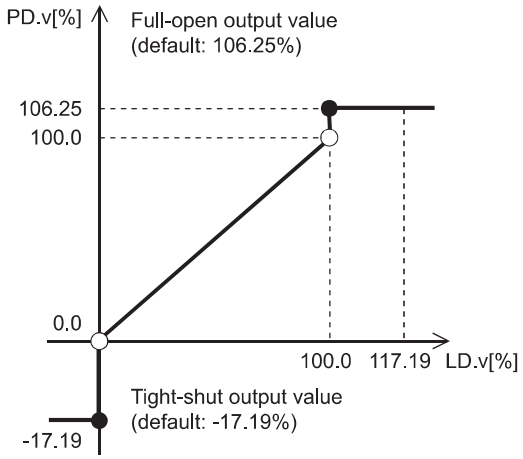
- Specify the value to be output upon error, in a range of -17.19 to 117.19 (%). The default value is -17.19 %. This setting is effective only when [Output Processing at Fault] is set to [Fixed Value].

The following input checks are performed.

- Range: -17.19 to 117.19 (%)
- Permitted characters: Single-byte numbers, decimal point, negative sign (-)
- Number of characters: Up to 6 single-byte characters
- Number of decimal places: Within 2 digits

Tight-shut/Full-open

Tight-shut/full-open is a function that reduces the actual output value to 0% or below when the manipulated output value is 0%, or increases the actual output value to 100% or above when the manipulated output value is 100%, in order to fully close or open the control valve firmly. Specify whether or not to enable this function.
If PRM (Plant Resource Manager) is used, set "Tight-shut/Full-open" to "Yes" and determine an appropriate tight-shut value for the connected device.



- Yes:
  Enable the tight-shut/full-open function (default). Specify a tight-shut value in [Tight-shut Value], and a full-open value in [Full-open Value].

The initial output value of the module (i.e., default initial value upon power-on) will be the same value of the tight-shut output.

- No:
  Disable the tight-shut/full-open function. The initial output value of the module (default initial value upon power-on) is fixed to -17.19% (1.25 mA).

The following graphs show the relationships of logical data (LD) and physical data (PD) when the data is normal, output is enabled, and output variable is not locked.

<Relationship of LD and PD with tight-shut specification>

<Relationship of LD and PD without tight-shut specification>

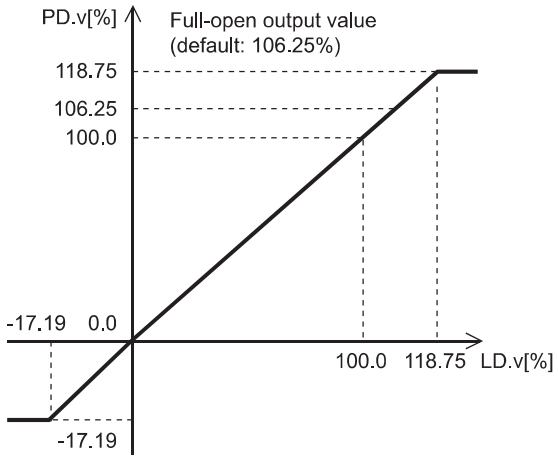


Figure Appendix 1.3.3-1 The following graphs show the relationships of logical data (LD) and physical data (PD) when the data is normal, output is enabled, and output variable is not locked.

Tight-shut Value

This item specifies in a range of -17.19 to 0 (%) the actual value to be output when the tight-shut/full-open function is specified and the output value is 0 %. The default is -17.19 % (1.25 mA). This setting is possible only when [Tight-shut/Full-open] is set to [Yes].
The following input checks are performed.

- Range: -17.19 to 0 (%)
- Permitted characters: Single-byte numbers, decimal point, negative sign (-)
- Number of characters: Up to 6 single-byte characters
- Number of decimal places: Within 2 digits

Full-open Value

This item specifies in a range of 100 to 117.19 (%) the actual value to be output when the tight-shut/full-open function is specified and the output value is 100%. The default is 106.25% (21 mA). This setting is possible only when [Tight-shut/Full-open] is set to [Yes]. To implement "reverse output", create the necessary application using the application logic.
The following input checks are performed.

- Range: 100 to 117.19 (%)
- Permitted characters: Single-byte numbers, decimal point
- Number of characters: Up to 6 single-byte characters
- Number of decimal places: Within 2 digits

Detect Short Circuit

This item specifies whether or not to detect short circuit. If a base plate for the barrier is used, it is fixed to No.

- Yes: Detect short circuit (default).
- No: Do not detect short circuit.

Detect Disconnection

This item specifies whether or not to detect open circuit.

- Yes: Detect disconnection (default).
- No: Do not detect disconnection.

Command Line

TIP

For the analog output module of FIO, specify the command with no more than 256 single-byte characters. For the AIO/DIO module of N-IO, specify the command with no more than 250 single-byte characters. If the command line is not set, the default value is used for each applicable item. The format is as follows:

Item name = Data value, Item name = Data value, ...

SCREG (short circuit detection level)

This item specifies a short circuit detection level. A short circuit is detected when the wiring resistance falls below the set value. By specifying a value greater than the wiring resistance as the short circuit detection level, a short circuit on a device terminal can be detected. The default value is 70 Ω.

- Format
  SCREG=100
- Parameter
  Specify an integer value for SCREG. The unit is ohms (Ω) and the specifiable range is 60 to 750 Ω. SCREG must satisfy the following condition:
  SCREG (short circuit detection level setting) > Wiring resistance (*1)

  *1: Add the resistance of KS cables, etc. to the wiring resistance.

IMPORTANT

If the current output value falls below -6.25 % (3 mA) due to the settings in [Output Value at Fault] and [Tight-shut Value], the short circuit detection operation becomes unstable in the range of SCREG setting ±20 Ω.

Therefore, considering the above characteristic and the actual wiring resistance, you need to set an appropriate SCREG value that allows the short circuit detection to be performed without fail.

If the default SCREG setting (SCREG=70) is used without setting the command line, a short circuit is not detected if the wiring resistance reaches or exceeds 90 Ω. However, a short circuit is detected without fail when the wiring resistance is 50 Ω or below.

Example:

When a device is connected by using a KS cable and SCREG is set to 70 Ω

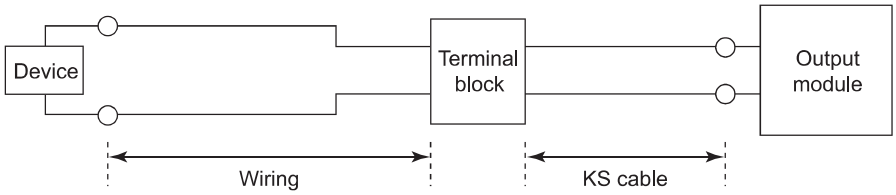

Figure Appendix 1.3.3-2 Example of a device connection by using a KS cable

- Add the resistance of a KS cable to the wiring resistance.
- If SCREG is set to 70 Ω, the following operations are performed according to the output current value:
  - 3 mA (-6.25%) or above
    There is an error of ±10 Ω. A short circuit is always detected if the wiring resistance is 60 Ω or below. A short circuit is not detected if the wiring resistance is 80 Ω or above.
  - 1 mA (-18.75%) or above, but below 3 mA
    There is an error of ±20 Ω. A short circuit is always detected if the wiring resistance is 50 Ω or below. A short circuit is not detected if the wiring resistance is 90 Ω or above.
  - Below 1 mA
    A short circuit is not detected.

TIP

The resistance value of a KS cable is 230 Ω/km while the resistance value of a standard cable (such as AWG20) is 23 to 50 Ω/km.

SOOP (Output open detection level): AIO/DIO module of N-IO

This item specifies an output open (OOP) detection level. An open circuit error is recognized when the readback value of an output falls below the set value. The default is 0.00085 A.

Format

- SOOP=0.001

Parameter

- Output open detection level
  You need to specify an output open detection level in amperes (A).

  SOOP < Output value at fault (fail-safe value)

  If tight-shut output is specified : SOOP < Tight-shut output value

  If tight-shut output is not specified : SOOP < Power-on output value (0.00125 A)
- This item can be changed via online change download. Note, however, that IOM download is also performed at the same time.

HARTPRI (HART communication master priority order settings): AIO/DIO module of N-IO

You can specify whether to consider AIO/DIO module of N-IO as the primary master or the secondary master.

- Format
  HARTPRI=Yes
- Parameter
  Yes: The module is set as the primary master. (Default)

  No: The module is set as the secondary master.

For example, you can set the handy terminal as the secondary master when the module is set as the primary master.

HARTEVENT (notification settings for the changed status of HART device): AIO/DIO module of N-IO

You can specify whether or not to notify the changed status of HART device. If No is set, the changed status that is received by N-IO I/O module is not notified to the SCS. If Current Input (HART Communication) or Current Output (HART Communication) is selected as signal type, the default is Yes. If other signal type is selected, the default is No.

- Format
  HARTEVENT=No
- Parameter
  Yes: The changed status of HART device is notified.

  No: The changed status of HART device is not notified.

HARTPERIOD (setting of detection period by I/O module for the changed status of HART device): AIO/DIO module of N-IO

This item sets the period in which the AIO/DIO module of N-IO detects detailed information of HART device by using Command #48. This can be set only when HARTEVENT=Yes.

- Format
  HARTPERIOD=30
- Parameter
  Select either 15, 30, 45, or 60 seconds. The default is 30 seconds.

Appendix 1.3.4 Settings for the DI channel

The following are the settings for the DI channel in I/O Parameter Builder.

Table Appendix 1.3.4-1 Items set for each channel of a digital input module

Setting items	Online change Download (*1)	IOM Download (*2)	Remarks
Channel Number (Specify Channel Number)	-	-	-
Wiring Position (Specify Wiring Position)	-	-	-
I/O Variable Name (Specify I/O Variable Name)	-	-	-
Direction (Specify Direction)	-	-	-
Comment (Specify Comment)	-	-	-
Input Processing at Fault (Specify Input Processing at Fault)	Yes	No	-
Detect Disconnection (Specify Detect Disconnection)	Yes	Yes	-
Detect Short Circuit (Specify Detect Short Circuit)	Yes	Yes	-
Detect LFD (Specify Detect LFD)	Yes	Yes	-
Pulse Test (Specify Pulse Test)	Yes	Yes	-
SOER (Setting for SOER) (Specify Trip Signal)	Yes	Yes	-
Trip Signal (Setting for SOER) (Specify Trip Signal)	Yes	No	-
P&ID Tag Name (Specify P&ID Tag Name)	Yes	No	-

*1: Indicates whether the setting can be changed by online change downloading.
Yes: The setting can be changed by online change downloading.
No: Online change downloading is not required.
- : Not a target

*2: Indicates whether the IOM downloading is performed with the online change downloading.
Yes: The IOM downloading is performed together with the online change downloading.
No: The IOM downloading is not performed together with the online change downloading.
- : Not a target

Each of setting items that are not explained as common items is explained as follows.

Input Processing at Fault

This item specifies a value that will be passed to the application logic instead of the input from the field if an error is detected in the input of the channel, including channel errors, DI module errors and errors in the path from the CPU to the DI module.

- 0: The input value is set to 0 at error detection (default).
- 1: The input value is set to 1 at error detection.
- Hold: The value immediately before the error was detected is retained when an error is detected.

Detect Disconnection (Open Circuit)

This item specifies whether to detect disconnection (open circuit). If a base plate for the barrier is used, it is fixed to [No].

- Yes: Detect disconnection.
- No: Do not detect disconnection (default). When the disconnection occurs, input value is 0 and the status is GOOD.

IMPORTANT

If [Yes] is set for [Detect Disconnection], disconnection errors can be detected. Make sure, however, to connect a wiring check adapter (SCB100) on the channel if you specify [Yes]. If you specify [Yes] without connecting the adapter, the SCS erroneously detects a disconnection error whenever the input value is OFF.

Detect Short Circuit

This item specifies whether or not to detect a short circuit in the wiring. If a base plate for the barrier is used, it is fixed to [No].

- Yes: Detect short circuit (default).
- No: Do not detect short circuit. When the short-circuit error occurs, input value is 1 and the status is GOOD.

IMPORTANT

If [Yes] is set for Detect Short Circuit, short-circuit errors can be detected (assuming short circuit with the power supply line). However, if you specify [Yes] , ensure to install a wiring check adapter (SCB110) in the channel. If you specify [Yes] without connecting the adapter, the SCS erroneously detects a short-circuit error whenever the input value is ON.

Detect LFD: AIO/DIO module of N-IO

This item specifies whether or not to detect line fault in the barrier.

- Type A, Type B: Line fault is detected.
- No: Line fault is not detected.

Pulse Test: digital input module of FIO

This item specifies whether or not to perform a pulse test (wiring check between the input channels using pulse output).

- Yes: Perform a pulse test (default)
- No: Do not perform the pulse test

IMPORTANT

If [Yes] is set for [Pulse Test], wiring short-circuit errors between input channels can be detected. Make sure, however, to connect a wiring check adapter (SCB110) to the channel if you specify [Yes] for a channel which receives NC input signals.. If you specify [Yes] without connecting the adapter, the SCS cannot detect inter-channel short circuit when the input value is ON.

SOER (setting for SOER)

This item specifies whether or not to accumulate events for SOER when a signal changes.

- Yes: Accumulate SOE events when a signal changes (default).
- No: Do not accumulate SOE events.

Trip Signal (setting for SOER)

This item specifies whether or not to regard an event as a trip occurrence. This setting is only enabled if [Yes] is set for [SOER].

- No (0):
  Changes are not regarded as a trip signal (default).
- OFF TRIP (1):
  A change to OFF is regarded as a trip signal and SOE data before and after a trip is stored in an SCS.
- ON TRIP (2):
  A change to ON is regarded as a trip signal and SOE data before and after a trip is stored in an SCS.

Appendix 1.3.5 Settings for the DO channel

The following are the settings for the DO channel in I/O Parameter Builder.

Table Appendix 1.3.5-1 Items set for each channel of a digital output module

Setting items	Online change download (*1)	IOM download (*2)	Remarks
Channel Number (Specify Channel Number)	-	-	-
Wiring Position (Specify Wiring Position)	-	-	-
I/O Variable Name (Specify I/O Variable Name)	-	-	-
Direction (Specify Direction)	-	-	-
Comment (Specify Comment)	-	-	-
Output Shutoff Switch (Specify Output Shutoff Switch)	Yes	Yes	-
DO Shutoff Switch (Specify DO Shutoff Switch)	Yes	Yes	-
Output Value in Detecting Error/Output Processing at Fault (*3) (Specify Output processing at fault)	Yes	Yes	-
Detect Disconnection (Specify Detect Disconnection)	Yes	Yes	-
Detect LFD (Specify Detect LFD)	Yes	Yes	-
Pulse Test (OFF) (Specify Pulse Test (OFF))	Yes	Yes	-
Pulse Test (ON) (Specify Pulse Test (ON))	Yes	Yes	-
Low Voltage Pulse Test (On) (Specify Low Voltage Pulse Test (On))	Yes	Yes	-
SOER (Setting for SOER) (Specify Trip Signal)	Yes	No	-
Trip Signal (Setting for SOER) (Specify Trip Signal)	Yes	No	-
P&ID Tag Name (Specify P&ID Tag Name)	Yes	No	-
Command Line (Specify Command Line)	No	No	This item does not need to be entered.

*1: Indicates whether the setting can be changed by online change downloading.
Yes: The setting can be changed by online change downloading.
No: Online change downloading is not required.
- : Not a target

*2: Indicates whether the IOM downloading is performed with the online change downloading.
Yes: The IOM downloading is performed together with the online change downloading.
No: The IOM downloading is not performed together with the online change downloading.
- : Not a target

*3: For FIO, Output Value in Detecting Error, and for N-IO, Output Processing at Fault

Each of setting items that are not explained as common items is explained as follows.

Output Shutoff Switch: digital output module of FIO

The output shutoff switch can be used to shutoff all the outputs of the module when the module encounters a critical malfunction such as the output is clutched to ON status, and the whole module becomes failure mode (Module HRDY OFF). If the Output Shutoff switch is activated, the output of all DO channels of the relevant module is set to OFF. This setting is not affected in the event of short circuit. For SDV526/L1DV526, this setting cannot be changed. It is fixed at Disable.

- Enable:
  Activate the Output Shutoff switch if a dangerous failure such as the output getting stuck in the ON status occurs (default).
- Disable:
  Do not activate the Output Shutoff switch even if a dangerous failure occurs.

DO Shutoff Switch: AIO/DIO module of N-IO

You can specify whether or not to activate the DO shutoff switch if a critical malfunction that can prevent normal output has occurred to the module. If the DO shutoff switch is activated, all DO channels of the corresponding modules are shut off.

- Enable:
  Activate the DO shutoff switch if a critical malfunction such as output stuck occurs (default).
- Disable:
  Do not activate the DO shutoff switch even if a critical malfunction occurs.

Output Value in Detecting Error/Output Processing at Fault

This item specifies a value output from the channel to the field if an error occurs on the CPU module (both CPU modules in redundant configuration) or in the path from CPU to output module. This definition is used as the fail-safe value set for the output variables. For SDV526/L1DV526, this setting cannot be changed. It is fixed at the default value.

- 0: Output 0 to the field at error detection (default).
- 1: Output 1 to the field at error detection.
- Hold: The value immediately before the error was detected is maintained.

TIP

For FIO, the name of this item is Output Value in Detecting Error, and for N-IO, it is Output Processing at Fault.

In AD Suite, however, specify a value in Output Processing at Fault even if it is FIO. The value is reflected in this item when you run Reflection.

Detect Disconnection (Open Circuit detection)

This item specifies whether to detect disconnection (open circuit). If a base plate for the barrier is used, it is fixed to No. To detect disconnection for AIO/DIO modules of N-IO, also set Low Voltage Pulse Test (On) to Yes.

- Yes: Detect disconnection (default)
- No: Do not detect disconnection

Detect LFD: AIO/DIO module of N-IO

This item specifies whether or not to detect line fault in the barrier.

- Type A, Type B: Line fault is detected.
- No: Line fault is not detected.

Pulse Test (OFF)

This item specifies whether to implement the off-edge pulse test. This item enables the use of the off-edge pulse output to test the wiring of the channel that may be clutched to ON status. For SDV526/L1DV526, this setting is fixed to No. For digital output modules other than SDV526/L1DV526, faults that can be detected are clutched-to-ON faults and short circuits between channels. Only clutched-to-ON faults can be detected for S2MMM843 and S2MDV843.

- Yes: Perform the off-edge pulse test (default)
- No: Do not perform the pulse test

Pulse Test (ON)

This item specifies whether to implement the on-edge pulse test. This item enables the use of the on-edge pulse output to test the wiring of the channel that may be clutched to OFF status. For SDV526/L1DV526, this setting is fixed to No. For digital output modules other than SDV526/L1DV526, faults that can be detected are clutched-to-OFF faults, short circuits between channels, and short circuits while an OFF signal is being output. Only clutched-to-OFF faults can be detected for S2MMM843 and S2MDV843.

- Yes: Perform the on-edge pulse test
- No: Do not perform the pulse test (default)

Low Voltage Pulse Test (On): AIO/DIO module of N-IO

This item specifies whether to implement low voltage pulse test (on). This item enables the use of the on-edge pulse output (5V) to test the wiring in order to detect open circuit and short circuit while an OFF signal is being output. To detect disconnection, set Detect Disconnection to Yes.

- Yes: Conduct the low voltage pulse test (on) (default)
- No: Do not conduct the low voltage pulse test

SOER (setting for SOER)

This item specifies whether or not to accumulate events for SOER when a signal changes.

- Yes: Accumulate SOE events when a signal changes.
- No: Do not accumulate SOE events (default).

Trip signal (setting for SOER)

This item specifies whether or not to regard an event as a trip occurrence. This setting is only enabled if [Yes] is set for [SOER].

- No (0):
  Changes are not regarded as a trip signal (default).
- OFF TRIP (1):
  A change to OFF is regarded as a trip signal and SOE data before and after a trip is stored in an SCS.
- ON TRIP (2):

A change to ON is regarded as a trip signal and SOE data before and after a trip is stored in an SCS.

Command Line

This item does not need to be entered.

Appendix 2. RS original engineering

RS original engineering is applied to SCS projects for which I/O list engineering is not performed. This section describes the engineering methods that are unique to RS original engineering. If you select the RS original engineering method, you cannot engineer using iDefine.

TIP

RS projects that include SCS projects that were created before introducing AD Suite can also be registered in AD Server.
The history management function of AD Server can be used on SCS projects that have been registered in AD Server.

SEE ALSO

For more information about history management function, refer to:

C2., “History management” in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about how to register RS projects to AD Server, refer to:

C1.2.3, “Registering RS projects in the AD project” on page C1-13

Appendix 2.1 Operations on SCS projects that are not registered in the AD project

In principle, RS projects, including SCS projects, must be registered in AD projects. However, in some cases, RS projects cannot be registered in AD projects because the timing of the modification does not fit or for other reasons. The actions to take in such a case are described as follows:

- Starting SCS Manager
- Backing up SCS Projects

Starting SCS Manager

Select [YOKOGAWA ProSafe] > [Workbench]. SCS Manager starts up.

TIP

- With Windows 10, select [ProSafe] > [Workbench].
- It is not possible to open SCS Manager and Version Control Tool, or to open SCS Manager and Master Database Restoring Function at the same time.
- For SCS projects that are engineered in RS original engineering and are registered in an AD project, you can start SCS Manager from AD Organizer. In System Structure Navigator, select the SCS and click the button for calling SCS Manager.

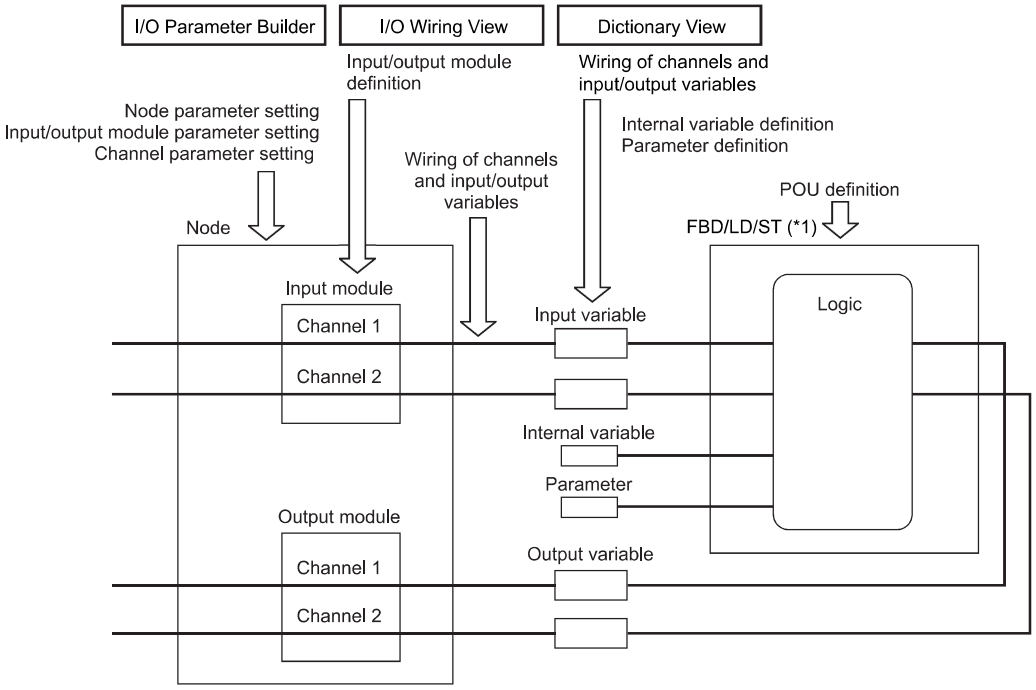
Backing up RS projects

When you back up all the folders under an RS project folder, all the SCS projects containing the implementation data of an application are also backed up.

The RS project backup shall be saved in external media, by saving folders below the RS project folder using Windows Explorer.

IMPORTANT

The RS project backup operation must be performed when the engineering function and SCS Maintenance Support Tool are not used.



When you choose the standard model of IT security, you need to logon to the PC with a user account that is authorized to access the ProSafe-RS related folders so as to perform backups.

Appendix 2.2 Definitions of inputs/outputs

When defining inputs and outputs, use Dictionary View, I/O Wiring View and I/O Parameter Builder to set the following items.

Table Appendix 2.2-1 Definitions of inputs and outputs

Definition	Description	Tool used
Input/output variable definition	Define input/output variables.	Dictionary View
Input/output module definition	Define the configuration of input/output modules. Specify the model and mounting position (node number and slot number) of a module, as well as redundancy.	I/O Wiring View
Wiring of channels and input/output variables	Assign input/output variables to channels.	
Node parameter setting	Set parameters for nodes.	I/O Parameter Builder
Input/output module parameter setting	Set parameters for input/output modules.	
Channel parameter setting	Set parameters for channels.	

*1: ST can be used for user-defined FB/FU only.

Figure Appendix 2.2-1 Definitions of inputs/outputs

SEE ALSO For more information about Dictionary View details, refer to:

"Dictionary View" in "Workbench" in the Workbench User's Guide

Input/Output definition operations

Input/output definitions are made using Dictionary View, I/O Wiring View and I/O Parameter Builder.

IMPORTANT

If you changed I/O definitions and saved them in I/O Wiring View, make sure to save them also in I/O Parameter Builder.

Make input/output definitions according to the following procedure.

1. Input/output variable definition
   Define input/output variables using Dictionary View.
2. Definitions of I/O modules
   You need to define I/O modules by using I/O Wiring View, and set the mounting positions of I/O modules (node number and slot number, or unit number) and whether to make them redundant or not.
3. Wiring of channels and input/output variables
   Use I/O Wiring View to associate the channels of the input/output module with the input/output variables.
4. Parameter settings

   Use I/O Parameter Builder to set parameters for nodes, input/output modules and channels.

TIP

Steps “1. Definitions of I/O variables” and “2. Definitions of I/O modules” can be performed independently; however, both steps must be performed before “3. Wiring of channels and I/O variables."

Steps “3. Wiring of channels and I/O variables” and “4. Parameter settings” can be performed independently in FIO I/O modules; however, steps must be performed in a sequence in universal type I/O modules. This is because the signal category is determined by wiring the channel and I/O variable in the universal type I/O module. You cannot set the parameter when the signal category is not determined because the parameter settings vary depending on the signal category.

Appendix 2.2.1 I/O Wiring View

I/O Wiring View is used to define input/output modules.

Make the following definitions in I/O Wiring View.

- Creation and deletion of input/output modules
- Specification of mounting positions of input/output modules
- Selection of redundant and single input/output module configurations
- Wiring of variables and channels

IMPORTANT

- When editing definitions in I/O Wiring View, close I/O Parameter Builder first.
- If you changed I/O definitions and saved them in I/O Wiring View, make sure to save them also in I/O Parameter Builder.

How to display I/O Wiring View

Select [I/O Wiring] from the [Project] menu of SCS Manager; I/O Wiring View appears.

I/O Wiring View window structure

I/O Wiring View consists of I/O Wiring Tree View that lists input/output modules and I/O Wiring Grid View that lists input/output variables that can be wired to channels.

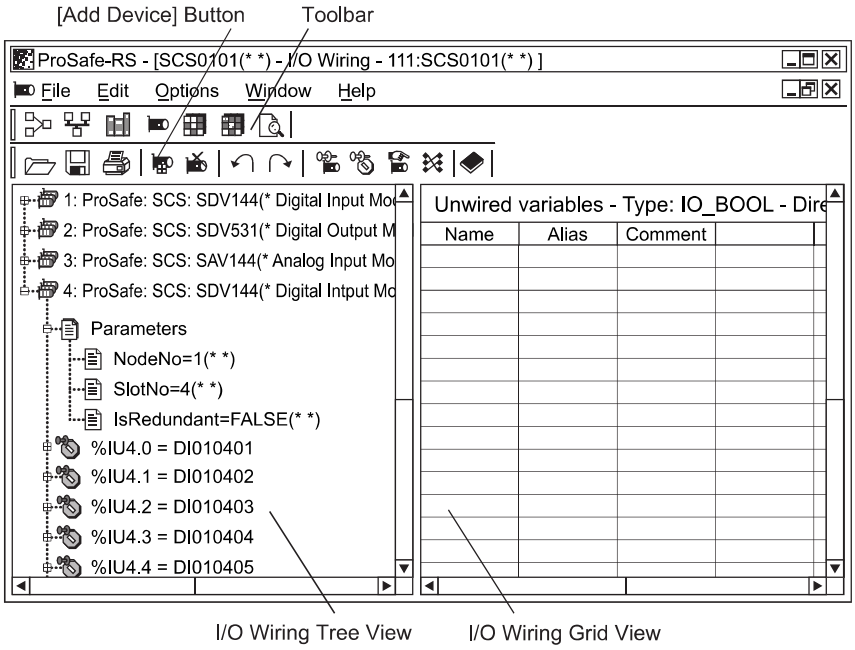


Figure Appendix 2.2.1-1 I/O Wiring View

SEE ALSO For more information about Dictionary View details, refer to:

"I/O Wiring View" in "Workbench" in the Workbench User's Guide

Setting items in I/O Wiring View

You need to set the following items in I/O Wiring View:

- Model of input/output module
- Device index
- Node number
- Unit number (for N-IO I/O module)
- Slot number
- Specification of redundancy
- Wiring of channels and input/output variables

However, to change the model of input/output module or device index, you need to first delete the model and then add the new setting.

Creation of Input/Output modules

To add input/output modules, click "Add Device" button in the toolbar. The Device Selection dialog box appears.

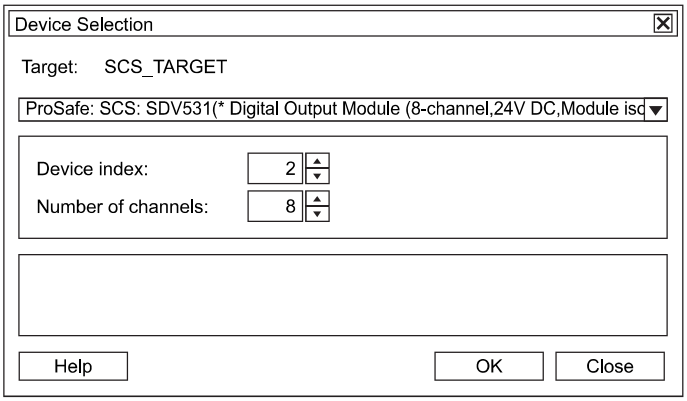

Figure Appendix 2.2.1-2 Device Selection dialog box

Adding AIO/DIO modules or communication modules

When adding an AIO/DIO module or communication module, specify the model of the module in I/O Wiring View.

AIO/DIO modules for SCS supporting SIL 3 that can be specified are as follows.

Table Appendix 2.2.1-1 AIO/DIO modules for SCS supporting SIL 3 that can be specified

AIO/DIO module model	Description
SAI143	Analog input module (4 to 20 mA, 16-channel, module isolation)
SAI143H	Analog input module (4 to 20 mA, 16-channel, module isolation, with HART communication)
SAV144	Analog input module (1 to 5 V/1 to 10 V, 16-channel, module isolation)
SAT145	Analog input module (thermocouple/mV, 16-channel, isolated channels)
SAR145	Analog input module (RTD, 16-channel, isolated channels)
SAI533H	Analog output module (4 to 20 mA, 8-channel output, module isolation, with HART communication)

Continues on the next page

Table Appendix 2.2.1-1 AIO/DIO modules for SCS supporting SIL 3 that can be specified (Table continued)

AIO/DIO module model	Description
SDV144	Digital input module (24 V DC, 16-channel, module isolation)
SDV521	Digital output module (24 V DC, 4-channel, module isolation)
SDV526	Digital output module (100 to 120 V AC, 4-channel, module isolation)
SDV531	Digital output module (24 V DC, 8-channel, module isolation)
SDV531L	Digital output module (24 V DC, 8-channel, module isolation, long distance type)
SDV53A	Digital output module (48 V DC, 8-channel, module isolation)
SDV541	Digital output module (24 V DC, 16-channel, module isolation)
S2MMM843	Analog digital I/O modules (16-channel, module isolation)
S2MDV843	Digital I/O modules (16-channel, module isolation)
SEC402/SEC401 (*1)	ESB bus coupler module
S2EN402/S2EN404 (*1)	N-ESB bus coupler module

*1: Set SEC402/SEC401 and S2EN402/S2EN404 to connect the CPU node and the node by using ESB bus or N-ESB bus. These are not AIO/DIO modules; however, they are described in the same table.

AIO/DIO modules for SCS supporting SIL 2 that can be specified are as follows:

Table Appendix 2.2.1-2 AIO/DIO modules for SCS supporting SIL 2 that can be specified

AIO/DIO module model	Description
L1AI143	Analog input module (4 to 20 mA, 16-channel, module isolation)
L1AI143H	Analog input module (4 to 20 mA, 16-channel, module isolation, with HART communication)
L1AV144	Analog input module (1 to 5 V/1 to 10 V, 16-channel, module isolation)
L1AT145	Analog input module (thermocouple/mV, 16-channel, isolated channels)
L1AR145	Analog input module (RTD, 16-channel, isolated channels)
L1AI533H	Analog output module (4 to 20 mA, 8-channel output, module isolation, with HART communication)
L1DV144	Digital input module (24 V DC, 16-channel, module isolation)
L1DV521	Digital output module (24 V DC, 4-channel, module isolation)
L1DV526	Digital output module (100 to 120 V AC, 4-channel, module isolation)
L1DV531L	Digital output module (24 V DC, 8-channel, module isolation, long distance type)
L1DV53A	Digital output module (48 V DC, 8-channel, module isolation)
L1DV541	Digital output module (24 V DC, 16-channel, module isolation)
L1EC402/L1EC401 (*1)	ESB bus coupler module

*1: Set L1EC402/L1EC401 to connect the CPU node and the node by using ESB bus. These are not AIO/DIO modules; however, they are described in the same table.

Communication modules that can be specified are as follows. The communication modules that can be specified differ depending on the communication type.

Table Appendix 2.2.1-3 Communication modules that can be specified

Communication module	Description	Communication modules that can be specified	
		For Modbus slave communication	For subsystem communication (*1)
ALR111	RS-232C communication module (2-Port)	ALR111	ALR111M

Continues on the next page

Table Appendix 2.2.1-3 Communication modules that can be specified (Table continued)

Communication module	Description	Communication modules that can be specified	
		For Modbus slave communication	For subsystem communication (*1)
ALR121	RS-422/RS-485 communication module (2-Port)	ALR121	ALR121M
ALE111 (*2)	Ethernet communication module (10BASE-T, 1-Port)	ALE111	ALE111M

*1: In I/O Wiring View and I/O Parameter Builder, names are displayed in this way. However, in other SENG windows and the HIS status display view, the final "M" is not displayed.
*2: When the CPU node of SCS is SSC10D or SSC10S, do not define ALE111.

TIP

- You can use SSB401, S2EN501, SNT401, SNT411, SNT501, and SNT511, without setting it in the I/O Wiring View.
- You can use L1SB401, L1NT401, L1NT411, L1NT501, and L1NT511, without setting it in the I/O Wiring View.

Device index

This is an identifier that is attached to I/O modules. Set a unique numeric value in the range of 0 to 65535. Mounting position of the I/O modules is independent; however, it is recommend to specify the relevant number for the indexes.

IMPORTANT

The index cannot be changed after creating I/O modules.

Number of channels

The number of channels in the defined input/output module is displayed.

Mounting position of Input/Output module and setting of redundancy

In I/O wiring tree view of I/O Wiring View, double-click [Parameters] of an I/O module. The I/O Parameters dialog box appears.
Set the mounting position (node number, unit number, and slot number) and whether or not to use a redundant configuration. You cannot set a redundant configuration for ALR121 that is used in ProSafe-SLS communication function.

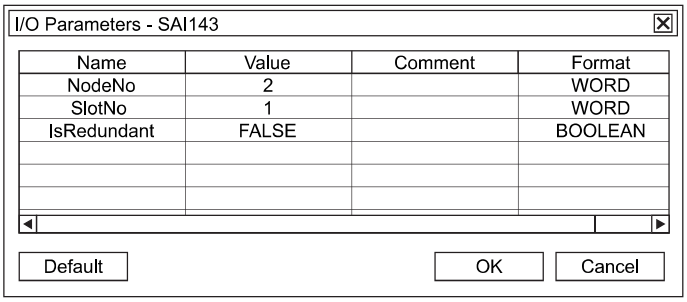

Figure Appendix 2.2.1-3 I/O Parameters dialog box

IMPORTANT

The I/O Parameters dialog box is used to specify the mounting position and redundancy. Parameters of input/output modules are specified in I/O Parameter Builder.

● Node number (NodeNo), unit number (UnitNo), and slot number (SlotNo)

You need to set the mounting position of the I/O module. The allowed range of the node number, unit number, and slot number is as follows.

Table Appendix 2.2.1-4 Allowed range of the node number, unit number, and slot number

Setting item	Allowed range		
	N-IO I/O module	FIO I/O module	
	SCSP3	SCSP3/SCSL2/SCSP2	SCSV1/SCSP1
Node number	1 to 32	1 to 14	1 to 10
Unit number	1 to 6	-	-
Slot number	1 to 2 (*1)	1 to 8	1 to 8

*1: For single configuration, only one module can be defined in a unit. Either of the slot numbers can be used.

To connect the FIO node in SCSP3/SCSP2/SCSP1/SCSV1, or connect the N-IO node by using optical ESB bus in SCSP3, set the ESB bus coupler module (SEC402/SEC401) in slot number 7 of node number 1. To connect the FIO node in SCSL2, set the ESB bus coupler module (L1EC402/L1EC401) in slot number 7 of node number 1. Because a redundant configuration is configured by two ESB bus coupler modules, an I/O module cannot be set in slot number 8.

To connect the N-IO node by using N-ESB bus in SCSP3, set the N-ESB bus coupler module (S2EN402/S2EN404) in an odd slot number of node number 1. Because a redundant configuration is configured by two N-ESB bus coupler modules, an I/O module cannot be set in the adjacent slot number (odd slot number + 1).

● Is Redundant (switching between redundant and single Input/Output module configurations)

You can specify whether or not to make the I/O module redundant. You need to specify TRUE for redundant configuration and FALSE for single configuration. Redundancy can be specified only for I/O modules that are set in odd slot numbers. Note that the adjacent slot number (the odd slot number + 1) must be left unspecified as it is used by the other I/O module in the redundant configuration.

IMPORTANT

- Start I/O Parameter Builder and check that redundant and single configurations are set correctly for the input/output module and then save the definitions. When switching between redundant and single configurations, the change is reflected in the SCS after performing offline download or online change download.
- Set the mounting positions in accordance with node numbers, unit numbers, slot numbers, and redundancy specifications so that they do not overlap. Overlaps of mounting position cause errors when building SCS projects.

■ Wiring of channels and input/output variables

Wiring is an operation where channels are associated with input/output variables. Assign one input variable or output variable to one channel.

IMPORTANT

Make sure to use input/output variables in order to access channel data from the application logic.

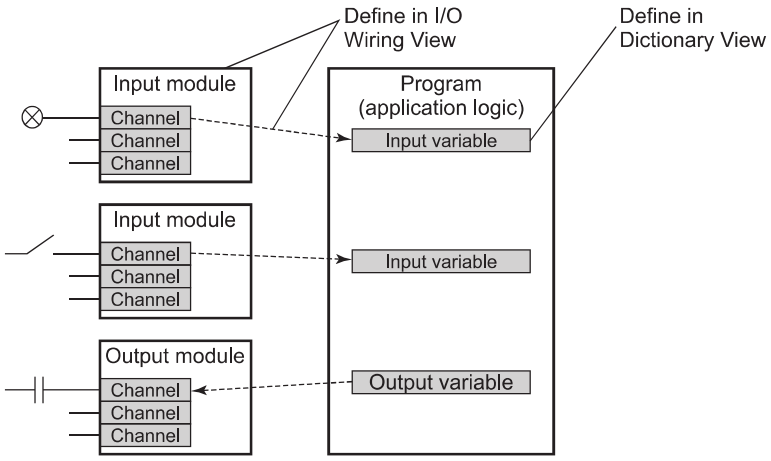

Figure Appendix 2.2.1-4 Wiring of channels and input/output variables

When you select a channel in I/O wiring tree view, a list of I/O variables that can be wired to the channel is displayed in I/O wiring grid view. Double-click the I/O variable for which you want to set the wiring, and set the wiring of channels. To assign the AO channel to S2MMM843, do not specify more than eight channels in a module.

The result of wiring is displayed in I/O Wiring Tree View. It is also displayed in the parameter setting view of each channel in I/O Parameter Builder and Dictionary View.

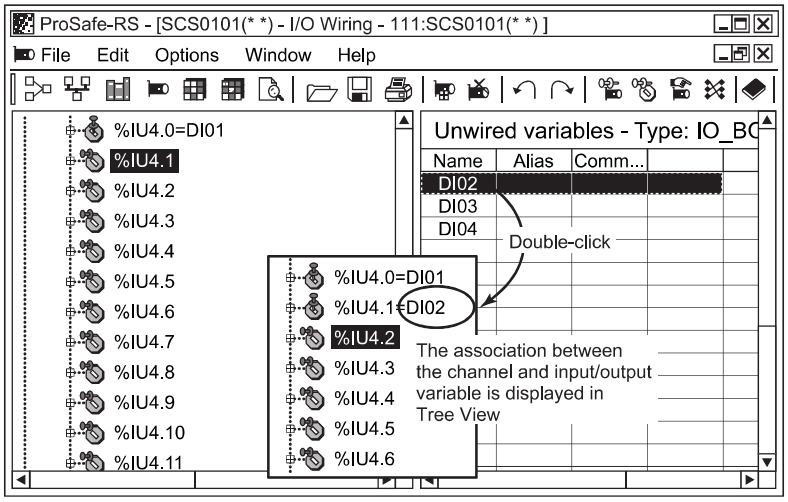

Figure Appendix 2.2.1-5 Example of wiring between a channel and input/output variable

TIP Deletion of wiring is also performed in I/O Wiring View.

In the AIO/DIO module of FIO, the signal category of the channel is determined based on the module that is used.

In the universal type I/O module, if you wire the channel and the I/O variable, the signal category of the channel is determined. If the signal category changes after re-wiring, all setting items will be initialized. If the signal category does not change even after re-wiring, the earlier setting items are retained.

Relationship between the channel and I/O variable is as follows.

Table Appendix 2.2.1-5 Relationship between the channel and I/O variable

Signal category of the channel	Type of input/output variable	Signal type (For universal type I/O modules)
AI	Type: IO_REAL Direction: Input Attribute: Read	Current input Current input (HART communication)
AO	Type: IO_REAL Direction: Output Attribute: Write or Free	Current output Current output (HART communication)
DI	Type: IO_BOOL Direction: Input Attribute: Read	Status input
DO	Type: IO_BOOL Direction: Output Attribute: Write or Free	Status output 1.3 A status output (*1) 2.0A status output (*1)

*1: You cannot select the modules mounted on the base plate for barrier.

Settings prohibited in I/O Wiring View

The following settings are not allowed in I/O Wiring View. Even if you make these settings, the operations of an SCS do not change.

- Channel filtering
  Filtering should be set as a channel parameter using I/O Parameter Builder.
- Channel mapping
  The functions provided in the Channels Map dialog box cannot be used. Even if you specify the mapping in I/O Wiring View, the setting is ignored in the SCS.
- Virtual device
  It is not allowed to switch to virtual device. If you specify a device as a virtual device in I/O Wiring View, an error occurs at building.

Appendix 2.2.2 I/O Parameter Builder

I/O Parameter Builder is used to specify parameters for input/output modules defined in I/O Wiring View.

Make the following settings in I/O Parameter Builder.

- Node parameters
- Input/output module parameters
- Channel parameters

IMPORTANT

When editing settings in I/O Parameter Builder, close I/O Wiring View first.

How to display I/O Parameter Builder

1. Select the [Engineering] launcher from the [Tools] menu of SCS Manager.
   The Engineering launcher menu appears.
2. In the Engineering launcher menu, select [I/O Parameter Builder].
   I/O Parameter Builder appears.

I/O Parameter Builder window structure

In I/O Parameter Builder, you need to set parameters for nodes or I/O modules that are selected on the I/O structure display panel. The tab sheet configuration of the workspace changes depending on the I/O module model.

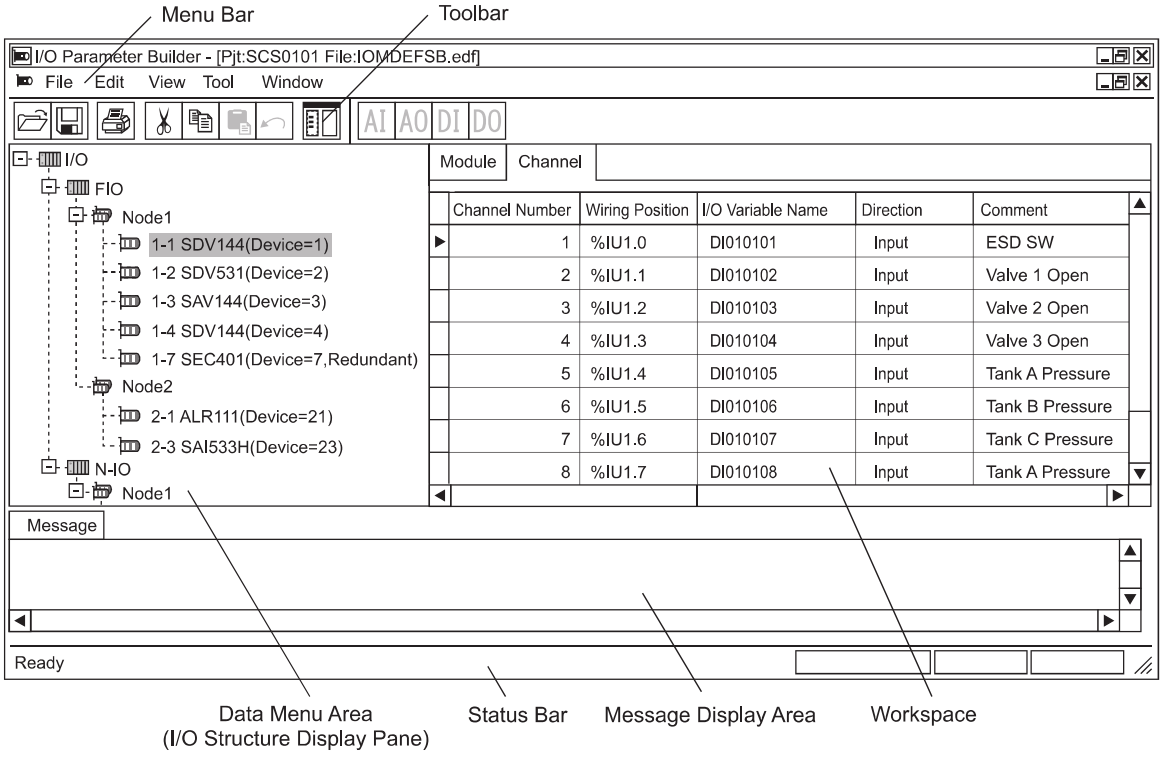

Figure Appendix 2.2.2-1 I/O Parameter Builder

Display channel switching commands in layer (indicating CPU nodes in the View menu on the menu bar)

In I/O Parameter Builder, the following menu items are displayed on the View menu of the menu bar. This is enabled only when the channel tab is selected on the workspace after selecting the universal type I/O module on the I/O structure display panel.

Table Appendix 2.2.2-1 Display channel switching commands in the View menu

Menu item	Description
AI Setting Items	Displays AI channels
AO Setting Items	Displays AO channels
DI Setting Items	Displays DI channels
DO Setting Items	Displays DO channels

AI/AO/DI/DO buttons on the toolbar

In I/O Parameter Builder, the following buttons appear on the toolbar. This is enabled only when the channel tab is selected on the workspace after selecting the universal type I/O module on the I/O structure display panel.

Table Appendix 2.2.2-2 AI/AO/DI/DO buttons on the toolbar

Button	Assigned function
AI	Same as AI Setting items of the View menu
AO	Same as AO Setting items of the View menu
DI	Same as DI Setting items of the View menu
DO	Same as DO Setting items of the View menu

Data Menu Area (I/O Structure Display panel)

The I/O structure display panel displays the I/O structure specified in I/O Wiring View. Select one target (node or input/output module) for which you want to specify a parameter from this panel. Once you select the target, the corresponding tab appears in the workspace.

The hierarchical structure of the I/O structure display panel is shown below.

Table Appendix 2.2.2-3 Hierarchy of the I/O Structure Display Panel

Layer	Description
I/O	Displayed as the top layer under which all inputs and outputs are arranged.
Type	Layer indicating types of nodes and I/O modules. FIO and N-IO are displayed. They are displayed only in SCSP3.
Node	Layer indicating the CPU node, safety node units, and N-IO nodes. Node numbers are displayed.
Module	Layer indicating I/O modules. Mounting position, I/O module models, device index, and classification of redundant and single configurations are displayed.

Workspace

In the workspace, items that can be specified for the node or I/O module selected on the I/O structure display panel are classified into separate tabs and displayed.

Table Appendix 2.2.2-4 Items displayed in the workspace

Setting target	Types of the tabs displayed	Description
Node	Node tab	Parameter setting for the node
Analog input module	Module tab	Setting of module parameters for the analog input module
	Channel tab	Setting of channel parameters for the analog input module
Analog output module	Module tab	Setting of module parameters for the analog output module
	Channel tab	Setting of channel parameters for the analog output module
Digital input module	Module tab	Setting of module parameters for the digital input module
	Channel tab	Setting of channel parameters for the digital input module
Digital output module	Module tab	Setting of module parameters for the digital output module
	Channel tab	Setting of channel parameters for the digital output module
Universal type I/O module	Module tab	Setting of module parameters for the universal type I/O modules
	Channel tab	Setting of channel parameters for the universal type I/O modules
Serial communication modules	Module tab	Settings for common parameters of serial communication modules
	Port1 tab	Settings for parameters of Port 1 of serial communication modules
	Port2 tab	Settings for parameters of Port 2 of serial communication modules
Ethernet communication module	Module tab	Settings for parameters of the Ethernet communication module
Fire and gas communication modules	Module tab	Display of parameters for fire and gas communication modules. The content set with Safety Communication I/O Editor is shown. You cannot configure the settings.

TIP

No information is displayed in the workspace even if SEC402/SEC401, L1EC402/L1EC401, or S2EN402/S2EN404 is selected on the I/O structure display panel.

Appendix 3. Precautions related to main specification additions and modifications

This section describes about the cautions and overview of important items for engineering and maintaining of specification changes and additions that were implemented in the past.

In the SCS, the operation differs with the release number. The operation is determined by the following conditions:

- The release number of the SENG software where SCS projects are newly created
- The release number of the SCS system program that is downloaded to the SCS. The SCS system program can be changed by offline downloading to the SCS.

The release number of the SENG software, where SCS projects are newly created, can be found in the SCS Project Properties dialog box. The release number of the SCS system program that is downloaded to the SCS can be found in the SCS State Management window.

Appendix 3.1 The major changes in R1

The following table shows the important contents as a compatibility information after the specification changes and additions have been implemented in R1.

Table Appendix 3.1-1 The important specification changes in R1

Release number	Revised content
R1.02	After R1.02, Variable DB is downloaded to the SCS via online change download only when variable definitions are modified. Therefore, the time and CRC of Variable DB in the work database are reflected to the master database and SCS only when variable definitions are modified.
R1.03	The item Originally Created in SCS Project Properties does not display the revision number of project data that is created by SENG with a software version prior to R1.03.
R1.03	The SCS Constants Builder displays PV Status of S_ANLG_S in SCS projects that are newly created with a software version R1.03 or later. The setting is configured to No in SCS projects that are created with a software version prior to R1.03 or earlier. The setting is configured to Yes if this SCS project is imported to the software with a version R1.03 or later.

Appendix 3.2 The major changes in R2

This section describes the important contents as a compatibility information after the specification changes and additions have been implemented in R2.

List of the important specification changes in R2

The following table shows the important contents as a compatibility information after the specification changes and additions have been implemented in R2. Detailed description is provided in the separate section, as necessary.

Table Appendix 3.2-1 The important specification changes in R2

Release number	Revised content
R2.01	Security models can be selected with the IT Security Configuration Tool.
R2.01	In the case of SCS with system program R2.01 or earlier, the operation of AIO/DIO modules stops when changes are made to I/O parameters that require IOM download. When you perform online change download after modifying such parameter settings, the output may become 0 depending on the changes made. In order to avoid shutdown in case when output is 0, measures are required at field side.
R2.02	In the case of SCS with system program R2.02 or later, the operation of AIO/DIO modules continues even if changes are made to I/O parameters that require IOM download.
R2.02	In SCS with system program before R2.02, the operation of CASE statement of ST was incorrect. When using SCS projects that are newly created by SENG before R2.02, there are precautions on when you first perform online change download after upgrading SENG.
R2.02	The checking operation in Integrity Analyzer has been changed. When using SCS projects that are newly created by SENG before R2.02, there are precautions on when you first use Integrity Analyzer after upgrading SENG.
R2.02	The self document operation has been changed. Engineering can be performed for compatibility with versions before R2.02.
R2.03	In the SCS with SCS system program R2.03 or later, the measured value for scan cycle is displayed in the SCS State Management window and SCS State Display View of CENTUM HIS. For SCS with system program R2.02 or earlier, the set scan period is displayed.
R2.03	In SCS with SCS system program R2.03 or later, the scan period for application logic execution function can be modified by online change download.
R2.03	In SCS with SCS system program R2.03 or later, the addition and deletion of I/O modules can be performed by online change download. Other items that can be modified by online change download have also been added.
R2.03	In the SCS with SCS system program R2.03 or later, you can execute automatic IOM download.
R2.03	In the SCS with SCS system program R2.03 or later, you can use the automatic scan period extension function. When using this function, use SYS_SCANEXT FB to notify the state that the scan period is extended by using the automatic scan period extension function. If the SCS projects are created by SENG R2.03 or later, you can define SYS_SCANEXT.
R2.03	In the SCS with SCS system program R2.03 or later, you can specify the SCS behavior at abnormal calculation. When using this function, use SYS_CERR FB to notify the occurrence of abnormal calculation and detect that the SCS is continuing the operation even if the abnormalities have occurred in calculation. If the SCS projects are created in SENG R2.03 or later, you can define SYS_CERR.
R2.03	With R2.03 or later, the system checks to see if there is possibility that the online change variables area in the database has been used before executing the offline download.
R2.03.59	The behaviors of inter-SCS safety communication have been changed. R2.03.59 is the official version of operations modified at R2.03.51.

Notes on online change download after upgrading SENG

In R2.02, the problem that the FB for which you have specified a minus value for a label in a CASE statement does not run properly (*1) has been fixed. Because of this, the behavior of online change downloading after you have upgraded the SENG to R2.02 will be as follows.

After you have upgraded the SENG to R2.02, if you perform a build for a project created in a version before R2.02 and execute online change downloading, all the FBs containing any CASE statement in the ST language will be downloaded (*2) even if no changes have been made to the logic. Once you rebuild a project of a version earlier than R2.02 on a R2.02 system and execute online change downloading, FBs with no logic change will not be downloaded in the subsequent online change downloading.

You can use the Database Validity Check Tool, as necessary, to find out which FBs will be downloaded before you execute online change downloading.

In a revision before R2.02, FBs containing any CASE statement in which a minus value is specified for a label do not run correctly, so they can be spotted and removed in the system test. Therefore, no such FBs should exist in a project. However, if such FBs do exist, the FBs may start to run normally after downloading.

To avoid such unexpected change in behavior, you should check the project to see if there are any FBs containing a CASE statement in which a minus value is specified for a label.

- If any FBs using a minus value for a label of CASE statement are found, make sure that the change in behavior does not cause any adverse effects on the system. (*3)(*4)
- If FBs using a minus value for a label of CASE statement are not found, all the FBs using CASE statements will be downloaded but the system behavior remains the same; so you do not need to perform tests again.

*1: If you specify a minus value for a label in a CASE statement in ST, an incorrect database which causes unexpected behavior may be generated. In the following example, if variable1 is neither “1” nor “2”, “3” is always assigned to aaa.

```
CASE variable1 OF
1: aaa := 1;
2: aaa := 2;
-1: aaa := 3; (* When the variable1 is neither 1 nor 2, this line is always executed.*)
-2: aaa := 4;
ELSE aaa := 5;
END_CASE;
```

*2: In this case, Cross Reference Analyzer does not detect the difference of the FBs using CASE statements.
*3: In this case, Cross Reference Analyzer does not detect the difference of the FBs using a minus value for a label of CASE statement.
*4: To find the locations where CASE statements are used, open multiple STs in Multi-Language Editor and search for “CASE”.

Behavior of AIO/DIO modules at online change download

If you perform online change download after using I/O Parameter Builder to modify setting items that require IOM download, AIO/DIO modules continue to operate in SCS system program R2.02 or later. However, it stops operation with versions earlier than R2.02.

IMPORTANT

If AIO/DIO module stops operation, a message appears notifying the possible occurrence of IOM Fail before starting the online download.

You can confirm the system program release number of SCS in the SCS State Management Window of the SCS maintenance support tool.

This section explains the behaviors of AIO/DIO modules when the SCS system program revision is earlier than R2.02.

Behavior of Input modules

- At the time of online change, the data status of all channels of the target module become BAD, and the diagnostic information message “IOM Fail” appears. The input signals of all channels of the module are processed according to the [Input Processing at Fault] settings.
- If on-demand HART communication with PRM is performed, the HART communication is discontinued during the “IOM Fail” status.
- On completion of online change download, the channels’ data automatically return to the values input to the channels and all data statuses become GOOD.
- A diagnostic information message indicating that the input module has recovered to normal is output.
- For dual-redundantly configured I/O modules, the odd-numbered module takes the control right.

TIP

If any setting items that require IOM download and the setting of [Input Processing at Fault] or [Input Value at Fault] are changed online simultaneously, the input value will conform to the changed settings of [Input Processing at Fault] and [Input Value at Fault].

Behavior of Output modules

- At the time of online change, the data status of all channels of the target module become BAD, and the diagnostic information message “IOM Fail” appears. The output values on all channels change to 0 if the target module is a digital output module, and change to the tight-shut output values (*1)if the target module is an analog output module.
- If on-demand HART communication with PRM is performed, the HART communication is discontinued during the “IOM Fail” status.
- On completion of online change download, the data status of all channels become GOOD, while the output values still remain 0 with a digital output module or tight-shut output values with an analog output module.
- A diagnostic information message indicating that the output module has recovered to normal is output.
- For dual-redundantly configured output modules, the odd-numbered module takes the control right.
- If the user performs the output enable operation, outputs of the application logic are output from the output module.

*1: A tight-shut output value can be set for each channel using the I/O Parameter Builder.

Possibilities of online change download

The online change downloadable information for the SCS with a system program before R2.03 is as follows:

POU information that is changeable online

There are changes that enables you to execute online change download or offline download according to each POU type.

Table Appendix 3.2-2 POU information

Modification	Online Change (*1)		
	Program	User-Defined FB	User-Defined FU
Adding/deleting variables	Yes	Yes (*2)	Yes (*3)
Adding a variable to be named the same as that of a deleted variable	No	No	No
Changing attributes of variables	No	No	No
Adding/deleting I/O variables	Yes	-	-
Adding/deleting FU	Yes	Yes	Yes
Adding/deleting user-defined FU (*4)	Yes	Yes	Yes
Adding/deleting FB instances	Yes	No	-
Adding/deleting the user-defined FB instances (*4)	Yes	No	-
Adding a FB to be named the same Instance as that of a deleted FB	No	-	-
Changing logic	Yes	Yes (*2)	Yes (*2)
Creating/deleting programs Changing program names	No (*5)		
Creating/deleting user-defined Function Blocks Changing user-defined Function Block names	No (*5)		
Creating/deleting user-defined Functions Changing user-defined Function names	No (*5)		

*1: Yes: Changeable by online change download.
No: Offline download is required.
*2: It is not allowed to increase/decrease parameter values or change attributes. They cause an error when the database is downloaded.
*3: An error occurs during downloading.
*4: When user-defined FU/FB are added, they need to be tested. Pre-validated user-defined FU/FB do not need to be tested.
*5: Online change is only possible for local variables.

I/O module information that is changeable online

The following table shows whether each item of I/O module related information can be changed by online change downloading.

Table Appendix 3.2-3 I/O module information

Modification	Online Change (*1)
Adding nodes	No
Deleting nodes	No
Changing parameters of nodes	Yes
Adding I/O modules	No
Deleting I/O modules	No
Changing redundant I/O modules	No
Changing parameters of I/O modules	Yes
Changing parameters of channels	Yes
Changing subsystem communication definitions	Yes
Defining link between a variable and an idle channel	Yes
Deleting link between a channel and a variable	Yes
Changing link between a channel and a variable	Yes

Continues on the next page

Table Appendix 3.2-3 I/O module information (Table continued)

Modification	Online Change (*1)
Adding, changing or deleting subsystem communication definitions	Yes
Changing wiring of communication input/output FBs	Yes

*1: Yes: Changeable by online change download.
No: Offline download is required.

Constants and network information that are changeable online

The following table shows whether the setting can be changed by online change downloading in the constant and network related items.

Table Appendix 3.2-4 Constants and Network

Classification	Modification	Online Change (*1)
Configuration	Name	No
	Password	No (*2)
Resource	Name	No
	Resource Number	No
	Scan period	No
	Number of variables permitted for online	No
	Size of temporary variables and constants area	No
Network	IP address	No
	Station address	No
	Inter-SCS safety Communication (Binding)	No
Optional ESB BUS Repeater	Optional ESB BUS Repeater	No
	Max. extension distance	No

*1: No: Offline download is required.
*2: Setting and changing passwords is ignored.

Builder definitions that are changeable online

The following table shows whether online change downloading is possible after you have changed definitions using builders.

Table Appendix 3.2-5 Online change download

Builders	Online Change (*1)
SCS Constants Builder	No
I/O Parameter Builder	Yes
Communication I/O Builder	Yes
SCS Link Transmission Builder	Yes
Modbus Address Builder	Yes
Tag Name Builder	Yes
Alarm Priority Builder	No
Alarm Processing Table Builder	No

*1: Yes: Changeable by online change download.
No: Offline download is required.

Behaviors at abnormal calculation in application logic

If abnormal calculation occurs in the application logic of an SCS with a system program before R2.03, the SCS stops.

About behaviors of SCS at abnormal calculation

- If an overflow or division by zero occurs in operations with REAL-type variables, or division by zero in operations with integer-type variables, SCS stops.
- When floating-point data is converted to a DINT number by the ANY_TO_DINT function, if the resultant number exceeds the maximum or falls below the minimum integer values (i.e. overflow occurs), the SCS stops.
- For the input to ANY_TO_TIME, use a DINT type value in the range from 0 to 86400000. If a value beyond this range is used, it cannot return a proper time. Note that when a real number value greater than 4294967295 (the maximum number of the unsigned 32-bit integer) or smaller than -2147483648 (the minimum number of the unsigned 32-bit integer) is used, the SCS stops.
- If access to the outside of an array occurs, the SCS stops.

Enhanced checking by Integrity Analyzer

Checking for multiple writing to the same variable

Multiple writing to the same variable can reduce the program readability and end up downloading of programs that cause unintended behavior. Integrity Analyzer in R2.02 detects multiple writing to the same variable and displays a warning message.

This warning message is not output with the revisions before R2.02, but it will be displayed after you have upgraded to R2.02 when the program contains any multiple writing to the same variable. If this warning message is displayed, examine the program to find out if you can eliminate the multiple writing.

If you find that the multiple writing is necessary, acknowledge the results of analysis in Integrity Analyzer and you can download the program to SCS without change. In this case, the program can be used as a function allowed for safety application after verifying its validity in user tests.

Checking for multiple calls to the same FB instance

Multiple calls to the same function block (FB) instance can lead to an unexpected state in the system and the program may not behave as intended. Integrity Analyzer in R2.02 detects multiple calls to the same FB instance and displays a warning message.

This warning message is not output with the revisions before R2.02, but it will be displayed after you have upgraded to R2.02 when the program contains multiple calls to the same FB instance. If this warning message is displayed, examine the program to find out if you can eliminate the multiple calls. If you find that the multiple calls are necessary, acknowledge the results of analysis in Integrity Analyzer and you can download the program to SCS without change. In this case, the program can be used as a function allowed for safety application after verifying its validity in user tests.

Checking for writing to output variable status

I/O variable statuses (.status) are the data that reflect the actual statuses (normal/abnormal) of I/O channels. Therefore, they should not be changed by user logic. Integrity Analyzer in R2.02 detects writing to output variable statuses and raises an error.

In revisions before R2.02, no such error is raised. But this error will be raised after you have upgraded to R2.02 when there is any program that writes to any output variable status. If an

error message is displayed, change the program to eliminate the writing to output variable statuses.

Specification changes made in SCS system program (Release number R2.03.51)

Overview of specification changes

After the SCS system program release number R2.03.51, information on system time is no longer used to diagnose delay in inter-SCS safety communication and SCS link transmission safety communication. Specifically, there is no need to consider the gap in the system times of related SCSs when determining the DLYT value.

IMPORTANT

In order to operate inter-SCS safety communication and SCS link transmission safety communication with the specification of R2.03.51 or later, upgrade the revision of all SCS system programs that communicate each other to R2.03.51 or later. If either the revision of the transmission or reception side has not been upgraded, the system operates with the method before the change, which uses the system time for diagnosis of delay. If the communication is performed with the method before the change, take the gap in the system times among involved SCSs as the DLYT value as in the past.

Calculation method of DLYT in Inter- SCS safety communication

How to calculate DLYT in inter-SCS safety communication in case of revisions earlier than R2.03.51 is explained below.

Reception interval timeout value (OUTT) and inter-FB transmission delay timeout value (DLYT) are used to set the timeout monitoring time of inter-SCS safety communication.

Temporary transmission delay errors can be detected by monitoring the communication with OUTT. In addition, you can set DLYT to detect constant transmission delay errors.

DLYT detects not only transmission delay but also time gap among SCSs. For this reason, determine the set value of DLYT taking generation of erroneous trips due to time gap into consideration as well.

- Reception interval timeout value (OUTT)
  An FB for communication on the consumer side (CONS_*) checks the interval of data reception. If the data reception interval exceeds the reception interval timeout value (OUTT), a communication error occurs and a failsafe value (VAL) is output.
- Transmission delay timeout value (DLYT)
  DLYT checks the time from the time an FB for communication on the producer side (PROD_*) transmits data to the time an FB for communication on the consumer side (CONS_*) receives the data. This time interval is called inter-FB transmission delay time. If the status where this interval exceeds the inter-FB transmission delay timeout value (DLYT) of CONS_* continues for the time indicated by OUTT, a communication error occurs and a failsafe value (VAL) is output.

The guidelines of timeout value settings are given in the following.

- Setting of Reception Interval Timeout Value (OUTT)

  OUTT=(select the longer scan period of either the producer or the consumer) x 8 + (Additional Delay)

  Additional Delay

  V net Delay

  No BCV/CGW used: 0 s
  Via BCV/CGW: the number of BCV used x 1 s +
  the number of pairs of CGWs used x 2 s

  Vnet/IP Delay

  Within a Vnet/IP domain: 0 s

  Between Vnet/IP domains (No wide area network):
  0 s (Regardless of the number of L3SWes)

  Between Vnet/IP domains (Wide area network):
  1 s (Regardless of the number of L3SWes)

  Vnet/IP – V net: V net delay + Vnet/IP delay + V net router delay (1 s)

  V net(1) –Vnet/IP –V net(2): V net(1) delay +Vnet/IP delay + V net(2) delay +
  Two V net routers' delay (2 s)

  Set 3 seconds to OUTT when the calculated OUTT is shorter than 3 seconds.

- Setting of the Transmission Delay Timeout Value (DLYT)

  1. In cases of Inter-SCS safety communications between:
     - SCSs in the same domain
     - SCSs synchronized with GPS time
     - SCSPs synchronized with a Vnet/IP network time
     - An SCSP synchronized with SNTP server and an SCSV synchronized with GPS time:

     DLYT= (scan period of the producer) + (scan period of the consumer) + (Additional Delay)
     Additional Delay

     V net Delay

     No BCV/CGW used: 300 ms
     Via BCV/CGW: the number of BCV used x 1.3 s +
     the number of pairs of CGWs used x 2.3 s

     Vnet/IP Delay
     Within a Vnet/IP domain: 300 ms
     Between Vnet/IP domains (No wide area network):
     300 ms (Regardless of the number of L3SWes)
     Between Vnet/IP domains (Wide area network):
     1.3 s (Regardless of the number of L3SWes)
     Vnet/IP – V net: V net delay + Vnet/IP delay + V net router delay (1.3 s)
     V net(1) – Vnet/IP – V net(2): V net(1) delay + Vnet/IP delay + V net(2) delay +
     Two V net routers' delay (2.6 s)

     Set 3 seconds to DLYT when the calculated DLYT is shorter than 3 seconds.

  2. In case of Inter-SCS safety communications between SCSs synchronized with V net time in SCS in different domains:
     DLYT= (the number of BCV used) x 5 s

  3. If there are V net routers between SCSs synchronized with V net time in the Inter-SCS safety communications,
     DLYT= (BCV/number of V net router layers) x 5 s

IMPORTANT

If you set 0 seconds to DLYT and bypass inter-FB transmission check, it is not possible to use reception data of the given inter-SCS safety communication for the safety purpose.

- In both cases, set the value of OUTT as the DLYT value if OUTT is smaller than DLYT.
- The timeout value is used for calculating system reaction time.

Precautions when setting DLYT for Inter- SCS safety communication

Precautions to be followed when setting DLYT for inter-SCS safety communication in software versions R2.03.51 or earlier are given below.

- If IRIG-B time synchronization method is selected, be sure to take the time gap due to failure of GPS and IRIG-B interface into consideration.
- In the case of SCSs connected to Vnet/IP, time gap due to the SNTP server must be taken into consideration.
- Unify the time synchronization method among SCSs that perform inter- SCS safety communication and determine the setting value such that erroneous trips do not occur due to time gap among SCSs.

  If you set DLYT among SCSs over multiple domains, the following points must also be taken into consideration.
- If V net time synchronization method is selected, delay of up to 5 seconds in the first level of BCV-V and 10 seconds in the second level may occur. It is recommended to select IRIG-B time synchronization if it is found that the gap is outside the allowable range.
- If domains are connected via a gateway for broadband connection, it is recommended to synchronize V net time of each domain within the allowable range or select IRIG-B time synchronization.

Precautions when setting DLYT for SCS link transmission safety communication

How to calculate DLYT of SCS link transmission safety communication for revisions R2.03.51 or earlier is explained below.

Reception interval timeout value (reception timeout, hereinafter referred to as OUTT) and inter-SCS transmission delay timeout value (transmission timeout, hereinafter refer red to as DLYT) are used to set the timeout monitoring time of SCS link transmission safety communication.

Temporary transmission delay errors can be detected by monitoring the communication with OUTT. In addition, you can set DLYT to detect constant transmission delay errors.

DLYT detects not only transmission delay but also time gap among SCSs. For this reason, determine the set value of DLYT taking generation of erroneous trips due to time gap into consideration as well.

- Reception interval timeout value (OUTT)
  It is valid only when the station on the transmission side is an SCS.

  The reception interval refers to the time interval of receiving data by an SCS. Specify the reception interval timeout value (OUTT) for each communication target. If normal data cannot be received within the reception interval timeout value (OUTT), a communication error occurs and a failsafe value is output.
- Inter-SCS transmission delay timeout value (DLYT)
  It is valid only when the station on the transmission side is an SCS.

Inter-SCS transmission delay time is the time duration from the time an SCS on the transmission side sends data to the time an SCS on the reception side receives the data. If the inter-SCS transmission delay timeout value exceeds the DLYT timeout value and the status continue for the time specified by OUTT or longer, a communication error occurs and a failsafe value is output.

The guidelines of timeout value settings are given in the following.

- Setting of reception interval timeout value (OUTT)
  OUTT = (Scan frequency on the transmission or reception side, whichever longer) X~ 8

  If OUTT is 3 seconds or less, set 3 seconds.

- Guidelines of setting value of transmission delay timeout value (DLYT)
  If the time synchronization method employed is V net time synchronization or Vnet/IP time synchronization, set 3 seconds for DLYT.

  In the case of IRIG-B time synchronization, determine DLYT as follows:

  DLYT = (Scan frequency on transmission side) + (Scan frequency on the reception side) + (Delay addition) + (Time gap addition)

  Delay addition: 100 ms

  Time gap addition: Determine the setting value so that erroneous trips do not occur due to time gap.

  If DLYT is 3 seconds or less, set 3 seconds.

  If 0 seconds are set for DLYT, checking of transmission delay by DLYT is bypassed.

Appendix 3.3 The major changes in R3

This section describes the important contents as a compatibility information after the specification changes and additions have been implemented in R3. Detailed description is provided, as necessary.

List of the important specification changes in R3

The following table shows the important contents as a compatibility information after the specification changes and additions have been implemented in R3. Detailed description is provided in the separate section, as necessary.

Table Appendix 3.3-1 The important specification changes in R3

Release number	Revised content
R3.01	The specifications for the operation of the ANLG1OO2D, ANLGVOTER, ANLG_S, ANLGI, and VEL functions blocks have been modified.
R3.02	In the SCS with SCS system program R3.02 or later, you can use the IOM reset function. To use the IOM reset function, execute IOM download from the IOM download tool.
R3.02	IT security is strengthened in SOE OPC server R3.02 or later.
R3.02	When using ALE111 in order to perform Modbus slave communication via Modbus TCP protocol, you must use the style S1 module with unit revision U:2 or later.
R3.02	For SCS projects created by SENG before R3.02.00, the POU related online change download may be enabled when Clean project is performed.
R3.02.10	In SCS Constants Builder, the definition item name Writing to a Single Holding Register has been changed to 16-bit Modbus master support mode.

Function Block parameters

The function block operation specifications have been changed in the SCS system program release number R3.01.

Support for Analog Input modules for Thermocouple/RTD

In revisions earlier than R3.01, the following function blocks were able to handle normalization data from 0 to 100% only with their parameters.

Table Appendix 3.3-2 Function Blocks whose parameters were changed in R3.01

Function block	Parameter
ANLG1OO2D	IN1, IN2, DEL, VAL, OUT
ANLGVOTER	IN1, IN2, IN3, DEL, VAL, OUT
ANLG_S	IN, HYS
ANLGI	IN, HYS
VEL	IN, VL, HYS

ANLG1OO2D

Due to the specification changes of ANLG1OO2D parameters, the operations of VAL on SCS are changed as shown in the following table.

Table Appendix 3.3-3 Specification of VAL

Earlier than R3.01	R3.01 or later
-25 to 125%. If you specify a value smaller than -25.0%, it is processed as -25.0%. If you specify a value greater than 125%, it is processed as 125 %.	Specify as % or engineering units. (No restrictions on range in VAL.)

ANLGVOTER

Due to the specification changes of ANLGVOTER parameters, the operations of VAL on SCS are changed as shown in the following table.

Table Appendix 3.3-4 Specification of VAL

Earlier than R3.01	R3.01 or later
-25 to 125%. If you specify a value smaller than -25.0%, it is processed as -25.0%. If you specify a value greater than 125%, it is processed as 125 %.	Specify as % or engineering units. (No restrictions on range in VAL.)

Specification of SCS constant "Writing to a Single Holding Register" has been changed in R3.02.10

"Writing to a Single Holding Register" is a setting item of SCS Constants Builder that was added in R3.02.00. In R3.02.10, the specification of this setting item has been changed as follows:

- The item name has been changed from "Writing to a Single Holding Register" to "16-bit Modbus master support mode".
- When "16-bit Modbus master support mode" is set to Disable, there is no difference in the behavior between R3.02.00 and R3.02.10.
- The following table describes the behaviors when the SCS system program release number is R3.02.00 and when the SCS system program release number is R3.02.10 with "16-bit Modbus master support mode" set to Enable. There is no difference in writing to a Preset Single Register between R3.02.00 and R3.02.10.

Table Appendix 3.3-5 SCS system program release number and the behavior when "16-bit Modbus master support mode" is set to "Enable"

SCS system program release number	Behavior when "16-bit Modbus master support mode" is set to "Enable"
R3.02.00 (*1)	• Preset Single Register (function code 06) is available. • If a multiple-register read/write command (function code 03, 04, or 16) is used specifying an even number for the beginning reference number or an odd number for the size of data, the error code 10 or 11 (hex.) is returned.
R3.02.10	• Preset Single Register (function code 06) is available. • Data access is possible by using multiple-register read/write commands (function codes 03, 04, and 16) specifying an even number for the beginning reference number and/or an odd number for the size of data. Error code 10 or 11 (hex.) is not returned even if an even number is specified for the beginning reference number or an odd number is specified for the size of data.

*1: This means the case when the version of SENG is R3.02.00 and the case when SENG is upgraded to R3.02.10 but offline downloading to SCS is not yet performed.

Appendix 3.4 Major changes in R4

This section describes important contents as compatibility information after the specification changes and additions implemented for R4. Detailed descriptions are provided as necessary.

List of important specification changes in R4

The following table shows important contents as compatibility information after the specification changes and additions implemented for R4. Detailed descriptions are provided in separate sections as necessary.

Table Appendix 3.4-1 Important specification changes in R4

Release number	Revised content
R4.01	Engineering using AD Suite has been enabled.
R4.02	Engineering using iDefine when selecting I/O list engineering has been enabled.
R4.03.10	With SCS projects for which I/O list engineering has been selected, engineering for communication I/O has been modified to be implemented with Safety Communication I/O Editor instead of with Communication I/O Builder.
R4.05	The values available for the "SW" data item are changed to 0, 1, and 2 in each MOA, MOB_11, MOB_21 FB mapping block. As compatibility information, the previous specifications before the system is upgraded to R4.05 are described as follows: • The values available for the SW are 0 and 1. • The value of the FB's SW parameter is reflected as is to the data item SW.
R4.06	Settings to check-in and check-out automatically have been added to the Safety I/O Editor, etc., of AD Organizer.
	The specifications of the iDefine-config file has been changed. To engineer by using iDefine, upgrade the SCS project to the latest version and use it with the recommended version number of iDefine.
R4.07	The classification of POWE/LOGE functions has been changed. POWE/LOGE is a safety function for new SCS projects that are created in SENG in R4.07.00 or later. It can be used as an input to safety loops. It remains as an interference-free function for new SCS projects that are created in SENG in revisions earlier than R4.07.00. It cannot be used as an input to safety loops.
R4.08	The range of reference numbers of Modbus devices is expanded. The range of reference numbers of Modbus devices is expanded for new SCS projects that are created in SENG in R4.08.00 or later. The applicable SCSs are SCSP1/SCSU1/SCSP3/SCSL2. The range of reference numbers of Modbus devices is not expanded for new SCS projects that are created in SENG in revisions earlier than R4.08.00. As compatibility information, the specifications for revisions earlier than R4.08.00 are described. • Coil: 00001 to 01000 • Input relay: 10001 to 14000 • Input registers: 30001 to 34000 • Holding registers: 40001 to 41000
R4.09	The specifications of online change download of POU has changed. For SCS projects newly created with SENG R4.09.00 or later, online change download is available when newly creating, deleting, or renaming all program, user-defined function, and user-defined function block POUs. For SCS projects newly created with SENG earlier than R4.09.00, among all POUs, online change download is available for changes of program name only.
	ProSafe-RS R4.09 or later does not support iDefine. You can use iDefine if you use ProSafe-RS R4.02 to R4.08.
R4.10	The following diagnostic information notification system function blocks have been added: SYS_CPUDSP, SYS_NODEPSU, SYS_N_NODEPSU

Communication I/O List Output Tool

Communication I/O List Output Tool is a tool for creating a safety communication I/O list based on the information of %W included in an SCS project created upon selecting I/O list engineering with a version between R4.01 through R4.03.00. %W is defined as information on communication I/O definitions and communication I/O wiring by using Communication I/O Builder.

When this tool creates a safety communication I/O list, the information of Dictionary View and I/O Wiring View is referenced as well.

The following packages are required to run this tool:

- RS4E5100 safety system engineering and maintenance function
- RS4E5210 I/O list engineering package

Also note that this tool can only be used by users that belong to the PSF_MAINTENANCE group.

Using Communication I/O List Output Tool

In R4.03.10 or later, when performing communication I/O related engineering with an SCS project for which I/O list engineering has been selected, use Safety Communication I/O Editor started from AD Organizer. Communication I/O Builder will be used as read-only.

When you change the communication I/O-related engineering data of an SCS project that was created with a software version from R4.01 through R4.03.00, create a safety communication I/O list by using this tool and load it into Safety Communication I/O Editor.

IMPORTANT

When the engineering is performed by using iDefine, follow these steps after upgrading the software:

1. Create a safety communication I/O list by using this tool, and import it to an empty safety communication I/O list.
2. Among the data defined in the Client I/O table of iDefine, enter the data to be mapped to the user-defined columns of Safety Communication I/O Editor to the the user-defined columns of Safety Communication I/O Editor.
   If you import the ProSafe-RS I/O file to iDefine without performing this task, the corresponding data in the Client I/O table of iDefine will be lost.

   This is because, in the safety communication I/O list created with this tool, user-defined columns are empty.
3. Run Export to iDefine.
4. Import the ProSafe-RS I/O file to iDefine.

Creating a safety communication I/O list

A list cannot be created if the SCS project for which the safety communication I/O list is being created is in use. Close SCS Manager of the applicable SCS project.

1. Click `(ProSafe-RS installation folder)\YOKOGAWA\eng\Tool\RHECIOOutput4310.exe`. The following dialog box appears.

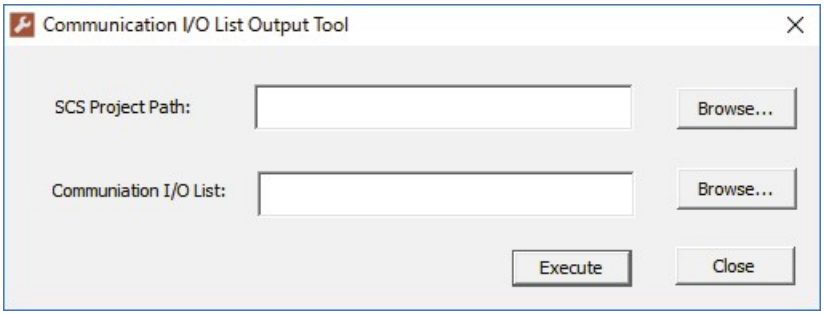

Figure Appendix 3.4-1 Communication I/O List Output Tool screen

2. In the text box for SCS Project Path, specify the path of the SCS project for which the safety communication I/O list is being created. You can also select the path of the SCS project by clicking [Browse].
3. In the text box for Communication I/O List, specify the file name of the safety communication I/O list in the xlsx format of Microsoft Excel. Specify the path where the safety communication I/O list is to be generated by clicking [Browse].
4. Click [Execute].
   The safety communication I/O list is generated in the specified folder.

● Format of data included in the safety communication I/O list

When the safety communication I/O list is generated, the SCS project name is added to the beginning of the P&ID Tag, Program Group, and Communication Group.

Example) If the SCS project name is SCS0101 and the Communication Group is C001, the Communication Group in the list becomes SCS0101_C001.

For this reason, the safety communication I/O lists of multiple SCS projects included in the same AD project can be loaded in order in Safety Communication I/O Editor of the same AD project.

■ Online change of POU information

The availability of online change download to SCS for an SCS project created with SENG earlier than R4.09.00 or when clean project is not executed for an SCS project earlier than R4.09.00 is as follows.

● Changing POU

The following table shows whether POU can be changed online: for operations on POU, online change download can be used for changes of Program name only. If you try to perform online download change on the item that No is described in the table, an error is notified at the time of online change download.

Table Appendix 3.4-2 Whether or not online change can be used for POU operations

Type of POU	Changing a name	Creating, deleting
Program	Yes	No
User-defined FU	No	No
User-defined FB	No	No

Since a new program can not be created online, we recommend that you create dummy programs in advance and change the name of the program online as you need.

Changing a library

When a library is added to or deleted from SCS project, offline download is needed. A warning is displayed at the build operation, and an error occurs at online change download operations.

A project that is created with the revision earlier than R3.02.00 will be in the same condition as R3.02.00 when clean project is executed. Therefore, you cannot perform online change download when the library is added or deleted.

Appendix 4. Maintenance of sales discontinued products

This section describes information that is essential for maintenance of "sales discontinued products".

Appendix 4.1 Time synchronization of SCSV1

SCSV1 is connected on V net. This section describes the specifications and precautions related to the time synchronization of SCSV1.

Time synchronization methods for SCSs connected to V net

There are the following two time synchronization methods, from which the user can select the more appropriate one for the given application.

Table Appendix 4.1-1 Time synchronization method

Method	Description	Setting method
Synchronization with V net time (standard)	Uses the mechanism for synchronizing time of each station connected to V net.	Select "V net" as the time synchronization method in SCS Constants Builder. (*1)
IRIG-B time synchronization (optional)	Uses the GPS unit as the standard time server. If this output (IRIG-B) is connected to each SCS, the standard time (date, hour, minute, second) and the synchronization timing are distributed. Each SCS is synchronized with this timing. Since GPS is used, it is possible to acquire events with high time accuracy.	Connect a commercially available GPS unit and a connector on the CPU node with IRIG-B. Select "IRIG-B" as the time synchronization method in SCS Constants Builder.

*1: The standard time is specified by the user using SCS Maintenance Support Tool of the SENG or the Adjust Time dialog box of an HIS.

Synchronization with V net time

When synchronization with V net time is applied, the user can set the time using SCS Maintenance Support Tool of the SENG or the Adjust Time dialog box of an HIS.

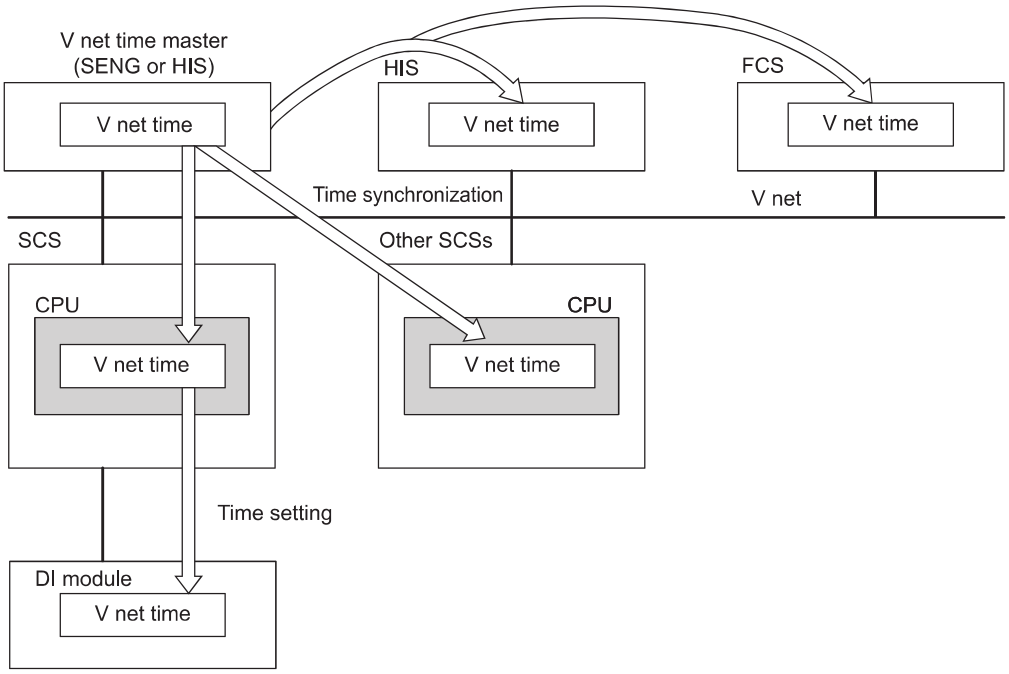

Figure Appendix 4.1-1 Synchronization with V net time

TIP

If the diagnostic information message, "GPS Interface Unit Error" is notified when synchronization with V net time, the CPU module need not be replaced if the following conditions are met. Since this message does not present any problem in practical operations or on safety, you can continue to operate the system.

- If the message is generated only on the control-side CPU module in the redundant configuration immediately after completion of APC:
  If the recovery message, "GPS Interface Unit Recover" is displayed for the control-side CPU module immediately thereafter, the module is not faulty.
- If the V net configuration is unstable:
  In a condition where the V net is not connected correctly, such as at startup, a bus configuration error may occur. In this case, the V net controller in CPU module cannot read time information and this message will be notified as a result. Reconnect the bus correctly and start the SCS. If the message no longer appears, the module is recovered.

IRIG-B time synchronization

In IRIG-B time synchronization, the time is acquired from the standard time receiver. The IRIG-B time is used for time stamps of events and alarms set in the CPU. This method produces more accurate timing for events among SCSs, compared to synchronization with V net time. The time of the CPU module and DI modules are synchronized to the IRIG-B time.

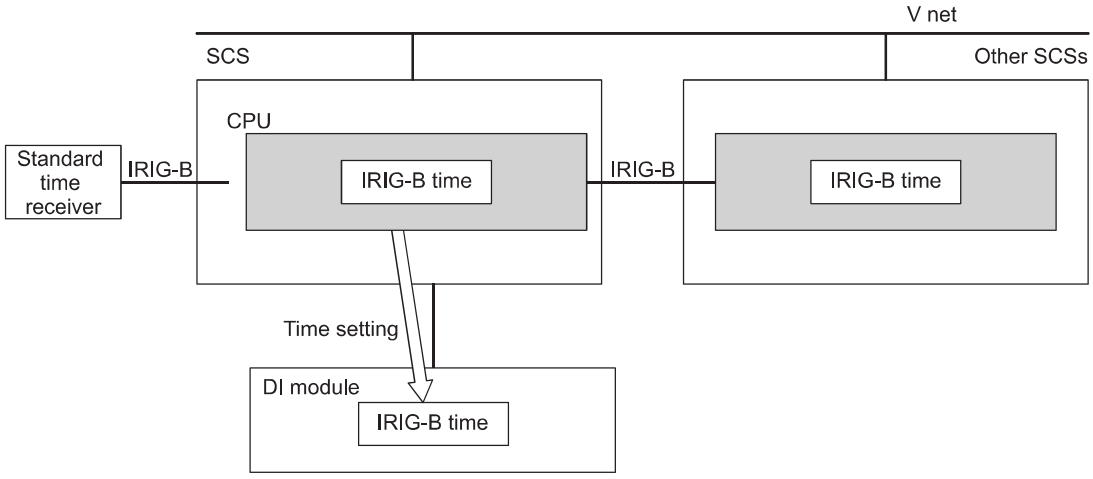

Figure Appendix 4.1-2 IRIG-B time synchronization

Precautions for time synchronization

Precautions regarding time synchronization of SCSs that are connected on V net are described as follows:

When the V net time synchronization is selected

Changing the V net time may cause the SOE generation order to be reversed. Be sure to take the timing to set the time and the difference of the time into consideration when setting the V net time.

When the IRIG-B time synchronization is selected

- It is necessary to synchronize V net clock with IRIG-B clock.
- If the input of the IRIG-B signal fails, SCS updates the time based on the IRIG-B time immediately before the failure. (No synchronization with V net time)
- When the input of the IRIG-B signal recovers, the displayed time may be set back to synchronize with the IRIG-B time again. In this is case, if you want to check the messages and events raised before the recovery, do not sort the messages and events until you finish your check.

If a Vnet/IP domain and a V net domain are connected via a V net router

The following precautions apply in a situation where a V net domain and a Vnet/IP domain are connected via a V net router and the V net time synchronization and the Vnet/IP time synchronization are selected as their respective time synchronization methods.

- If you are using a V net router of style S3 and above and have enabled the Transfer system time ([Transfer higher] or [Transfer lower]) in the V net router property of System View for CENTUM VP R5.01 or later, it is not possible to change the time from a SENG in the domain to which the time is transferred.
- If you are using a V net router of a style below S3 and have enabled the [Transfer lower] of Transfer system time ([Transfer System Time - Transfer lower] for CENTUM VP earlier than R5.01), it is not possible to change the time from a SENG in the V net domain that constitutes a lower domain.

Time discrepancy when multiple domains are connected

You need to consider the following points when connecting multiple domains:

- The time discrepancy that occurs between each connected domain depends on the number of connected BCV-V units. The discrepancy is a maximum of 5 seconds for the first level BCV-V and a maximum of 10 seconds for the second level. Estimate these deviations and if they are not acceptable, consider applying IRIG-B time synchronization.
- If a domain is connected through the wide area network gateway units (CGW), you need to take the measure to keep the differences of the V net time among the domains within an allowable range. Alternatively, consider applying IRIG-B time synchronization.

Actions taken at error occurrence in IRIG-B time synchronization

The IRIG-B time synchronization status can be checked in the SCS State Management Window of the SCS Maintenance Support Tool on the SENG, or in the SCS Status Display view on the HIS.

Reasons for time synchronization error

A time synchronization error occurs for the following reasons.

- Disconnected IRIG-B cable connector
- IRIG-B interface unit failure in the SCS
- No time notification due to GPS receiver failure

TIP

Examples of GPS receiver failure are listed below.

- Failure in the communication route from the GPS antenna to the GPS receiver
- Antenna failure or receiving problem

What happens when the GPS receiver fails is determined by the specification of the selected GPS receiver. The following is an example of what might happen when the GPS receiver fails.

- Since GPS signals are no longer received, the GPS receiver operates based on its clock.
- If reception problem continues more than a specified period, the GPS receiver stops operating on its clock and also stops notifying time information to the connected devices.

Once time notification is stopped, the SCS outputs a diagnostic information message notifying an IRIG-B error.

Notification of time synchronization error

- If the IRIG-B time synchronization state has become abnormal when the IRIG-B time synchronization is selected, the SYNC LED on the SCS's CPU module turns off and a diag-

nostic information message indicating an error is notified. If the SCS adopts a redundant CPU module configuration, diagnostic information messages regarding both modules are notified.

- Once the IRIG-B time synchronization state returns to normal, a diagnostic information message indicating a recovery is notified.

SCS actions taken upon time synchronization error

If time synchronization with IRIG-B stops, the SCS does not synchronize with the V net time. Instead, the SCS's CPU module updates the time based on the time information input immediately before the error. This condition is called "non-synchronized state." The time is updated continuously by the CPU module, but time accuracy still drops. Therefore, it is necessary to recover the IRIG-B error to normal as soon as possible.

While the "not-synchronized state" continues, the SCS takes actions as follows.

- In the not-synchronized state, the difference from the standard time and the time discrepancy among SCSs gradually becomes larger as the time elapses. The difference from the standard time can reach up to ± 4.32 seconds/day and the time discrepancy among SCSs can reach up to 8.64 seconds/day. When debugging applications that require high time precision, it is recommended to connect a GPS simulator to prevent the system from entering the not-synchronized state.
- If the IRIG-B is not connected at the start of the SCS that uses the IRIG-B time synchronization, the SCS enters a not-synchronized state where the CPU module updates the time based on the V net time that was input when the SCS was started.
- If the IRIG-B is not connected at the start of the SCS that uses the IRIG-B time synchronization, a diagnostic information message notifying the cause of the last CPU shutdown and a diagnostic information message regarding the switching of the CPU control right, both of which are normally output when the SCS is started, will not be output.
  Once the SCS has been started or CPU control right switched, however, subsequent messages will be output correctly.
- You can connect normal IRIG-B signals to recover from the error state while the SCS is in a not-synchronized state. Once the signals are connected, the SCS will operate based on the correct time information input from the IRIG-B.

IMPORTANT

If the IRIG-B time synchronization is selected, connect the GPS unit via the IRIG-B first, and then start the SCS.

Time discrepancy caused by GPS failure

With stations connected to the V net where time synchronization among SCSs is performed by the IRIG-B time synchronization, a time discrepancy will occur if the GPS or IRIG-B interface fails because time synchronization by V net will not be carried out, either.

Table Appendix 4.1-2 Abnormality and time discrepancy

Abnormality	Phenomenon	Predicted Discrepancy
Antenna	When antenna error occurs, the standard time receiver will count the time based on its own clock. If the antenna error prolonged, the discrepancy may increase. If multiple SCSs are using the same receiver for time synchronization, the discrepancy will not occur for the SCSs. However, if they use different receivers for time synchronization, the time discrepancy among the SCSs may occur.	Discrepancy varies with the model of standard time receiver. It is necessary to query the vendor of the recover.
The Standard Time Receiver IRIG-B Cable IRIG-B Interface	When abnormality occurs, each SCS will count the time based on its own clock. If abnormality is prolonged, the discrepancy from the standard time and the discrepancy among SCSs may increase.	The time discrepancy among SCSs may occur. The maximum discrepancy is 8.64 sec/day.

Appendix 4.2 Inter-SCS safety communication in a V net domain

Inter-SCS safety communication is supported from SCS system program revision number R1.01.30 or later.

It is possible to perform Inter-SCS Safety Communication between SCS stations in the same V net domain or different V net domains to a range of up to 2 BCV or CGW hops.

If Inter-SCS safety communication is executed between the SCSs whose system program release number is prior to R1.02 in the different V net domains, the communication path cannot include Vnet/IP domains.

Appendix 4.3 Precautions when engineering CENTUM systems for using BCV and CGW

BCV and CGW engineering are performed by CENTUM ENG. In this case, follow the precautions below.

TCP/IP communication relay processing

In the CENTUM Integration Configuration, enable the “Transfer TCP/IP to FCS” in the setting items of BCV or CGW (one of the settings of the CENTUM system builder function), to allow the BCV or CGW to relay TCP/IP broadcast frames in both directions. This function allows the TCP/IP communication between the SENG and SCS to be performed across domains.

Time-related function

BCV and CGW have the function of transferring the time setting when time is set in the Adjust Time dialog on HIS or SENG.

SEE ALSO For more information about TCP/IP communication relay processing and time-related functions, refer to:

- Communication Devices Reference (IM 33J20B10-01EN)
- Communication Devices Reference (IM 33K03M10-50E)

Time discrepancy between domains

A maximum time discrepancy of 5 seconds occurs between two domains connected via a BCV. Times are not synchronized automatically when the time discrepancy increases between two domains connected via CGWs. One way to reduce the time discrepancy in either case is to synchronize each domain with an external absolute time. In this case, ensure that you do not transfer the time by BCV or receive the system time via CGW.

Appendix 4.4 System expansion with V net router connection

It is possible for SENG and/or SCS in a Vnet/IP domain to access an SCS in a V net domain. It is also possible to access an SCS in a V net domain from a CENTUM system and/or Exaopc client in a Vnet/IP domain via a V net router. The V net router is engineered by using the system builders of CENTUM.

When connecting a V net router, make sure to check that the load on the V net router caused by communication passing through the V net router will not become excessive.

TIP

V net routers (AVR10D) are classified into two types of behavioral specification, based on their hardware style and system software revisions. In this document, the two types are defined as "V net router of style S3 or above" and "V net router of a style below S3" as follows.

- V net router of style S3 or above
  When the style of AVR10D is S3 or above and the "operating mode" of V net router is set to [Standard Mode] in the System View of CENTUM VP R5.01 or later. Or, when the “operation mode” of V net router is set to [Extended Mode] in the System View of CENTUM VP R6.07 or later.
- V net router of a style below S3
  For all cases other than the condition described in "V net router of style S3 or later"

If no style is mentioned in explanations about the operation of the V net router in this document, the operation is common to all AVR10D styles and ProSafe-RS/CENTUM VP software revisions.

The following functions are implemented in the V net router connection configuration.

- Perform engineering and maintenance of SCS in a V net domain from SENG in a Vnet/IP domain
- Perform engineering and maintenance of SCS in a Vnet/IP domain from SENG in a V net domain
- Perform safety communication between SCS in a Vnet/IP domain and SCS in a V net domain
- Perform operation and monitoring of SCS in a V net domain from an HIS in a Vnet/IP domain
- Perform operation and monitoring of SCS in a Vnet/IP domain from an HIS in a V net domain
- Refer to data in an SCS in a V net domain and write data to an external communication FB from an FCS in a Vnet/IP domain
- Refer to data in an SCS in a Vnet/IP domain and write data to an external communication FB from an FCS in a V net domain
- Collect and display SOE and diagnostic information of an SCS in a V net domain from the CENTUM Sequence of Events Manager or ProSafe-RS SOE Viewer installed on an HIS in a Vnet/IP domain
- Install the ProSafe-RS SOE OPC Interface package on a PC in a Vnet/IP domain or V net domain and use the HIS or SENG as an OPC server to display SCS events on an OPC client (e.g., Exaquantum) in a Vnet/IP domain.
- Set up an Exaopc server in a Vnet/IP domain or V net domain and access data on the SCS from an OPC client (e.g., Exapilot) in a Vnet/IP domain.
- V net router of style S3 or above: Connect multiple Vnet/IP domains on a single V net domain
- V net router of style S3 or above: Execute SCS global switch communication (link transmission between FCS and SCS stations) between a V net domain and a Vnet/IP domain connected to a V net router.

- V net router of style S3 or above: Effect a time transfer from a V net domain to a Vnet/IP domain with the V net domain as the clock master, or vice versa
- The following specifications are applied when using a V net router of a style below S3
  The V net domain cannot be made the clock master, which means that you cannot change the time on the Vnet/IP domain even if you set the time from a SENG or HIS on the V net domain

Precautions when engineering CENTUM systems for using V net routers

V net routers are engineered using CENTUM ENG. Take the following precautions when engineering the routers.

TCP/IP communication relay processing

When the system consists of V net domains and Vnet/IP domains, enable [Transfer TCP/IP to FCS] in the setting items of the V net router (one of the settings of the CENTUM system builder function) to allow the V net router to relay the TCP/IP broadcast frames in both directions. This function allows the TCP/IP communication between the SENG and SCS to be performed across domains.

Transferring system time

- If you are using a V net router style S3 or above, open the "V net router" property from System View in CENTUM VP R5.01 or later, and specify the Transfer system time ([Transfer upper] or [Transfer lower]). This allows the time on either the V net domain or the Vnet/IP domain connected to the V net router to be transferred to another domain as the master.
- In the case of using a V net router style below S3, the Vnet/IP domain is always the upper domain. It is not possible to transfer the time from the lower domain to the upper domain.

Time discrepancy between domains

A maximum time discrepancy of 5 seconds occurs between two domains connected via a V net router. One way to reduce the time discrepancy is to synchronize each domain with an external absolute time rather than effecting a time transfer via the V net router.

Inter-SCS safety communication in systems in which a V net domain and a Vnet/IP domain are connected

Inter-SCS Safety Communications have different network reach ranges according to the specifications of V net router to be applied.

- Network range for style S3 or above
  In a communications route between two stations, network reach is up to 4 hops for connections between a V net domain and a Vnet/IP domain via a V net router, and up to 2 hops for connections between V net domains via a BCV or CGW.

  The following figure shows the domain configuration for the maximum network range when V net routers of style S3 or above are used.

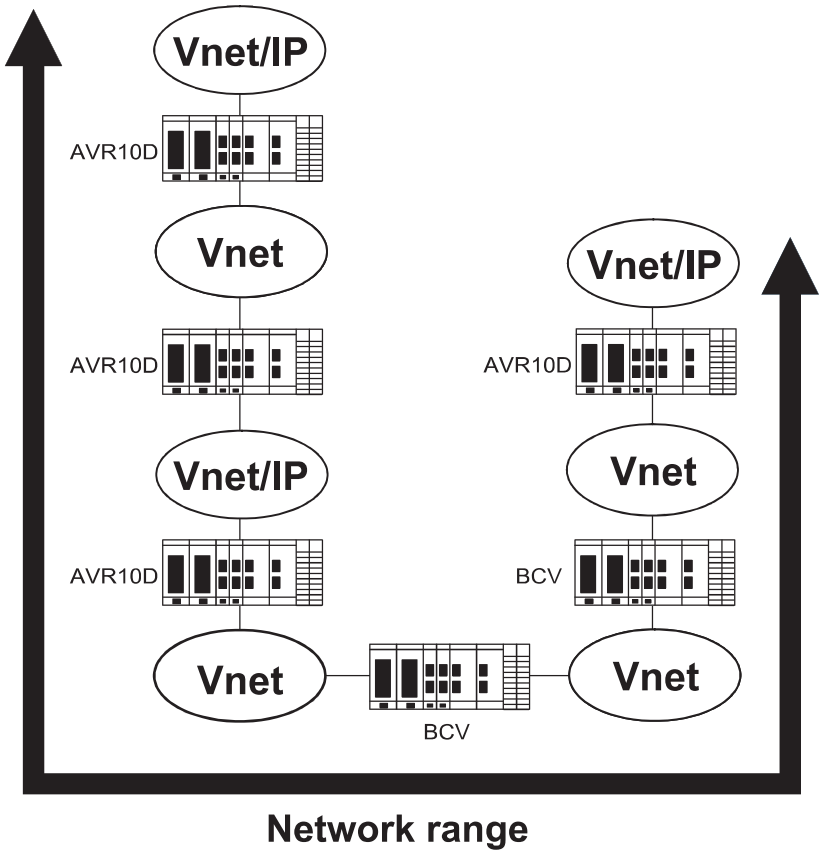

Figure Appendix 4.4-1 Network range when a V net router of style S3 or above is used

- Network range for style below S3
  The network reach range for inter-SCS Safety Communications is up to 2 hops for connections between V net domains via a BCV or CGW. It is not possible to have a V net domain on a mid-stream route communicating between Vnet/IP stations. That is, the configuration of SCSs on two Vnet/IP domains with a V net domain in between is not allowed.

  The following figure shows the domain configuration for the maximum network range when V net routers of a style below S3 are used.

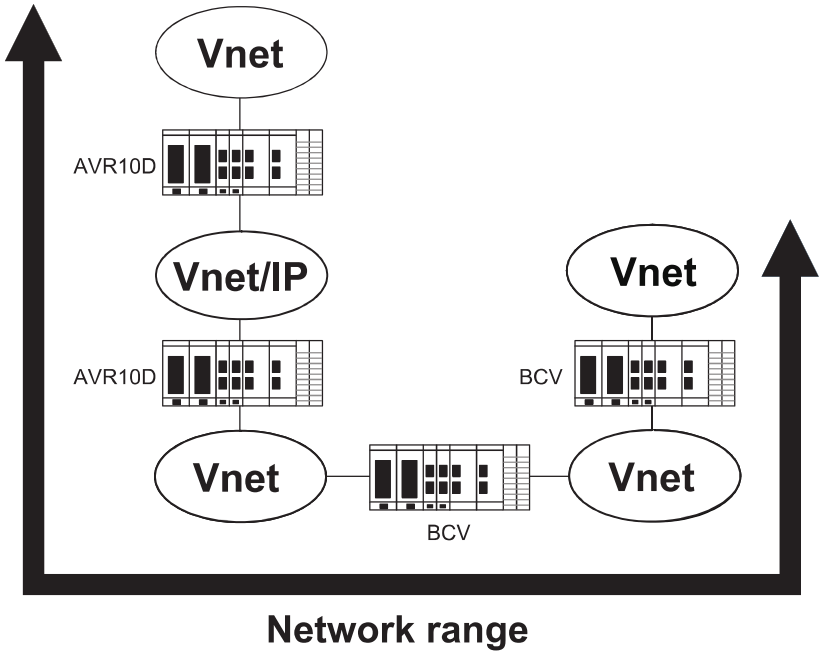

Figure Appendix 4.4-2 Network range when a V net router of a style below S3 is used

Virtual domain link transmission

If you are using a V net router style S3 or above, SCS Link Transmission Global Switch Communication is possible within a virtual domain by deploying the V net domain and Vnet/IP domain connected to that V net router as a single virtual domain.

To enable this feature, you must set up the V net router by using the CENTUM system builder function.

Issues to consider when using Virtual domain link transmission

The following are issues to consider when making a virtual domain link transmission.

- If you are using a V net router style S3 or above and CENTUM VP R5.01 or later, you can enable and disable virtual domain link transmission using the V net router settings included in the system generation function in CENTUM. If you set virtual domain link transmission for the V net router to [Enabled], link transmission is enabled between the V net domain and Vnet/IP domain connected to the V net router.
- To change the Enable/Disable setting for virtual domain link transmission, you will need to perform an offline download to the V net router.
- The guaranteed reach for virtual domain link transmission is within the same virtual domain as the sending station.
- Link transmission is not available between separate virtual domains. When connecting Vnet/IP domain A and B via V net, for example, Vnet/IP(A) – V net and Vnet/IP(B) – V net are discrete virtual domains. Consequently, link transmission can not be made between Vnet/IP(A) and Vnet/IP(B). When connecting V net domain A and B via Vnet/IP, V net(A) – Vnet/IP and V net(B) – Vnet/IP are discrete virtual domains likewise. Consequently, link transmission can not be made between V net(A) and V net(B).
- When you make a virtual domain link transmission, there must be no duplication of the station numbers inside the virtual domain.
- When two or more virtual domains are connected by a domain added to two or more virtual domains, station numbers must be unique in all these virtual domains.

Example use of Virtual domain link transmission

Virtual domain link transmission is useful in situations such as when migrating part of a V net domain and changing it to a Vnet/IP domain. The following figure shows an example configuration.

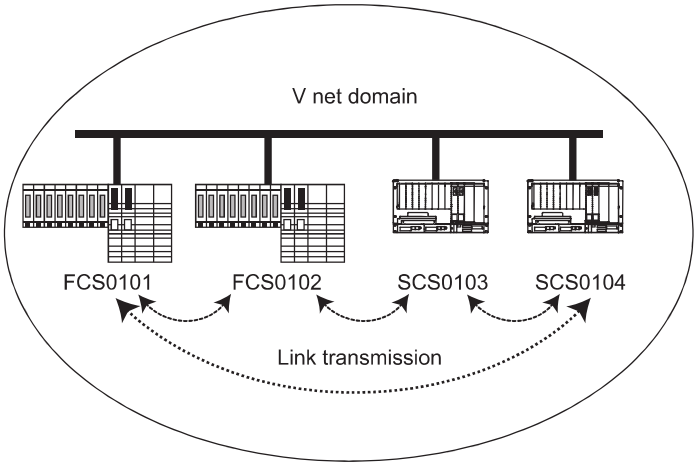

Figure Appendix 4.4-3 Example of the configuration of a Link transmission in a V net domain

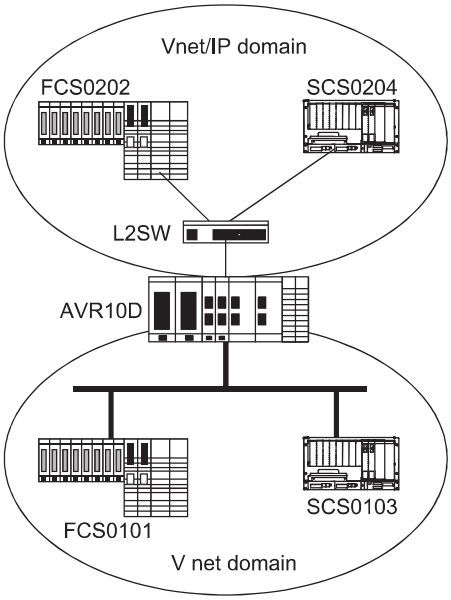
The following figure shows an example of a migration in which part of a V net domain is split into a Vnet/IP domain and an FCS0102 and SCS0104 are added to the Vnet/IP domain.



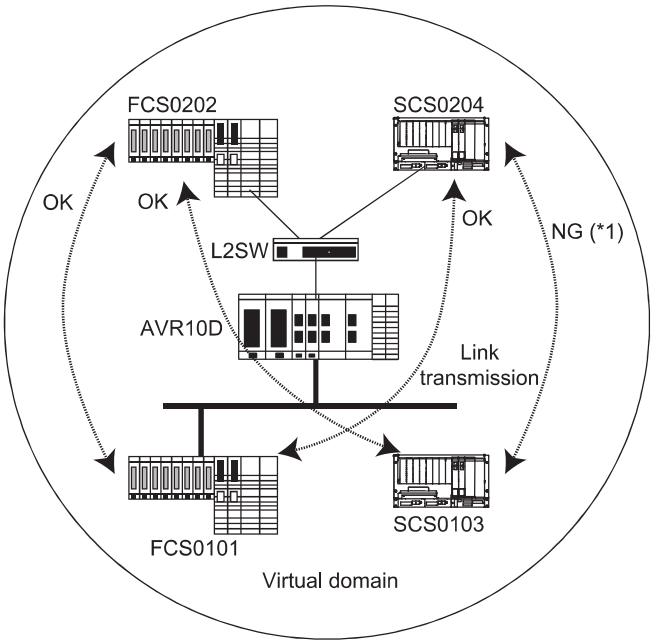


Figure Appendix 4.4-4 An example of a V net domain split into V net and Vnet/IP domains

The following figure shows an implementation of a link transmission.

*1: Virtual link transmission between SCSs (SCS link transmission safety communication) can not be executed.

Figure Appendix 4.4-5 Example of a Virtual domain link transmission

If the global switch for an SCS that has been migrated from V net to Vnet/IP is referenced by an FCS, it may, depending on the referencing method, be necessary to re-engineer the application concerned with the global switch in the FCS.

- If the global switch in the SCS is referenced by specifying the FCS as %GSnnnss (nnn: %GS number, ss: station number)

  You must re-engineer the FCS application if the SCS station number has been changed. It is not necessary to re-engineer the application if only the SCS domain number has been changed.

  Example: In the figure above, if FCS0101 references %GS001 in SCS0204, it is not necessary to change "%GS00104" referred to in the FCS0101 application.

- If the global switch in the SCS is referenced by specifying the FCS as %GSnnnSddss (nnn: %GS number, dd: domain number, and ss: station number)
  You must re-engineer the FCS application if the SCS domain number or station number has been changed.

  Example: In the figure above, if FCS0101 references %GS001 in SCS0204, it is necessary to change "%GS001S0104" referred to in the FCS0101 application to "%GS001S0204."

- If the global switch for an FCS that has been migrated from V net to Vnet/IP is referenced by an SCS.
  Provided that the station number does not change, it is not necessary to re-engineer the application concerned with the SCS link transmission. If the station number has been changed, you must change the station type in the Other Stations tab sheet of the SCS link transmission definition in SCS Link Transmission Builder, and redefine the wiring in Data Wiring Definition.

Revision information

Title : Engineering Guide Vol. 1

Manual No. : IM 32P01C10-01EN

Dec. 2023/11th Edition/R4.10 or later

F2.1.1	Deleted descriptions related to unsupported OS.
Appendix 3.4	Added the changed specifications in R4.10.

Jun. 2023/10th Edition/R4.09

C2.2, D5	Added description about versions that support iDefine.
C3, E1.3, E3.1	Updated descriptions of POU online change download.
Appendix 3.4	Added the changed specifications in R4.09.

Nov. 2022/9th Edition/R4.08

Appendix 3.4	Added the changed specifications in R4.08.

Jan. 2022/8th Edition/R4.07

D4.4	Updated descriptions of reflecting the POU that was defined by using iDefine.
D5.3	Added descriptions of cautionary notes on the use of the POWE/LOGE function.
E1.2	Updated descriptions of procedure for creating an application
Appendix 3.4	Added the changed specifications in R4.07.

Feb. 2021/7th Edition/R4.06

Introduction, A1, A4, A10.6, C2.2, D4.3, I5, I6	Updated FAST/TOOLS to CI Server.
Entire manual	Added descriptions of SIL 2 SCS.
A5.3	Updated the descriptions of when connecting N-IO nodes with fiber-optic cables.
B4	Updated the descriptions of PFD calculation.
C5.2.5	Added descriptions related to the new FB.
D1.4.1, Appendix 1.3.1	Updated the descriptions of P&ID Tag.
E1.3	Updated the descriptions of changing user-defined FB.
F2.1.1	Deleted descriptions related to unsupported OS.
Appendix 3.4	Added the changed specifications in R4.06.

Dec. 2019/6th Edition/R4.05

Introduction	Updated description of registered trademarks and trademarks.
A2.1, I4, I4.1, I4.1.1 to I4.1.9	Added description related to Forced I/O Viewer function.
A5, A7.2	Updated description due to supporting S2CP471.
A5	Improved descriptions regarding the optical ESB bus repeater
C1.2.6, C2.3, E1.2, E1.3, E2.1, E2.3, Appendix 3.4	Added description related to skipping of password of manual operation FB.
C2.2, D43, D5	Updated description due to improvement of workflow with iDefine.

D1.4.1, D1.4.2, D1.4.3, D1.4.5, D1.4.6	Updated description due to improvement of operability of Safety I/O Editor.
D1.5	Added description related to Safety I/O parameter profile.
D2.3, D2.4, D2.6, D2.7, F2.2	Updated description due to improvement of operability of Safety Communication I/O Editor.
D3.4, D3.5, E3.3	Updated description due to improvement of operability of IOM Definition editor.
D3.7, D3.8	Added description of import/export from IOM Definition editor.
E1.1	Improved descriptions of adding variables in online change download
E3.4	Improved descriptions of SCS project duplication procedure
H1.2	Added description of Operation data reset switch.
I5	Added description of stand-alone ProSafe-RS system.
I6	Added procedures and precautions for adding or replacing Vnet/IP devices.
Appendix 4.4	Changed descriptions due to supporting AVR10D extended mode

Aug. 2018/5th Edition/R4.04

Introduction	Updated description of registered trademarks of YOKOGAWA.
A1.1, I5	Changed description due to supporting virtualization platform.
C1.2.4, C2.1, Appendix2.1	Changed explanations due to changing the SCS Manager start-up method.
D1.4.1, D2.3, D5.1	Added descriptions due to adding the Safety I/O Editor mode and the Safety Communication I/O Editor mode.
D1.4, D2.3, D3.2	Updated the figure due to adding the SCS Manager start-up icon.
Appendix 1.3.2	Changed explanations due to changing the IOP upper/lower limit detection level of SAI143-H and S2MMM843.
Appendix 1.3.2	Changed explanations due to changing the transmitter error upper/lower limit detection level of SAI143-H and S2MMM843.

Oct. 2017/4th Edition/R4.03.10

Entire manual	Added Safety Communication I/O List and Safety Communication I/O Editor.
Introduction	Added the fire and gas communication module.
A2, A4, A5, A8, A9, A10, B4, B5, C2, C3, C5, H1, I1.1, C5, G2.2.9, F1	Added and updated descriptions regarding the safety subsystem communication function.
A5, A8, A9, G2.2, G2.2.9, H3.2, I1.2, Appendix 2.2	Added descriptions regarding the fire and gas communication module.
A10.6, C1.1, C3, E1.2	Updated descriptions due to functional enhancement of Version Control Tool and Master Database Restoring Function.
C1, E1.3	Added descriptions of Command Line.
Part D	Added descriptions of engineering based on the safety communication I/O list. Deleted descriptions of grid rules and moved them to Engineering Guide Vol. 2 (IM 32P02C10-01EN). Added and updated descriptions of RS Generation Manager. Added precautions when performing engineering by using iDefine.
D	Added descriptions of settings with PROFINET Configurator.

E1.5	Added precautions related to the fire and gas communication module when performing online change download.
H3.1.2	Added FPGA revision to the IOM Report display format.
I1.4	Added descriptions regarding maintenance of field wireless system devices.
I2	Reorganized the descriptions of proof tests and tests for improving the rate of operation.
Appendix 3.4	Added descriptions of major changes in R4.

May 2017/3rd Edition/R4.03

Entire manual	Changed description regarding the start menu
Introduction	Deleted Windows Vista from explanation of trademarks
A1.2, A1.3, H7, I4.7	Added explanation of Vnet/IP ring topology
A5, B5, E1.6, H3.1.2, H3.1.3, H4, Appendix 1.2, Appendix 1.3, Appendix 2.2	Added explanation of S2MDV843 and changed explanations in accordance with addition of S2MDV843
C1.2.5, C2.3, C5.2.5, D1.1.2, E1.2, E1.3, E2.1, E2.3, E3.1, A1.2, A1.3.2	Added explanation of the fire and gas equipment transmitter power OFF/ON function
C2.3, D1.1.2, E1.3, E2.1, A1.3.2	Added explanation of the chattering alarm suppression function
D2.4	Changed explanation of function blocks
E3.1, E3.2, E3.3, E3.4	Added explanation of the Project Comparing Tool
F2.1.1	Added specifications of the Node Number Setting Tool

Oct. 2016/2nd Edition/R4.02

Entire manual	Changed the symbols that indicate warning and caution.
Introduction	Updated descriptions in "■ Safety, Protection, and Modification of the Product," "■ Symbols," and "■ Trademark Acknowledgments." Added a new term in "■ Full Names and Simplified Terms."
A2.1, B1, B2, C1.2, C2.1, C2.2, D1, D1.1, D1.2, D1.3, D1.3.4, D2, D2.1, D2.2, D2.3, D2.4, E2.2	Added explanations on iDefine
Part A, Part C, Part D, Appendix 2, Appendix 3	Changed layout
A6, A10, A10.2, A10.3, A10.5, C2.3, C3, C6, C7, C9, D1.1, E1.2, E1.5, Appendix 2, Appendix 2.1	Changed explanations

10th Edition

Introduction

This manual describes the operating procedures and precautions when building application logics in ProSafe-RS engineering. It also describes the details of engineering and maintenance for connecting ProSafe-RS to CENTUM VP and other systems. You can read it for your necessary information.

For the overview of ProSafe-RS system, the points at the engineering, and the cautionary notes, as well as a description of how to design, make, operate, and maintain a safety system using ProSafe-RS, based on the workflow of engineering, refer to Engineering Guide Vol. 1.

If you are using YFGW520, replace the term “YFGW510” with “YFGW520” in the User’s Manual. For information on how to use YFGW520, refer to “YFGW520 Field Wireless Access Point (IM 01W02E02-01EN).”

This manual consists of the following parts:

- Part A Configuring application
  This part describes the operating procedures and precautions when building application logics in ProSafe-RS engineering.
- Part B CENTUM integration
  This part describes the engineering and maintenance when integrating ProSafe-RS and CENTUM.
- Part C SOE OPC interface
  This part mainly describes specifications of the SOE OPC Interface of ProSafe-RS and compatibility with the OPC specifications. It also describes the setup procedures required to connect to OPC clients using the SOE OPC Interface.
- Part D Subsystem communication
  Subsystem communication is used for connections between the ProSafe-RS and other systems. This part describes the subsystem communication functions and setting items required for connections with other systems.
- Part E Safety subsystem communication
  Safety subsystem communication provides safe communications between ProSafe-RS and other subsystem devices. This part describes the safety subsystem communication function and setting items required to use safety subsystem communication.
- Part F Modbus slave communication
  Modbus slave communication is used for connections between the ProSafe-RS and other systems. This part describes the definition of communication modules, definition of addresses of Modbus devices, and data setting using Modbus slave communication, which are required for connections.
- Part G DNP3 slave function
  DNP3 communication is used for connections between ProSafe-RS and other systems. This part describes the DNP3 slave function as well as engineering and maintenance on the SENG.
- Appendix
  This part describes information about engineering of subsystems.

  This part also describes the DNP3 Field Device Profile.

Safety Precautions for Use

Safety, Protection, and Modification of the Product

- To protect the system controlled by the Product and the Product itself and to ensure safe operation, please observe the safety precautions described in this Manual. Yokogawa Electric Corporation ("YOKOGAWA") assumes no liability for safety if users fail to observe the safety precautions and instructions when operating the Product.
- If the Product is used in a manner not specified in the User's Manuals, the protection provided by the Product may be impaired.
- If any protection or safety circuit is required for the system controlled by the Product or for the Product itself, please install it externally.
- Be sure to confirm the specifications and required settings of the devices that are used in combination with the Product by referring to the instruction manual or other documents of the devices.
- Use only spare parts that are approved by YOKOGAWA when replacing parts or consumables of the Product.
- Do not use the Product and its accessories such as power cords on devices that are not approved by YOKOGAWA. Do not use the Product and its accessories for any purpose other than those intended by YOKOGAWA.
- Modification of the Product is strictly prohibited.
- The following symbols are used in the Product and User's Manuals to indicate the accompanying safety precautions:

Indicates that caution is required. This symbol for the Product indicates the possibility of dangers such as electric shock on personnel and equipment, and also indicates that the user must refer to the User's Manuals for necessary actions. In the User's Manuals, this symbol is used together with a word "CAUTION" or "WARNING" at the locations where precautions for avoiding dangers are described.

<French> Signale qu'il faut faire preuve de prudence. Ce symbole pour le produit signale la possibilité d'un danger pour le personnel et l'équipement comme un choc électrique, et signale également que l'utilisateur doit se référer au Manuel de l'utilisateur afin de prendre les mesures nécessaires. Dans le Manuel de l'utilisateur, ce symbole est utilisé conjointement avec la mention «CAUTION» ou «WARNING» aux endroits où sont décrites les précautions pour éviter les dangers.

Indicates that caution is required for hot surface. Note that the devices with this symbol become hot. The risk of burn injury or some damages exists if the devices are touched or contacted.

<French> Signale qu'il faut faire preuve de prudence avec la surface brûlante. Les appareils sur lesquels est apposé ce symbole risquent de devenir brûlants. Tout contact physique ou matériel avec ces appareils risque de provoquer des brûlures ou des dommages.

Identifies a protective conductor terminal. Before using the Product, you must ground the protective conductor terminal to avoid electric shock.

Identifies a functional grounding terminal. A terminal marked "FG" also has the same function. This terminal is used for grounding other than protective grounding. Before using the Product, you must ground this terminal.

Indicates an AC supply.

Indicates a DC supply.

| Indicates that a component such as a power supply switch is turned ON.

○ Indicates that a component such as a power supply switch is turned OFF.

Notes on Handling User's Manuals

- Hand over the User's Manuals to your end users so that they can keep the User's Manuals on hand for convenient reference.
- Thoroughly read and understand the information in the User's Manuals before using the Product.
- For the avoidance of doubt, the purpose of the User's Manuals is not to warrant that the Product is suitable for any particular purpose but to describe the functional details of the Product.
- Contents of the User's Manuals are subject to change without notice.
- Every effort has been made to ensure the accuracy of contents in the User's Manuals. However, should you have any questions or find any errors, contact us or your local distributor. The User's Manuals with unordered or missing pages will be replaced.

Warning and Disclaimer

- Except as specified in the warranty terms, YOKOGAWA shall not provide any warranty for the Product.
- YOKOGAWA shall not be liable for any indirect or consequential loss incurred by either using or not being able to use the Product.

Notes on Software

- YOKOGAWA makes no warranties, either expressed or implied, with respect to the Software Product's merchantability or suitability for any particular purpose, except as specified in the warranty terms.
- Purchase the appropriate number of licenses of the Software Product according to the number of computers to be used.
- No copy of the Software Product may be made for any purpose other than backup; otherwise, it is deemed as an infringement of YOKOGAWA's Intellectual Property rights.
- Keep the software medium of the Software Product in a safe place.
- No reverse engineering, reverse compiling, reverse assembling, or converting the Software Product to human-readable format may be performed for the Software Product.
- No part of the Software Product may be transferred, converted, or sublet for use by any third-party, without prior written consent from YOKOGAWA.

Documentation Conventions

Symbols

The following symbols are used in the User's Manuals.

 WARNING	Indicates precautions to avoid a danger that may lead to death or severe injury.
 CAUTION	Indicates precautions to avoid a danger that may lead to minor or moderate injury or property damage.
IMPORTANT	Indicates important information required to understand operations or functions.
TIP	Indicates additional information.
	Indicates referenced content. In online manuals, you can view the referenced content by clicking the links that are in green text. However, this action does not apply to the links that are in black text.

Typographical Conventions

The following typographical conventions are used throughout the User's Manuals.

Commonly Used Conventions throughout the User's Manuals

- Δ Mark
  Indicates that a space must be entered between character strings.
  Example:

  ```
  .ALΔPIC010Δ-SC
  ```

- Character string enclosed by braces { }
  Indicates character strings that may be omitted.

  Example:

  ```
  .PRΔTAG{Δ.sheet name}
  ```

Conventions Used to Show Key or Button Operations

- Characters enclosed by brackets [ ]
  When characters are enclosed by brackets in the description of a key or button operation, it indicates a key on the keyboard, a button name in a window, or an item in a list box displayed in a window.

  Example:

  To alter the function, press the [ESC] key.

Conventions of a User-defined Folder

- User-defined folder name enclosed by parenthesis ( )
  User definable path is written in a pair of parentheses.

  Example:

  ```
  (RS Project Folder)\SCS0101
  ```

If the RS Project Folder is `C:\MYRSPJT`, the above path becomes `C:\MYRSPJTSCS0101`.

Drawing Conventions

Drawings used in the User's Manuals may be partially emphasized, simplified, or omitted for the convenience of description.

Drawings of windows may be slightly different from the actual screenshots with different settings or fonts. The difference does not hamper the understanding of basic functionalities and operation and monitoring tasks.

Explanation of Hardware and Software Behaviors in the User's Manuals

In the User's Manuals, system behaviors are explained assuming that the latest versions of YOKOGAWA software and hardware at the time of publication of the User's Manuals are installed.
If additional precise information about the safety of legacy versions of software or hardware is required, a link to the corresponding explanation is provided. Please refer to the information according to your system.

Definitions of Node and Module Terms

In the User's Manuals, nodes and modules are referred to by using collective terms, another terms, or abbreviations based on the following definitions:

- Definitions of nodes
  - Node: A node is a collective term for an FIO node and an N-IO node.
  - FIO node: This is a collective term for a safety control unit, a safety node unit, and a unit for optical ESB bus repeater module.
  - CPU node: This is another term for a safety control unit. The abbreviation of safety control unit is SCU.
  - I/O node: This is another term for a safety node unit. The abbreviation of safety node unit is SNU.
  - N-IO node: This is a collective term for a node interface unit and an N-IO I/O unit. The abbreviation of node interface unit is NIU.
- Definitions of modules
  - I/O module: This is a collective term for an FIO I/O module and an N-IO I/O module.
  - FIO I/O module: This is a collective term for an analog I/O module and a digital I/O module for FIO, and a communication module.
  - N-IO I/O module: This is a collective term for the modules that can be mounted on an N-IO I/O unit.
  - AIO/DIO module: This is a collective term for an analog I/O module, a digital I/O module, and a universal type I/O module.
  - Analog I/O module: This is a collective term for an analog input module and an analog output module.
  - Digital I/O module: This is a collective term for a digital input module and a digital output module.
  - Universal type I/O module: This is a collective term for the I/O modules for which the channel signal category can be changed by software.

- Input module: This is a collective term for an analog input module, digital input module, and a universal type I/O module with defined input channels.
- Output module: This is a collective term for an analog output module, digital output module, and a universal type I/O module with defined output channels.
- Communication module: This is a collective term for a serial communication module, an Ethernet communication module, and a fire and gas communication module.

Full Names and Simplified Terms

In the User's Manuals, simplified terms listed in the following table are used.

Table Info-1 Full Names and Simplified Terms

Full Name	Simplified Term
Automation Design Suite	AD Suite
Automation Design Organizer	AD Organizer
Automation Design Server	AD Server
Automation Design project	AD project
Automation Design Master Database	ADMDB
Automation Design Suite Administration Tool	ADS Administration Tool
iDefine for ProSafe-RS	iDefine
Modification Package	ModPack
SCSV1-S (SCS supporting the SSC10S/SSC10D safety control units)	SCSV1
SCSP1-S (SCS supporting the SSC50S/SSC50D safety control units)	SCSP1
SCSP2-S (SCS supporting the SSC60S/SSC60D safety control units)	SCSP2
SCSP3-S (SCS supporting the S2SC70S/S2SC70D safety control units)	SCSP3
SCSL2-S (SCS supporting the L1SC70S/L1SC70D safety control units)	SCSL2
SCSU1-S (SCS supporting the SSC57S/SSC57D safety control units)	SCSU1

A. Configuring application

This section describes how to configure applications after design completion. Depending on the purpose, the following applications can be created:

- Application logic for implementing the safety system
- Applications that use safety communication between multiple SCSs
- Applications for event analysis that utilize SOE
- Applications that are integrated with CENTUM and CI Server

TIP

CI Server Integration Package also contains FAST/TOOLS Integration function. If FAST/TOOLS Integration is used, replace the term “CI Server” with “FAST/TOOLS” in the user's manual.

- Applications that connect with other systems that utilize Modbus communication and SOE OPC

When an application is created, you need to use Safety Analyzer to check the application that is created.

A1. Precautions for creating an application

This section describes the precautions to take when creating applications. Before creating the actual application, make sure you have read and understood the precautions.

Editing project files

Files in the SCS project folder must be edited only in the SCS Manager and AD Organizer.

Precautions for creating an application

You need to observe the following precautions when creating an application logic:

IMPORTANT

- A value must be set to each input parameter of a function (FU) or function block (FB). Also to each output parameter of an FU. They cannot be omitted.
- The data type of variables received by FU and FB must be in accord with that of input/output parameters in FU and FB.

- Arrays cannot be used in a program of a function block diagram (FBD) or ladder diagram (LD). When the Integrity Analyzer finds an array, an error will result.
- In the application logic, POU called from a program can have a hierarchy of up to 8 levels. If the hierarchy exceeds 8 levels, the Integrity Analyzer generates an error.
- Instance names connected in the hierarchy should be defined so as to have up to 80 characters.
- Four FBs (ANN, SOE_B, SOE_I, and SOE_R) are Interference-free. However, the Integrity Analyzer does not issue any alarms. As the four FBs do not have output parameters, using the FBs in FBD (Function Block Diagram) has no effects on the safety loop. On the other hand, these FBs have ENO output parameters when used in LD (Ladder Diagram) and thus make sure that they do not affect the safety loop.
- When looping the output of FU/FB back without using intermediate variables as shown in left of the following figure, a warning is issued at building. To avoid this, you should use a variable in looping back the output, specified in right of the following figure. You need to place the output variable on the right of FU/FB in the loop back.

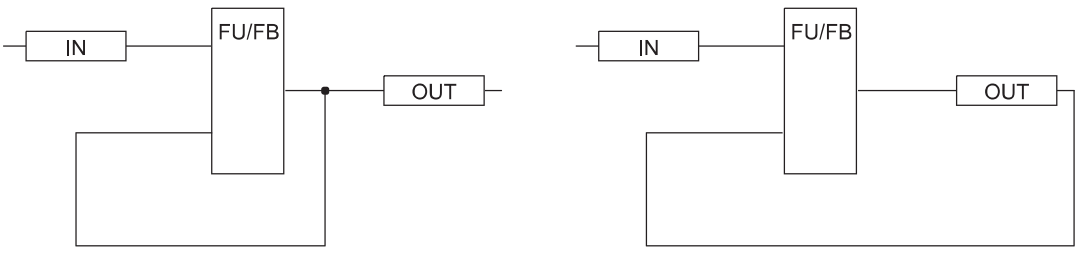

Figure A1-1 Example when a warning is output (left) and example when a warning is not output (right)

- Integrity Analyzer displays yellow warning icons if it detects Null functions of LD. Null functions refer to diagrams where one of the signals that branch out in a parallel coupling is directly connected and the value of the contact connected to the other line is ignored. In the example in the following figure, the value of the variable bIN is ignored.

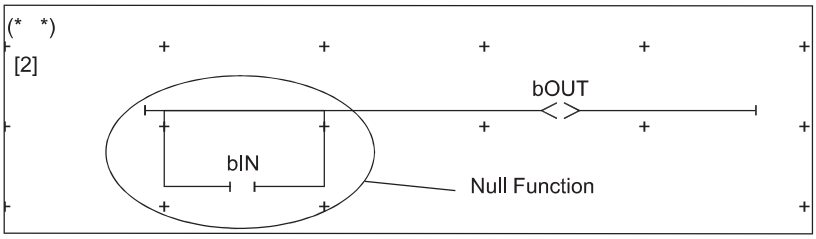

Figure A1-2 Example of Null function in LD

- An FB with a variable name assigned must not be called more than once. Be especially careful when you copy and paste an FB. For example, if the same REPEATTIMER is used in two programs, the timer may count at double-speed. If Integrity Analyzer detects one instance that is called multiple times, it raises a warning.
- If a calculation of equal (=) or Not equal (<>) is used for real numbers, the Integrity Analyzer will display a warning message.
- If variables of COM_BOOL type, COM_DINT type, or COM_REAL type undefined in Binding List View are used in POU, the Integrity Analyzer displays a warning message.
- At least one output parameter must be wired for function blocks that have no input parameter. Otherwise, such function blocks are not executed. The following FBs are appropriate: ECW_B, ECW_I, ECW_R, SYS_DIAG, SYS_IOALLST, SYS_TIME, SYS_ALARM, SYS_NETST, SYS_ESBINF, SYS_PSUDSP, SYS_CPUDSP, SCI_B, SCI_I, SCI_R, PSI_I, PSI_R, PNI_I, PNI_R, LTRCV, LTFCS.
- If you repeat building operations on the SCS Manager, the database size of SCS projects become larger. If the database size becomes too large, phenomena such as the build time becoming very long occur. In order to avoid this, execute [Compact Database] at an appropriate timing.

Precautions and actions to take when an abnormal calculation error occurs

IMPORTANT

If abnormal calculations such as division by zero, access to the outside of an array, overflow in floating-point calculation, and overflow in casting occur during POU execution, SCS behaves according to the specification made by [Behavior at Abnormal Calculation] in the SCS Constants Builder. If this specification is [SCS fails] (default), the SCS stops. If you specify [SCS continues], the SCS continues the operation without failing, but there is a potential risk that it cannot properly respond upon generation of a demand related to the corresponding POU while an abnormal calculation persists. Be sure to take measures to prevent abnormal calculations in applications and, if necessary, specify [SCS continues] just in case.

If SCS continues operating under the conditions where it cannot properly respond to related demands due to occurrence of abnormal calculation, the user must identify the condition immediately and take corrective measure to solve the error by modifying the application. If [SCS continues] is specified and an abnormal calculation occurs, the occurrence of error and the cause are notified to SENG and HIS via diagnostic information messages. Moreover, if you use the SYS_CERR function block, it is possible to output the abnormal calculation status to external devices by the application.

- If division by zero occurs in division of REAL- or DINT-type, SCS behaves according to the specification of [Behavior at Abnormal Calculation] in the SCS Constants Builder.
- If you specify a positive constant or 0 to an array index, index range check is performed at building and a build error will occur if the index points to the outsides of the array. On the other hand, if you specify a variable, expression, or negative constant for an array in-

dex, the range check is not performed at building. In this case, if access to the outside of the array occurs, SCS behaves according to the specification of [Behavior at Abnormal Calculation] in the SCS Constants Builder.

- If you convert floating point data to DINT with the ANY_TO_DINT function, SCS behaves according to the specification of [Behavior at Abnormal Calculation] in the SCS Constants Builder if the converted result is larger than the maximum value or smaller than the minimum value of integer-type data (that is, when an overflow occurs).
- Always use DINT-type for ANY_TO_TIME to restrict the value in the range from 0 to 86400000. If you enter a value outside this range, a correct TIME value cannot be obtained. In particular, if you specify a REAL value larger than 4294967295 (i.e., the maximum unsigned 32-bit integer) or a REAL value smaller than -2147483648 (i.e., the minimum signed 32-bit integer), SCS behaves according to the specification of [Behavior at Abnormal Calculation] in the SCS Constants Builder.

Note that, in the following cases, SCS continues the operations regardless of the specification of [Behavior at Abnormal Calculation] but the intended calculation result cannot be obtained.

- If you input 0 or less to LOG, a fixed value (-1E35) is output.
- If you input 0 or less as the denominator for MOD, a fixed value (-1) is output. In this case, there is no distinction from the case where -1 is obtained from the correct calculation.
- If an overflow occurs in calculation of integer values, the calculation result is not limited by the maximum value. Be sure to apply limits on the result of calculation if it is expected that the maximum value is exceeded.
- Be sure to specify the TIME-type value to less than 24 hours. No error occurs at building even if 24 hours is exceeded. Since the timer returns to 0 hours when it reaches 24 hours, it never reaches time beyond 24 hours. For example, if you set the timeout of TON to 25 hours, TON will no longer time out, which will be different from the intended operation.

SEE ALSO

For more information about considerations for calculation errors, refer to:

“■ Coding” in 3., “Guidelines for developing application logic” in POU Reference Manual (IM 32P03B20-01EN)

For more information about behavior of SCS upon calculation errors, refer to:

G2.1.3, “Behavior at abnormal calculation” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

A1.1 Creating an application logic

This section describes the definitions of variables and parameters, user-defined function blocks, and user-defined functions that are required when you create an application logic.

Definitions of variables and parameters

Use Dictionary View of SCS Manager to define I/O variables, internal variables and parameters used in an application logic.

It is possible to perform the following operations in Dictionary View.

- Creation and deletion of variables
  It is possible to create and delete variables used in application logics.
- Creation and deletion of parameters
  It is possible to create and delete parameters used in function blocks and functions.

You can define variables directly on the Dictionary View or by using the Safety I/O Editor of AD Suite and iDefine.

I/O variables can be defined by using AD Suite, while internal variables and FB instances can be defined by using iDefine.

Variables that are defined with AD Suite and iDefine are read-only on the Dictionary view and cannot be edited.

Variables defined using other tools will not be affected when reflecting variables that are defined with AD Suite and iDefine into the Dictionary view.

For example, after changing I/O variables using AD Suite and reflecting the values into the Dictionary View, internal variables and FB instances defined using iDefine and variables defined directly by the user on the Dictionary View are not changed.

Similarly, changing internal variables and FB instances defined using iDefine and reflecting the values into the Dictionary View does not change the I/O variables defined using AD Suite and the variables defined directly by the user on the Dictionary View.

SEE ALSO For more information about Dictionary View details, refer to:

"Dictionary View" in "Workbench" in the Workbench User's Guide

User-defined Function Blocks and user-defined functions

ProSafe-RS provides standard function blocks and functions such as "TON" and "AND" but the user can define customized function blocks and functions to implement a logic used commonly in several applications.

Function blocks and functions defined by users are called user-defined function blocks and user-defined functions, respectively.

User-defined function blocks and user-defined functions can be used in any programs, function blocks and functions in the same way as standard function blocks and functions.

You can define user-defined function blocks and user-defined functions by using the Multi-Language Editor or iDefine.

User-defined function blocks and user-defined functions that were created using iDefine cannot be edited in the Multi-Language Editor. Similarly, user-defined function blocks and user-defined functions that were created using the Multi-Language Editor cannot be edited in iDefine.

A1.2 Windows used to create application logic

You can create application logics by using the Link Architecture View of SCS Manager and Multi-Language Editor, or by using iDefine. Application logics that were created using iDefine cannot be edited in the Multi-Language Editor. Similarly, applications that were created using the Multi-Language Editor cannot be edited in iDefine.

SEE ALSO For more information about creating an application logic by using iDefine, refer to:

iDefine User Guide (PR03076-MAN-970_01)

Link Architecture View

You can create, remove or copy POUs in Link Architecture View of SCS Manager. You can change the execution order of POUs on the Link Architecture View. After reflecting the POU that is created by using iDefine, you can change the execution order, add and delete POUs that were created on the Link Architecture View as needed.

To show Link Architecture View, click the [Link Architecture View] on the toolbar of SCS Manager.

SEE ALSO For more information about Link Architecture View details, refer to:

"Link Architecture View" in "Workbench" in the Workbench User's Guide

Multi-Language Editor

Multi-Language Editor is used to create and edit application logics for SCSs using the following programming languages defined by IEC 61131-3.

The following three languages can be used in ProSafe-RS.

- Function block diagram (FBD)
- Ladder diagram (LD)
- Structured Text (ST)

A window for editing an FBD, a window for editing an LD and a window for editing an ST can be opened at the same time in one Multi-Language Editor. In order to create a new POU, select a language by selecting[Insert] > [Add Program], [Add Function], or [Add Function Block] menu in Link Architecture View. Multi-Language Editor automatically launches.

IMPORTANT

Do not use ST for creating Programs.

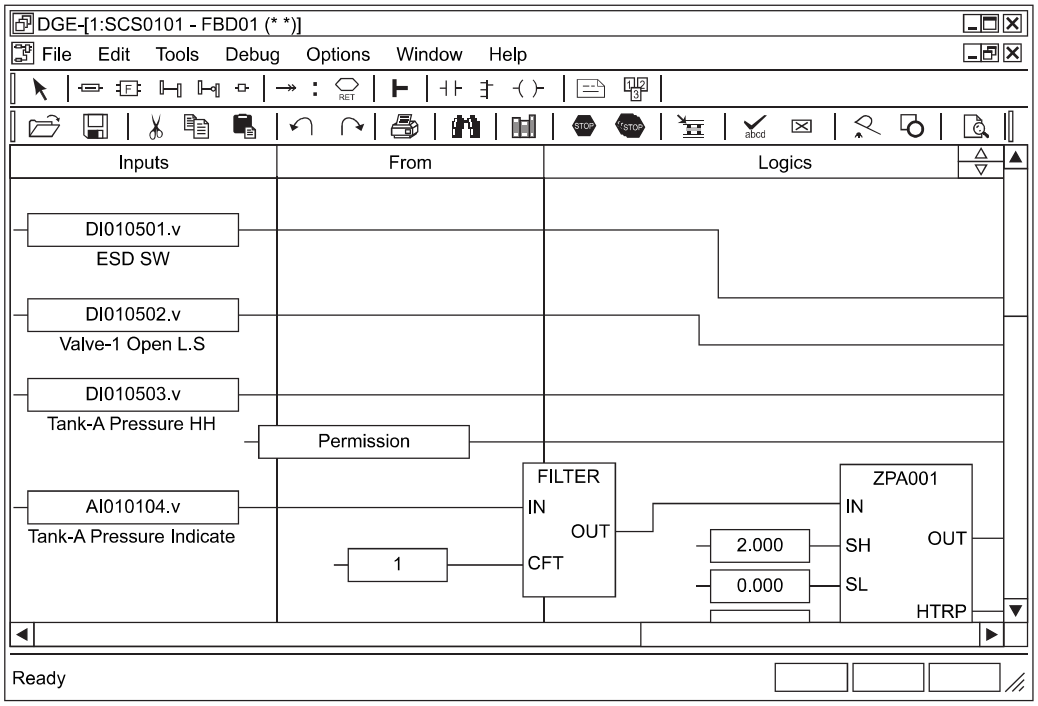

Figure A1.2-1 Multi-Language Editor window structure (example of editing an FBD program)

TIP

The scripts of FB and FU written in Structured Text are decorated with the following colors:

- Structured Text Statements of IEC 61131-3: Pink
- Numbers: Brown
- Comments: Green
- Other Texts: Black
  The background color can be changed. Click [Option] menu to open Customize dialog box. On the "Colors and Fonts" tab, choose the [ST editor] to change the background color. However, the color of texts cannot be changed.

Showing or hiding the toolbar in the Multi-Language Editor window is the same as that in SCS Manager.

POUs that were created using iDefine cannot be edited in the Multi-Language Editor. Similarly, POUs that were created using the Multi-Language Editor cannot be edited in iDefine.

SEE ALSO

For more information about showing or hiding the tool bar on the Multi-Language Editor window, refer to:

"■ Show/hide SCS Manager toolbars" in A10.2, "SCS Manager" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about Multi-Language Editor, refer to:

"Multi-Language Editor" in "Language Editor" in "Workbench" in the Workbench User's Guide

A2. Creating an application for the diagnostic function of the SCS

The SCS notifies the user of the status of the SCS in operation, the information on detected errors and on operations by the user. Monitoring the notified information enables the user to take appropriate actions. The SCS controls to bring the process to a safe state when the SCS detects an error in itself. The user is able to create applications for the diagnostic function of the SCS.

This section describes the following:

- Overall diagnostic function of SCS
- The SCS operations at fault detection that should be considered when creating an application for error detection

Overall diagnostic function of SCS

SCS has diagnostic functions for hardware and software.

When SCS detects an error by diagnosis, actions corresponding to the error are taken. A notification of the error appears in the Diagnostic Information Message and Status Display to alert the user.

Diagnosis for hardware

SCS carries out diagnosis with the following timing to check whether various types of hardware including I/O modules are in the normal state.

- At the start of the hardware.
- At specified periodical intervals during operation.

Diagnosis for software

SCS carries out diagnosis to check that the following actions of software are correctly performed.

- Task actions
- Application execution time

The following table shows an overview of actions when SCS detects an error by diagnosis.

Table A2-1 SCS actions on fault detection by SCS diagnosis

Fault level (*1)	Definition	Overview of SCS actions
Fatal error	Fatal hardware/software errors disabling continuous operation of the SCS.	CPU on both sides stops (SCS FAIL). Stopping CPU results in the change of output values of all output modules to the Output value at fault (All outputs shutdown) (*2)
Major error	This is not a fatal error that stops the CPU, but an error that disables some of the execution function of the application logic.	SCS performs an action against the error and notifies the application logic of the error state. In this case, creating an application by the user allows actions to be performed at the occurrence of an error (Shutdown actions (*2), and so on.) SCS notifies the user that an error occurs with diagnostic information message and the Status Display.

Continues on the next page

Table A2-1 SCS actions on fault detection by SCS diagnosis (Table continued)

Fault level (*1)	Definition	Overview of SCS actions
Minor error	Other errors • Error that have no influence on the application logic execution function itself, such as switching in redundant configuration • Errors related to functions not associated with the application logic execution functions • Operation mistakes by users	The application logic execution function continues. SCS notifies the user with diagnostic information message and the Status Display that an error occurs. Notification to the application logic depends on what kind of error occurs. When a module in a dual-redundant configuration fails, the failed module is regarded as FAIL state and switching-over to the stand-by is executed.

*1: Classification of error level
The SCS classifies the error level according to the result of error analysis, which determines the type of error that occurred, as well as the system state at which the error happened.
*2: Shutdown actions
Shutdown actions control output modules in appropriate conditions. There are three kinds of shutdown actions.
- The Shutdown that is operated with the logic that was created by user.
- Shutdown that makes CPU hold the output value in a failed channel.
- Shutdown of the output modules when they detect an error in communication with the CPU.
  When all output modules are shut down by stopping CPU due to a fatal error, this is called All Output Shutdown.

Actions on error detection

To keep the process in a safety state when an error is detected by the diagnosis of SCS, you need to understand the actions of the system in the case of error and design the safety application appropriately for the error levels.

Major SCS errors and actions of I/O modules against the error status are shown as follows.

They are very important issues in designing the safety applications.

Table A2-2 Actions on error detection

Failure location	Cause	Configuration	Actions	Fault level
CPU module	Hardware failure CPU node failure Software failure	Single	CPU stops. All output modules output the Output value at fault. (All output shutdown)	Fatal error
		Dual-redundant	CPU on failure side stops. The control is continued by switching the control right.	Minor error
Input module	Hardware failure	Single	The Input value at fault is set to all input channels of the module and data status changes to BAD.	Major error
		Dual-redundant	The control is continued by switching the control right.	Minor error
Input channel	Failure of Hardware for individual channel Failure on field side	Single (*1)	The Input value at fault is set to failed input channels and data status changes to BAD.	Major error
		Dual-redundant (*2)	When a failure is on the field side, the same action as the single configuration is performed.	Major error
			When a failure other than the above occurs, the control is continued by switching the control right.	Minor error
Output module	Hardware failure	Single	The output becomes 0 (*3) for all the output channels on the module, they are put in output disable state, and their data statuses change to BAD.	Major error
		Dual-redundant	The control is continued by switching the control right.	Minor error

Continues on the next page

Table A2-2 Actions on error detection (Table continued)

Failure location	Cause	Configuration	Actions	Fault level
Output channel	Failure of Hardware for individual channel Failure on field side	Single (*1)	When output shutoff switch works (*4), the output becomes 0 (*3) for all the output channels on the module, they are put in output disable state, and their data statuses change to BAD.	Major error
			Others except for the above case: Output value at fault is set to physical data of this channel and it is put in output disable state, and data status changes to BAD state.	Major error
		Dual-redundant (*2)	When a failure is on the field side, the same actions as the single configuration are performed.	Major error
			When a failure other than the above occurs, the control is continued by switching the control right.	Minor error

*1: When the module is in single configuration
*2: When the module is in dual-redundant configuration
*3: DO channel: FALSE AO channel: 0.0 [mA]
*4: This works if dangerous failure (DO module channel is fixed to ON) or failures requiring the protection of internal module (such as an overcurrent of AO module) occur. If you want to set the output shutoff switch to go on when dangerous failure requiring no protection of module occur, you can set the I/O parameter of the output module channel.

Considering application actions on fault detection

- In the logic of NC input like ESD application, etc, setting "the input value at the error occurrence" to FALSE permits the application logic to handle a failure of the input module as a demand and perform actions like shutdown.
- For De-energize To Safe (DTS) output in ESD application and so on, it is necessary to set the I/O Parameters for Output value at fault in order that the process is in a shutdown state when all the outputs become the Output value at fault.
- When a failure of an output module occurs, a shutdown action for different related output modules is required depending on the process. In this case, it is necessary to create the application logic to shut down the output of different related modules when the output channel data status changes into a BAD state.

SEE ALSO For more information about example of creation for an application logic which monitors the channel data status and performs a shutdown, refer to:

A4.2, “Shutdown due to channel failure” on page A4-7

For more information about procedures for setting I/O parameters, behavior of SCS upon occurrence of errors, and procedures for recovery, refer to:

G2., “Operations and recovery procedures during the SCS error occurrence” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Setting of parameters of I/O modules

This section explains the precautions to be taken when setting the parameters of an I/O module. When performing RS original engineering, you can set parameters by using I/O Parameter Builder. When performing I/O list engineering, you can specify the parameters by using AD Organizer.

Parameters of I/O modules include the specifications of actions on error detection. It is necessary to be careful when setting them.

Issues to consider when setting the parameters (by channel) of the Analog Input module (SAI143/L1AI143)

- Select two-wire or four-wire according to field devices for "Field power supply diagnosis." For all specified items for detection, the default settings are recommended.

- When two-wire or four-wire for Field power supply diagnosis is set, specify it to set pins on hardware for the current input module. In the case of different settings in the "Field power supply diagnostics" and hardware pins, the module will not start due to diagnosis error.

SEE ALSO For more information about parameters for each channel of the analog input module for current/voltage, refer to:

Appendix 1.3.2, “Settings for the AI channel” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Issues to consider when setting the parameters (by channel) of the Analog Input module (SAT145/L1AT145, SAR145/L1AR145)

Enter the Input Value at Fault, Threshold of the IOP (High) level, and the Threshold of the IOP (Low) level as % units. If the input signal is engineering data, convert the setting value from engineering data to a % unit based on the upper and lower range values.

Setting (%) = (Setting in engineering data - lower range value) / (upper range value - lower range value) x 100

Example:

When you select [Type K] for the Signal Conversion and select [C] for the Engineering Unit.

- The permissible range is -200 to 1200 deg. C.
- To set the Input Value at Fault to 900 deg. C, set (900 + 200) / (1200 + 200) x 100 = 78.6 %.

IMPORTANT

You must use the upper and lower range values of the I/O Parameter Builder. Be careful to ensure that you do not use the upper and lower scale values of Tag Name Builder. If you have set the upper and lower scale values to between 0 and 800 deg. C in Tag Name Builder, ensure that you do not specify the Input Value at Fault as a % unit corresponding to between 0 and 800 deg. C.

SEE ALSO For more information about parameters for each channel of the analog input module for thermocouple/resistance temperature detector, refer to:

Appendix 1.3.2, “Settings for the AI channel” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Issues to consider when setting the parameters (by channel) of the Analog Output module (SAI533/L1AI533)

- If the short circuit detection level is not properly set when the wiring resistance exceeds 50 Ω, the short circuit may not be detected on outputting the "Output Value at Fault" or the Tight-shut value. To avoid this problem, set properly the short circuit detection level with reference to the following information.
- The "Output Value at Fault" is output to the field exactly as it was set when the fault is detected. If you want to do Tight-shut or Full-open on fault detection, set the same value as the Tight-shut value or the Full-open value to the "Output Value at Fault." If the Tight-shut value or the Full-open value is changed, check if the "Output Value at Fault" should also be changed.

SEE ALSO For more information about Tight-shut/Full-open settings for conducting HART communication, refer to:

A9., “HART communication” on page A9-1

For more information about short circuit detection level settings, refer to:

“■ Command Line” in Appendix 1.3.3, “Settings for the AO channel” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about parameters for each channel of the analog output module, refer to:

Appendix 1.3.3, “Settings for the AO channel” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Issues to consider when setting the parameters (by module) of the Digital Input module (SDV144/L1DV144)

- When the software filter is set to 1, if an ON state is detected twice in the scan timing of the DI module, the input value is fixed to ON, and its value referenced by the application logic.
- When a software filter is set to 0, the PV value is effected noise. Ensure that the software filter is not set to 0.
- In addition to the software filter for making the input values, the DI module also has a filter to make SOE events. The filter for verifying the SOE events will be disabled if the software filter is set to 0 (no filter). If set to 1 or a bigger value, the digital filter will be 10 ms filter.
- If you have set Automatically Delete Noisy Event to [Yes] and more events than the specified number occur in the channel in the specified event time, the extra events are automatically deleted.

SEE ALSO For more information about parameters for each module of the discrete input modules, refer to:

Appendix 1.3.4, “Settings for the DI channel” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Precautions for setting channel parameters of Digital Input module

- The Wiring Check Adapter (SCB100) and a sensor switch must be connected in parallel to detect disconnection. When the check adapter is not installed, specify "No detection."
- The following setting is recommended as the disconnection detection value.
  - Specify "No detection of disconnection" (default) for NC (Normally Close) input.
  - Specify "Detection of disconnection" (Wiring Check Adapter is required to be installed.) for NO (Normally Open) input.
- Wiring Check Adapter(SCB110) and a sensor switch must be connected in series to detect a short circuit. When the check adapter is not installed, specify "No detection."
- For specifying the detection of a short circuit, the following settings are recommended. Specify "Detection of a short circuit" (default) for both of NC input and NO input.

  (Wiring Check Adapter need to be installed. For detecting both open and short circuits, while NO is selected, Wiring Check Adapters, both SCB100 and SCB110 are necessary.)
- In case of an NC input, to conduct a pulse test, the wiring check adapter (SCB110) and a sensor switch must be connected in series. When the input is NC and the check adapter is not installed, specify "No pulse test." In case of a NO input, a pulse test can be conducted without a check adapter.
- For a pulse test, the following settings are recommended.
  In case both of an NC input and a NO input, a pulse test should be conducted.(Default)

  (In the case of NC input, the wiring check adapter is required to be installed.)

SEE ALSO For more information about parameters for each channel of the discrete input module, refer to:

Appendix 1.3.4, “Settings for the DI channel” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Precautions for setting channel parameters of Digital Output module

- Set a proper value to the Output value at fault after carefully considering the operation of the application and the operation of the field in error condition.
- The following setting is recommended as the disconnection detection value.
  Specify "Detect Disconnection circuit" in both cases of DTS (De-energize To Safe) output and ETS (Energize To Safe) output (Default).
- For a pulse test on OFF, the following setting is recommended.
  Specify "Pulse Test" in both cases of DTS output and ETS output (Default).
- For a pulse test on ON, the following settings are recommended.
  - Specify "No pulse test" in the case of DTS output (Default).
  - Specify "Pulse Test" in the case of ETS output.

SEE ALSO For more information about parameters for each channel of the discrete output module, refer to:

Appendix 1.3.5, “Settings for the DO channel” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

A3. Creating an application for monitoring the status and process state of the SCS

The SCS status and process state can be monitored from SENG and HIS in CENTUM Integration structure.

In CENTUM Integration structure, HIS can monitor both CENTUM System and SCS.

It is possible to monitor faults in the system by annunciator panel.

This section describes the requirements for creating applications for monitoring process and system.

A3.1 Monitoring SCS status

The status of SCS can be checked on SENG and HIS. When a fault occurs in SCS, the fault can be located in a visual way.

Monitoring I/O data and application logic data

User can monitor I/O data and application logic data from SENG, HIS and external equipment via Modbus.

Notification of the SCS status with an external alarm panel

Creating the application logic of SCS makes it possible to output the data about SCS fault status to the external alarm panel so that the fault status can be informed to an operator.

It is recommended to put such alarm panel in a place where the operator can see the panel for continuous monitoring in order to monitor faults occurring in hardware of SCS.

When the occurrence of a fault in hardware is recognized on the external alarm panel, the detailed information on the fault is confirmed on the Diagnostic Information Window in SENG.

The following example shows the application logic to inform the fault status to the external alarm panel in SCS using a system function block.

An example of using the SYS_DIAG to output SCS fault status to an external Alarm panel

Diagnostic Information FB (SYS_DIAG) detects all system faults except user's operation mistakes. The following example shows how to use the SYS_DIAG to output system faults, I/O and control bus-related faults to an external Alarm Panel.

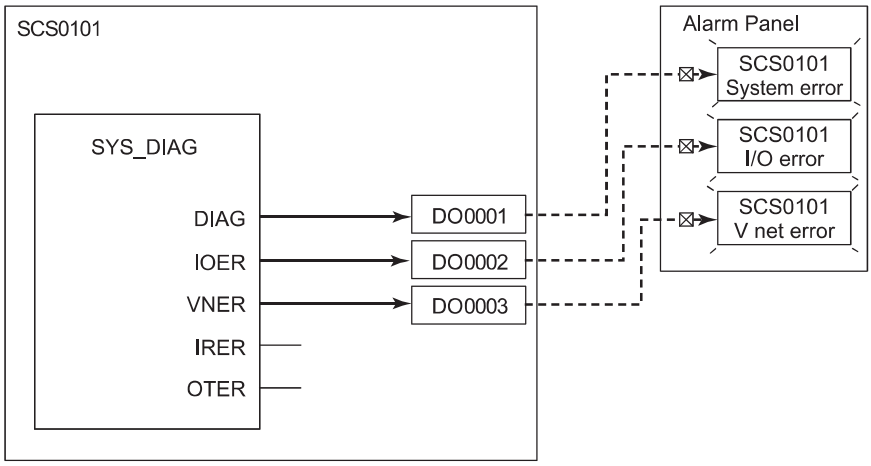

Figure A3.1-1 Example of the logic to output SCS fault status to external Alarm panel

SEE ALSO For more information about function details of the SYS_DIAG system function block, refer to:

11.7, "SYS_DIAG (diagnostic information output)" in POU Reference Manual (IM 32P03B20-01EN)

A3.2 Monitoring process with process alarm message and annunciator message

In CENTUM Integration configuration, information on a process state can be notified to HIS as a process alarm or annunciator messages from the application logic of SCS.

The process alarm and annunciator messages can be used as a pre-alarm before generating a trip in SCS. In the CENTUM system, they inform the operator that the appropriate action should be taken in the plant.

The following example shows the application logic to output a process alarm and annunciator message.

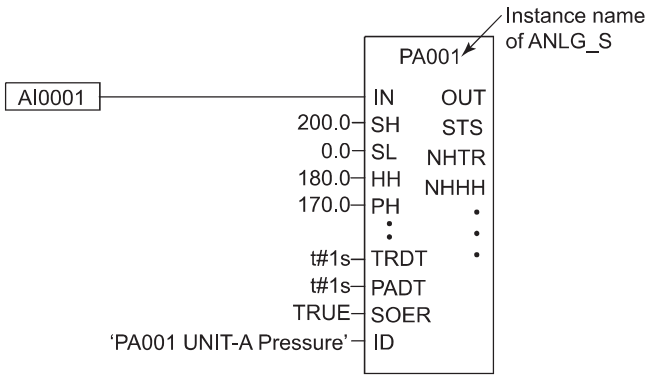

Figure A3.2-1 Example for the output of process alarm of analog input to HIS

Creating such an application logic and then setting a tag name for the instance name generates a mapping block for CENTUM integration. The mapping block allows alarm for the Analog input value (AI001) to be displayed as process alarm on HIS. Note that the alarm setting value (HH/PH/PL/LL) cannot be changed on HIS.

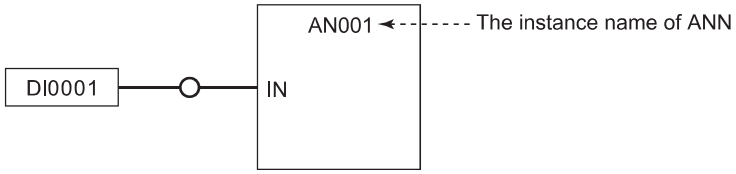

Figure A3.2-2 Example for the output of annunciator message to HIS

If you create ANN for such an application logic and define the annunciator message string in the %AN mapping element for the ANN instance name, the annunciator message appears on HIS.

A3.3 Fire and gas device application

This section gives an overview of the functions for fire and gas device applications, the SCSs that support the functions, and the function blocks for fire and gas devices.

Overview of functions for fire and gas device applications

ProSafe-RS has functions for applications that use fire and gas devices such as smoke detectors, heat detectors, gas detectors, and flame detectors.

For smoke and heat detectors, a device reset function and a function that suppresses alarms during device reset are provided, which are implemented by using the function blocks developed for them. For gas and flame detectors, a function block which has the function to manage the operation state of the device is provided.

SCSs that support the functions for fire and gas device applications

Each function for fire and gas device application functions is supported by the following types of SCS.

Table A3.3-1 SCSs that support the functions for fire and gas device applications

Function	Type of SCS supporting the function
Device reset function (N-IO)	S2SC70
Device reset function (FIO)	S2SC70, L1SC70, SSC60 , SSC50 , SSC57
Alarm suppression during device reset	S2SC70, L1SC70, SSC60 , SSC50
Function block for fire and gas devices	S2SC70, L1SC70, SSC60, SSC50 , SSC57

Function blocks for fire and gas devices

There are the two following types of function blocks for fire and gas devices:

- HSDTR (analog input function block for smoke and heat detectors)
  HSDTR is a function block for smoke detectors and heat detectors. We recommended that you use HSDTR when using the device reset function. If you create an application logic using HSDTR, you can reset a smoke or heat detector by manipulating the mapping block of HSDTR from the instrument faceplate on HIS, for example. It is also possible to suppress the system alarms for occurrence and recovery of channel errors that accompany reset, and suppress the IOP process alarm.
- GASDTR (analog input function block for gas and flame detectors)
  Even after detecting a field error, when the field returns to the normal state, gas and flame detectors output normal values according to the status of the field. For this reason, an external reset is not required. Some types of gas and flame detectors notify their own operation status by sending a value outside the range of process values. GASDTR has a function to manage such device operation status in three levels.

An override can be performed for HSDTR and GASDTR. We recommend that you perform an override in combination with the override function block (OVR_* and GOV_*).

SEE ALSO For more information about details of HSDTR, refer to:

5.17, “HSDTR (analog input function block for smoke and heat detectors)” in POU Reference Manual (IM 32P03B20-01EN)

For more information about details of GASDTR, refer to:

5.18, “GASDTR (analog input function block for gas and flame detectors)” in POU Reference Manual (IM 32P03B20-01EN)

A3.4 Device reset function for smoke detectors and heat detectors

With smoke detectors and heat detectors (hereinafter referred to as devices), there is a type of device that retains the analog output as a value indicating the occurrence of an error when a field-side error is detected. With such device, unless the device is reset by turning the power OFF/ON, the status where the value indicating the occurrence of an error is retained will not be released. ProSafe-RS is equipped with a module that supports the function of resetting devices by once cutting off and then resuming the supply of power to the devices. By using this module, you can reset 2-wire type devices without setting up an external circuit. This function is referred to as the device reset function. However, in the case of a device powered from the outside, you cannot cut off/reconnect the power supply using this function. You need to use an external circuit.

This function is supported with both FIO and N-IO types of modules.

The reset can be performed with one of the following methods:

- From a window such as the instrument faceplate of HIS when using a CENTUM integration configuration
- From hardware such as an external button switch

The following figure shows a conceptual diagram of implementing a reset from HIS by using the FIO module.

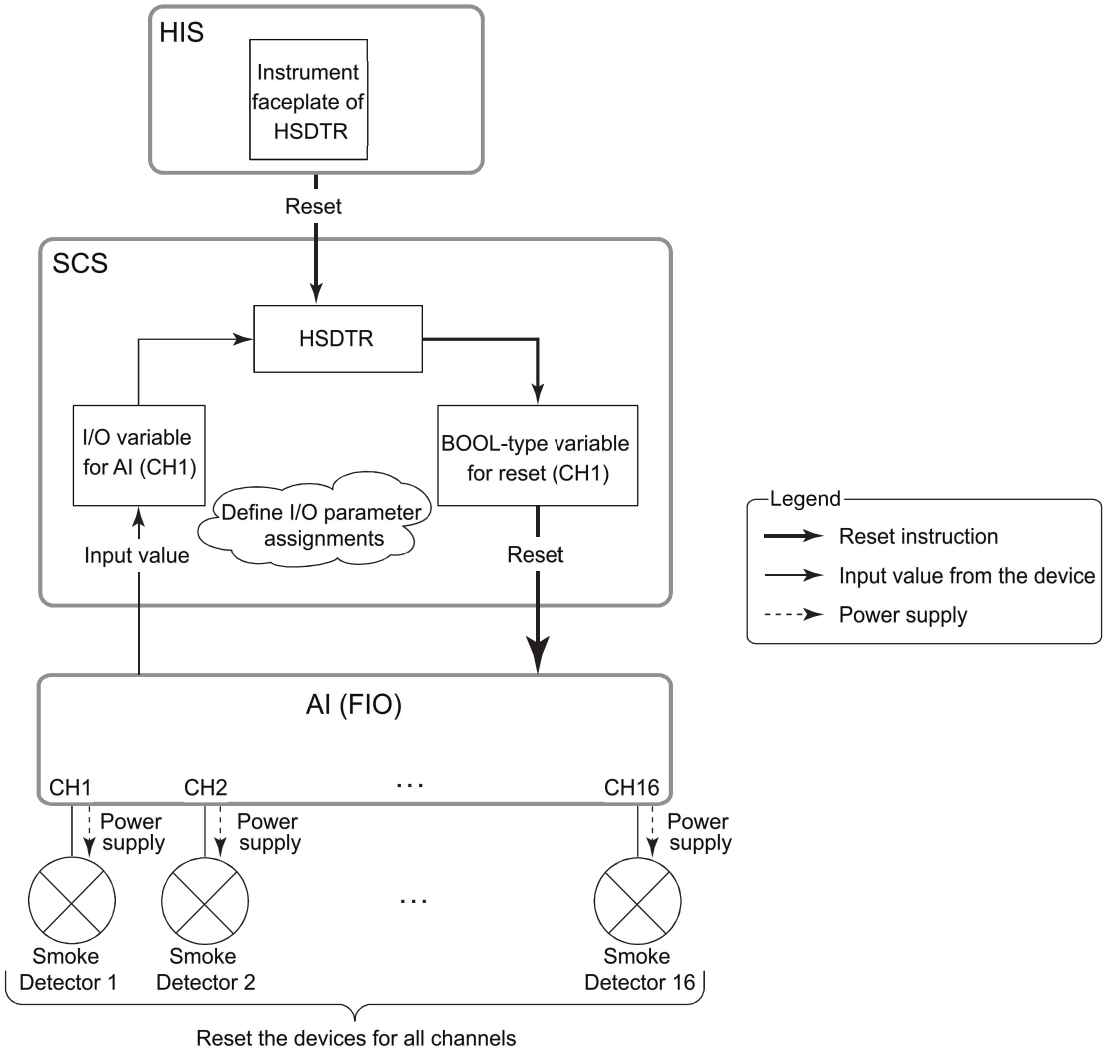

Figure A3.4-1 Example of implementing a reset from HIS by using the FIO module

TIP

This function does not apply to devices powered from outside. You must use an external circuit to reset such devices.

A3.4.1 Device reset function with FIO

This section explains the types of FIO modules supporting the device reset function, the behavior thereof, and precautions.

Modules subject to the device reset function

FIO modules that support this function are style S4 and later of SAI143-S and SAI143-H, and L1AI143-S and L1AI143-H. For SAI143-S and SAI143-H, the devices cannot be reset with modules earlier than style S4. For dual-redundant modules, make sure the both modules are style S4 or later. Only 2-wire type devices connected to the channels of 2-wire type settings are subject to this function.

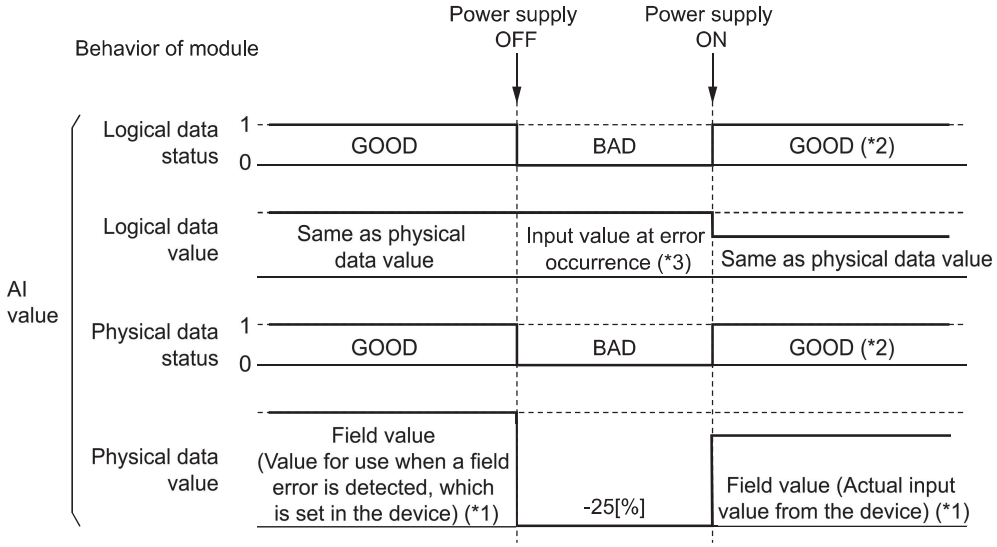
TIP

If a module earlier than style S4 of SAI143-S or SAI143-H is used, the following behavior will take place when Device Reset Function (per module) is set to the I/O parameter of the module:

After startup of the module, a system alarm (No. 0749) will be generated, indicating that an error was detected in self-diagnosis. Also when the reset operation is performed, the system alarm for a self-diagnosis error (No. 0749) will be generated. The device will not be reset.

Behavior of reset

- When the reset operation is performed, all devices connected to the channels of the corresponding module will be subject to the reset.
- When the reset operation is performed, the module will stop, and therefore the supply of power to the devices will also be cut off. At this time, the logical data values on all input channels become the input value at error occurrence, which is set with the I/O parameter, and the data status will become BAD. Upon startup of the module, the supply of power to the devices is resumed and the devices will also start up.
- When the reset operation is performed, the input behavior of the module and the generation of alarms will follow the behavior of IOM Fail/Recover.
- When the modules are in dual-redundant configuration, the both modules will Fail/Recover. The control rights will not switch. When the modules stop, the ACT lamp of both modules will turn off.



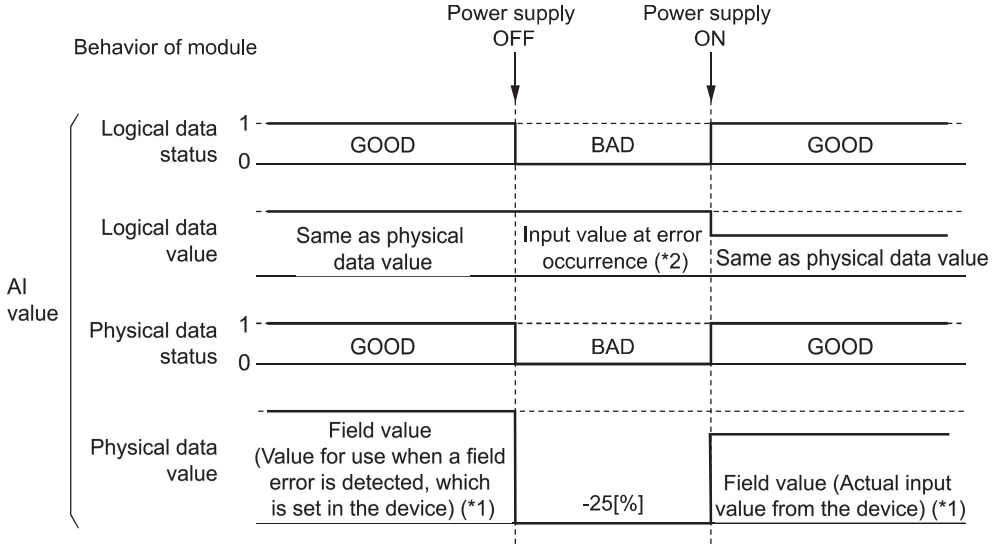
Behavior when channels of 2-wire and 4-wire settings are mixed

With SAI143-S/L1AI143-S and SAI143-H/L1AI143-H, behavior of the input of all channels is the same even when channels of 2-wire and 4-wire settings are mixed. However, because power is supplied externally with 3-wire and 4-wire devices connected to a 4-wire setting channel, it will not be possible to turn such devices OFF/ON by using the device reset function.

Change of input value upon reset operation: FIO

The input behavior of the module after turning the power supply OFF is the same as the behavior of IOM Fail/Recover. The data status will change in accordance with the IOP/TRNS detection specification set with the I/O parameters of the module. The following figures show examples where a device reset is performed after the field has recovered the safe state.

- When set to detect IOP/TRNS



*1: The specific values vary with each device.
*2: The status changes according to whether the field value exceeds or falls below the upper or lower limit of IOP/TRNS.
*3: This figure assumes that [Input Processing at Fault] is set to [Hold] for the I/O parameter.

Figure A3.4.1-1 Input value from the device when set to detect IOP/TRNS

- When set to not detect IOP/TRNS

  Because of the setting to not detect IOP/TRNS, the data status after the supply of power is resumed is GOOD.

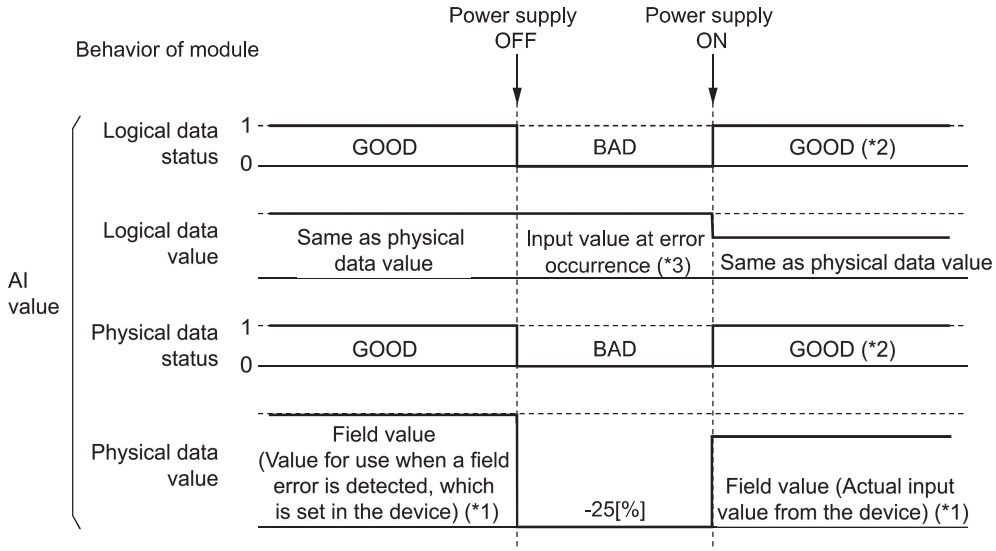
*1: The specific values vary with each device.
*2: This figure assumes that [Input Processing at Fault] is set to [Hold] for the I/O parameter.

Figure A3.4.1-2 Input value from the device when set to not detect IOP/TRNS

A3.4.2 Device reset function with N-IO

The device reset function can be used with devices connected to AI channels with 2-wire settings of the N-IO module S2MMM843. Reset of devices can be performed per channel.

IMPORTANT

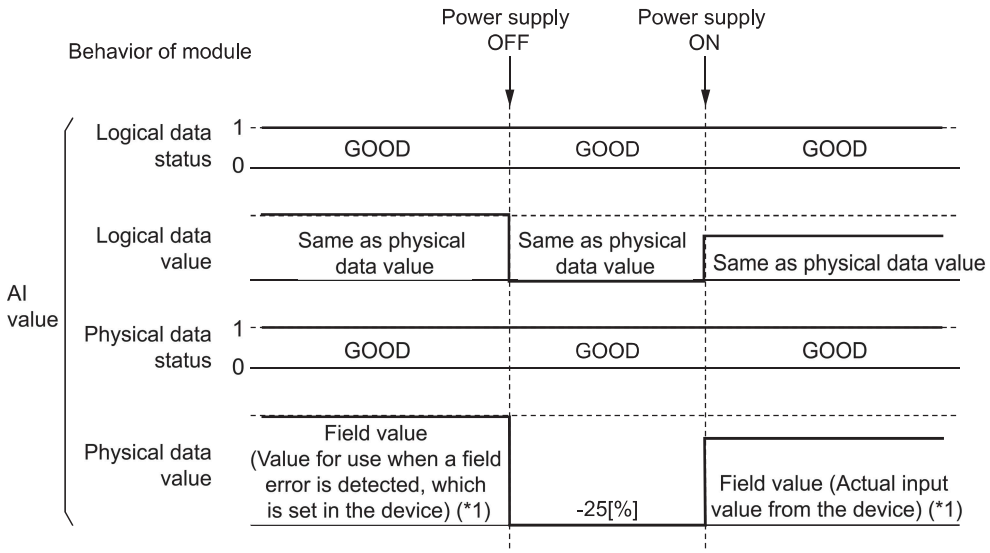


For devices with an intrinsic safety barrier, the barrier card powers 2-wire type devices. You must use an external circuit to reset such devices.

Change of input value upon reset operation: N-IO

The input operation for the AI value that is connected to devices varies depending on whether or not it is set that IOP/TRNS is detected with the I/O parameters of the module.

The following figures show the input values from the devices when IOP/TRNS is set to be detected or when it is not. The following figures show examples where a device reset is performed after the field has recovered the safe state.



- When set to detect IOP/TRNS

*1: The specific values vary with each device.
*2: The status changes according to whether the field value exceeds or falls below the upper or lower limit of IOP/TRNS.
*3: This figure assumes that [Input Processing at Fault] is set to [Hold] for the I/O parameter.

Figure A3.4.2-1 Input value from the device when set to detect IOP/TRNS

- When set to not detect IOP/TRNS

*1: The specific values vary with each device.

Figure A3.4.2-2 Input value from the device when set to not detect IOP/TRNS

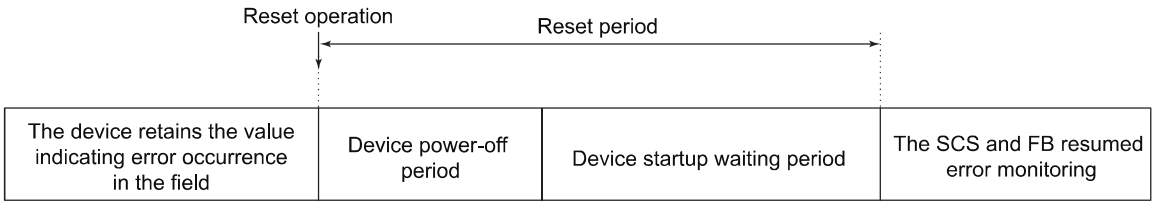
TIP

The behaviors of logical data status and logical data value from when the power supply is turned off until the power supply is turned on differ from those of FIO. With FIO, the power supply is turned off and on in module units, therefore it is accompanied by IOM Fail/Recover actions. With N-IO, the power supply is turned off and on for each channel.

SEE ALSO

For more information about IOP, TRNS, refer to:

Appendix 1.3.2, “Settings for the AI channel” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)



A3.4.3 Device reset function and alarm suppression during device reset

With the device reset function, multiple devices can be reset simultaneously. Also, the display of messages and the sounding of buzzers for system alarms and process alarms generated when a device is in the reset status can be suppressed.

- The reset group ID is an identifier for handling all the channels and HSDTR that are reset at the same time as being in the reset status. SCS manages the reset operation of multiple devices by reset group ID. Assign the same reset group ID to devices that are to be reset at the same time.
- The function to suppress alarms during device reset can be used in the following cases. However, process alarms can be suppressed only when using HSDTR.
  - When using the device reset function of FIO and the N-IO module
  - When using an external reset circuit
  - When using HSDTR
  - When creating an application logic without using HSDTR

■ Definition of reset period

The time from when the reset process is started up to when the power of the device is turned OFF/ON and SCS and FB resume monitoring of errors is referred to as the reset period. The definition of the reset period is shown in the following figure.

Reset period = Device power-off period + Device startup waiting period
Device power-off period: The time period during which the power supply to the device is stopped
Device startup waiting period: The time from when the power supply to the device is started until the SCS and FB resume error monitoring

It may take about one or two scan periods of time from when a reset operation is performed until the device is powered off.

Figure A3.4.3-1 Reset period

The Device Power-Off Period and Device Startup Waiting Period are values set by the user to suit the actual devices.

SEE ALSO For more information about how to set the device power-off period and device startup waiting period, refer to:

"■ Setting the I/O parameters" on page A3-14

■ Behavior of alarm suppression during reset period

When using alarm suppression during device reset, SCS and HIS will behave in the following manner during the reset period:

- When the occurrence of or recovery from an error is detected during the reset period, SCS notifies HIS with a system alarm to which an instruction to suppress messages is attached.

- HIS follows the instruction from SCS and suppresses the display of messages and the sounding of buzzers for system alarms.
- SCS only notifies HIS of the suppression of messages and still detects the occurrence of and recovery from errors during suppression.
- The mapping block of HSDTR uses the function of AOF to suppress the display of process messages and the sounding of buzzers during the reset period.

IMPORTANT

When a device is reset while in the status where a system alarm for No. 0081 IOM Fail or No. 4125 Channel Error has been generated, the alarm will remain displayed even if such error is recovered during the reset period. Because of still being in the reset period, a system alarm for recovery will not be displayed.

After the reset period ends, use the SCS Status Display view of HIS to confirm the status of the I/O module and channel. If the status has been recovered to the normal status, manually delete the system alarm for No. 0081 IOM Fail or No. 4125 Channel Error.

In the following cases, alarms that were suppressed during the reset period will be sent again after the reset period ends:

- System alarms and process alarms that were generated during the reset period but were not recovered by the end of the period will be sent again with the next scan after the reset period has ended.
- In order for process alarms to be sent again, setting is required with SCS Constants Builder.

SEE ALSO For more information about how to set SCS Constants Builder, refer to:

"■ Setting the SCS constants" on page A3-14

Display of alarms subject to alarm suppression

The types of alarms suppressed during the reset period are as follows:

Table A3.4.3-1 Type of alarm subject to suppression

System alarms (*1)	Process alarms
• No. 0081 IOM Fail (*2) • No. 0082 Recover (*2) • No. 0459 IOM In Service (*2) • No. 0460 IOM Out Service (*2) • No. 4125 Channel Error • No. 4126 Channel Recover	All process alarms of the mapping block of HSDTR performing the reset process

*1: These alarms, even when generated during the reset period for a reason other than that of the reset, will be subject to suppression.
*2: Alarms subject to suppression only when the device reset function (per module) is enabled using SAI143/L1AI143.

With HIS, the display of alarms subject to the function are suppressed. This is the same with CAMS for HIS. With CAMS for HIS, historical data subject to suppression is displayed as events. In the instrument faceplate corresponding to the mapping block of HSDTR, AOF is displayed and tag marks are displayed in blue.

System alarms subject to alarm suppression are communicated to the OPC clients as logging alarms. Whether logging alarms are displayed will depend on the settings of the OPC client.

The following items will not be affected by the alarm suppression function:

- Historical message report window of HIS

- Alarm status
- SCS station status display view of HIS
- SOE viewer
- SCS maintenance support tool of SENG
- Diagnostic Information window of SENG
- System function block SYS_IOALLST

Behavior of HSDTR

The instance of HSDTR receiving the reset request will behave as follows during the reset period:

- System alarm No. 4207 for notifying the reset operation will be generated.
- TRUE (Occurred) is output to POFF for the specified device power-off period and once the device power-off period has elapsed, FALSE is automatically output.
- With the instance receiving the reset request and all instances to which the same reset group ID as that instance has been set, HTRP will be FALSE during the reset period. STS will be GOOD.

The mapping block of HSDTR will behave as follows with HIS during the reset period:

- A value according to the input value from the field will be reflected onto the alarm status of the mapping block.
- The block status of the mapping block will become RST (reset status).
- When alarm suppression during device reset is enabled, the display of messages and the sounding of buzzers for process alarms are suppressed.

IMPORTANT

In order to link the behavior of field devices with the behavior of FB, match the value of the argument HH of HSDTR with the setting value of the devices. HH is an argument for specifying the HI trip level.

SEE ALSO For more information about details of HSDTR, refer to:

5.17, “HSDTR (analog input function block for smoke and heat detectors)” in POU Reference Manual (IM 32P03B20-01EN)

A3.4.4 Engineering regarding the device reset function and alarm suppression during device reset

In order to use the device reset function and alarm suppression during device reset, perform settings with SCS Constants Builder and set the I/O parameters for the modules and channels.

■ Setting the SCS constants

Perform the following settings with SCS Constants Builder when using the device reset function and alarm suppression during device reset.

Perform the settings that decide the reset period. The reset period is a parameter used by the SCS when performing the reset process of devices and when suppressing alarms during the reset period. As this value is decided per station, decide the value in consideration of the behavior of all field devices that will actually be used.

- Device power-off period
  Set the time for which TRUE is output to the POFF of HSDTR. Set a time by which all devices connected to the corresponding station will surely come to a stop.

  Set the value to [Device Power-Off Period] of the [SCS] tab.
- Device startup waiting period
  Set the time from when the supply of power to the device is resumed to when the device completes normal startup. Set a time that suits the device that takes the greatest amount of time for startup among the devices connected to the corresponding station.

  Set the value to [Device Startup Waiting Period] of the [SCS] tab.

In order to use alarm suppression during device reset, under the [SCS] tab, set [Alarm Suppression During Device Reset] to [Enable].

To use HSDTR and resend process alarms not recovered during the reset period, under the [Communication] tab, set [Alarm Notify Action when AOF Released] to [Yes].

SEE ALSO For more information about definition of reset period, refer to:

"■ Definition of reset period" on page A3-11

■ Setting the I/O parameters

The following is a setting example of the I/O parameters with I/O list engineering. The necessary settings are different depending on the modules being used and the function to be used. The following table shows the relationships between the functions to be used (column) and necessary setting items (row).

Table A3.4.4-1 Setting items necessary for use of each function for smoke detectors and heat detectors

	Device reset function	Alarm suppression during device reset	HSDTR
I/O parameter of the module	Setting required with SAI143/L1AI143	-	-
BOOL-type variable for reset to the channel	Setting required with SAI143/L1AI143 and S2MMM843	Setting required with SAI143/L1AI143, SAV144/L1AV144, and S2MMM843	Setting required with SAI143/L1AI143, SAV144/L1AV144, and S2MMM843
Reset group ID for the channel	Setting required with SAI143/L1AI143 and S2MMM843	Setting required with SAI143/L1AI143, SAV144/L1AV144, and S2MMM843	Setting required with SAI143/L1AI143, SAV144/L1AV144, and S2MMM843

Setting procedures

- Setting the I/O parameter of the module
  With IOM Definition Editor, set [Device Reset Function (per module)] of the module's I/O parameter item to [Enable].
- Setting the BOOL-type variable for reset to the channel
  With Safety I/O Editor, set a BOOL-type variable for reset to [Device OFF-ON Variable Name] for the channel to which the device subject to the reset will be connected. For this BOOL variable, create application logic so that the device power OFF/ON command is input from the function block.
- Setting the reset group ID for the channel
  With Safety I/O Editor, set the reset group ID to [Reset Group ID] of the channel to which the device subject to the reset will be connected. Set a value in the range of 1 through 1000.

Precautions when setting the reset group ID

- When there are multiple devices to be reset at the same time, set the same reset group ID to all channels to which such devices are connected. This is necessary in order to handle channels to be reset at the same time as being in the reset status.
- Even for channels for which devices will be reset independently, be sure to set a reset group ID that is unique within the range of the same SCS.
- When using HSDTR, set the reset group ID that you set as the I/O parameter for the connected channel to the argument RID of the HSDTR that corresponds to the device.

TIP

Set the reset group ID of the channel to 0 when not using alarm suppression during device reset nor HSDTR. The default value is 0.

Example of application logic

The following figure shows an example of application logic where HSDTRs are used to monitor and reset the smoke detectors or heat detectors that are connected to all channels of SAI143. The device reset function and alarm suppression during device reset are used. The application logic should be created as follows:

- The BOOL-type variable for reset is connected to POFF of HSDTR.
- The same reset group ID as that which has been set to CH1 through CH16 of the module is set to RID of HSDTR01 through HSDTR16. In this example, the reset group ID is set to 1.

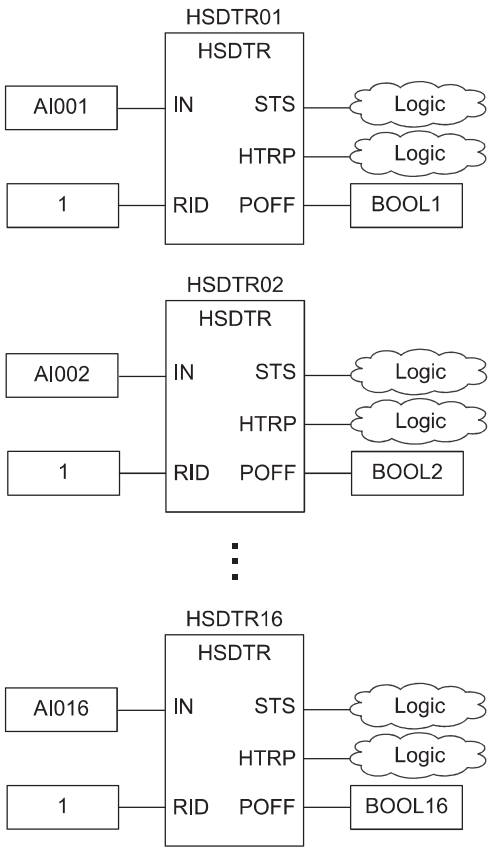


Figure A3.4.4-1 Example of application logic for monitoring and resetting smoke and heat detectors

In this example, Device Power-Off Period is set to 3 seconds and Device Startup Waiting Period is set to 20 seconds. The reset period is 3 + 20 = 23 seconds.

Behavior of the example application logic

This section explains the behavior from when a field-side error is detected with HSDTR01 that is connected to CH1 of SAI143, followed by starting of a device reset after recovery of the safe state in the field, up to when the reset period ends. The following behavior of 1 through 3 corresponds to 1 through 3 shown in the top part of the following figure “Behavior from error occurrence on field-side to the end of the reset period.”

1. With HSDTR01, when the status where the value of OUT is larger than HH continues for at least the time specified with TRDT, TRUE is output to HTRP. The status of HTRP being TRUE will remain latched until the reset process is started.

   It is assumed that at this time, with HSDTR02 through HSDTR16, OUT is equal to or less than HH in the normal status and FALSE is being output to HTRP.

2. The following behavior will take place during the reset period:

   - HSDTR01 generates a system alarm for notifying the reset operation.
   - HSDTR01 outputs FALSE to HTRP.
   - HSDTR01 starts the testing of whether the conditions for FALSE are established with HTRA and reflects the results thereof onto the alarm status of the mapping block. If the device has a function to retain the value indicating a field-side error, TRUE is output to HTRA because the conditions for FALSE are not established with HTRA.
   - Instance HSDTR01 receiving the reset request and instances to which the same reset group ID as this instance has been set (HSDTR02 through HSDTR16) will output GOOD to STS.

- HSDTR01 will communicate an instruction to turn the power of the device OFF/ON to the input module through a BOOL-type variable for reset. As the reset will be performed per module, the power of the devices connected to CH2 through CH16 will also be turned OFF/ON.
  As the time for shutting off the power supply to the device is the Device Power-Off Period, this is 3 seconds.
- During the reset period, process alarms are suppressed for instance HSDTR01, which receives the reset request, and the instances (HSDTR02 through HSDTR16), which have the same reset group ID as HSDTR01. Also, system alarms for channels to which the same reset group ID has been set will also be suppressed. In this example, the duration is 23 seconds from the start of the reset.
- HSDTR01 through HSDTR16 will not perform testing of whether the conditions for TRUE are established with HTRP. HSDTR01 through HSDTR16 will constantly output TRUE (GOOD) to STS.
- When the channel is set to detect IOP/TRNS, until the output of the device exceeds the TRNS- detection value, an input value at error occurrence will be input as the logic data value. Also, at the same time, BAD will be input as the logic data status and BAD will be output to STSR. When the output value of the device exceeds the TRNS- detection value, OUT will become the output value of the device.

3. When the reset period ends, HSDTR01 through HSDTR16 will resume the testing of whether the conditions for TRUE are established with HTRP and output the result to HTRP. HSDTR01 through HSDTR16 will again output IN.status to STS.

TIP

When the status where the input to the channel of SAI143 is equal to or less than the TRNS- detection value continues even after the reset period has ended, a system alarm for Ch Fail and a process alarm for IOP will be sent again.

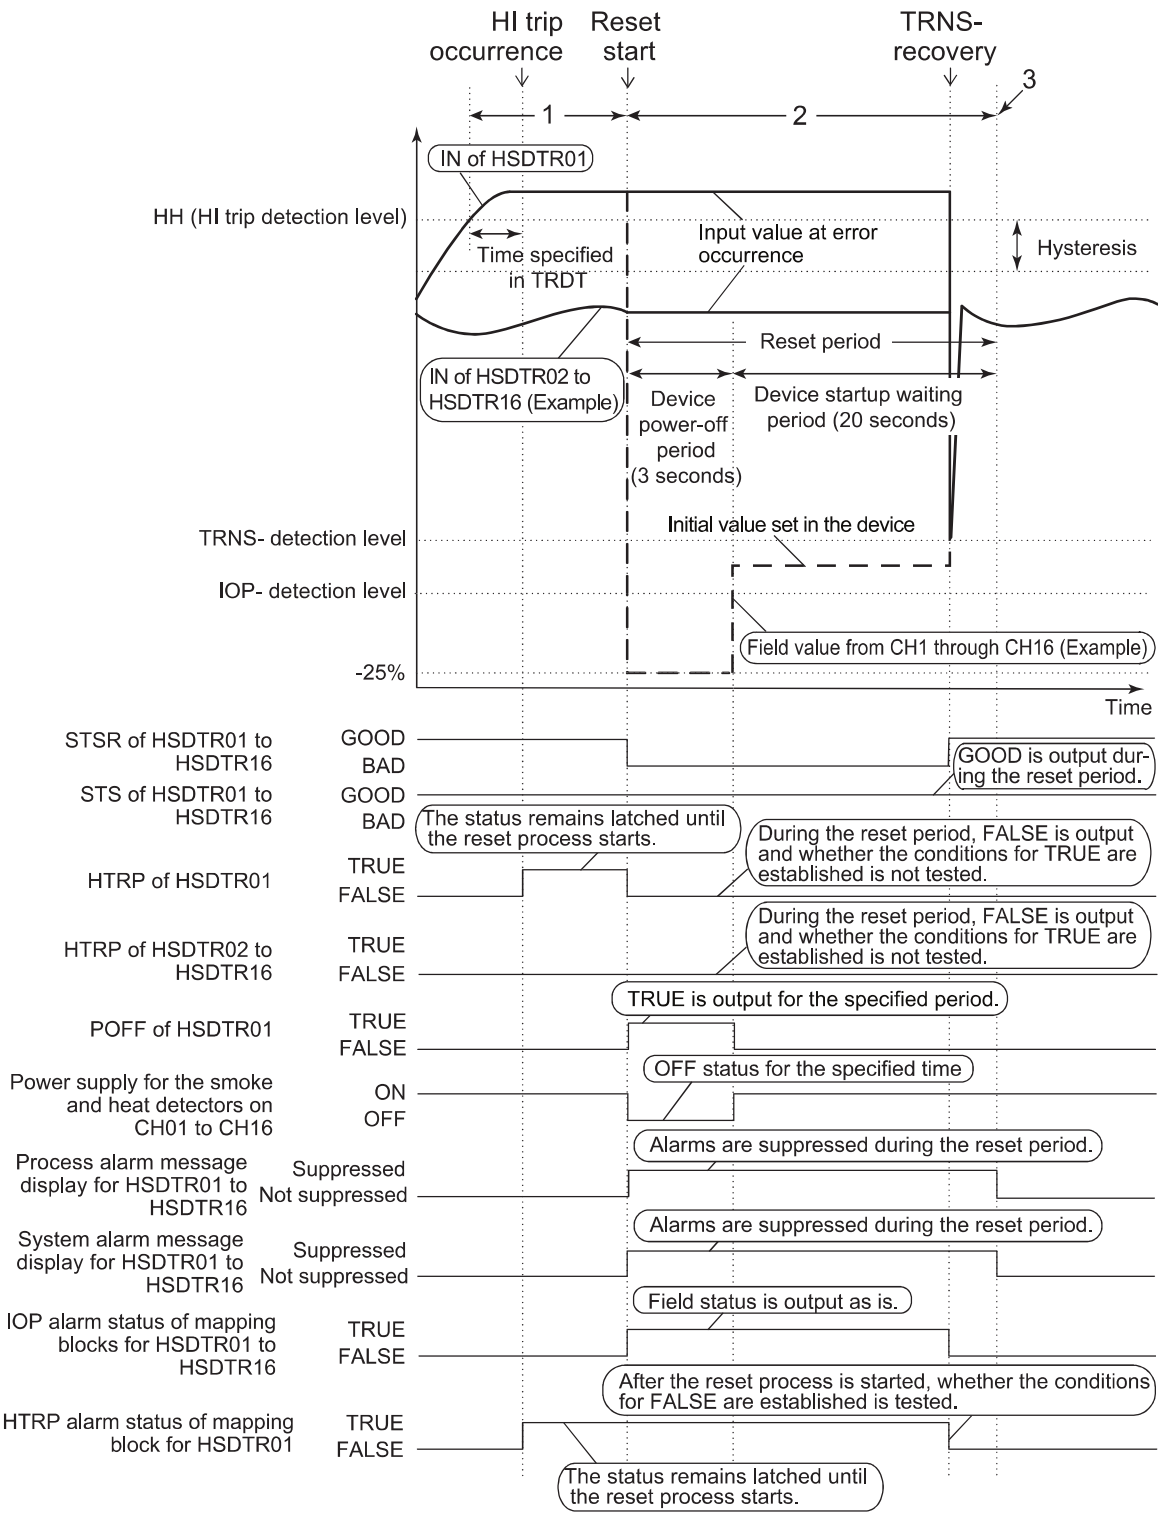

Figure A3.4.4-2 Behavior from error occurrence on field-side to the end of the reset period

A3.5 Utilization of override when performing maintenance of fire and gas devices

By combining the override function block with HSDTR or the GASDTR function block, it is possible to use the override function when performing maintenance of fire and gas devices. The following shows an example of HSDTR.

IMPORTANT

If a device connected to a channel of SAI143/L1AI143 is reset while override operation is being performed, the supply of power to the module will be shut off and then resumed. Because of this, all the channels of SAI143/L1AI143 having the channel that received the reset request will be reset. You must provide countermeasures in advance in order to prevent unintended operation of the devices that will be reset together.

Example of creating an application logic to enable override

Connect OVR_B to HSDTR.

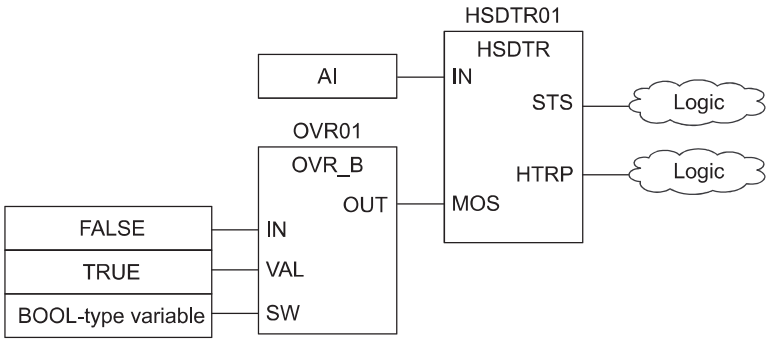

Figure A3.5-1 Example of connecting an override function block

Override operation procedure and behavior of the targets of operation

This section describes the procedure for override operation and the behavior of the targets of operation.

1. Set the BOOL-type variable connected to the SW of OVR01 to TRUE to allow override.
2. Start the override operation through OVR01 from the instrument faceplate on HIS.
   - System alarm No. 4115 for the override setting will be generated. The tag name displayed in the system alarm is the tag name defined for OVR01.
   - A process alarm indicating the override status will be generated from the mapping block of OVR01.
   - The alarm status of the mapping block of OVR01 will change to OVR.
   - The block status of the mapping block of HSDTR01 will change to OVR and process message No. 1405 for a change of the block status will be generated.
3. The behavior of HSDTR01 before and after the start of override is described as follows for each device status:
   - If override is started when the device is normal, HSDTR01 will continue to output FALSE to HTRP and TRUE to STS.

- If the device has detected a HI trip before override is started, HSDTR01 will output TRUE to HTRP and TRUE to STS. After override is started, HSDTR01 will output FALSE to HTRP and TRUE to STS.
- If the device has become faulty before override is started, the output values of HTRP and STS will depend on the type and fault status of the device and how the device has been engineered. However, after override is started, HSDTR01 will output FALSE to HTRP and output TRUE to STS.

TIP

During the override status, the value of HTRA and the alarm status of the mapping block of HSDTR01 will change in accordance with the value input to HSDTR01.

4. HSDTR01 and the mapping block thereof will behave in the following manner with operations during the override status:
   - When a device is removed for the purpose of replacement, etc. during the override status, the behavior will be as follows:
     - The input value to HSDTR01 will be an input value at error occurrence and the data status will change to BAD when the channel is set to detect IOP/TRNS. HSDTR01 will output FALSE to HTRP and output TRUE (GOOD) to STS.
     - The alarm status of the mapping block of HSDTR01 will follow the input value to HSDTR01.
   - When a reset operation is performed for HSDTR01 from the instrument faceplate of HIS or an external switch during the override status, the behavior will be as follows:
     - Due to being in the override status, HSDTR01 will continue to output FALSE to HTRP and output TRUE (GOOD) to STS.
     - During the reset period, HSDTR01 and the mapping block thereof will behave as they would during the reset period.
     - During the reset period, on HIS, the block status of the mapping block of HSDTR01 will be displayed not as OVR but as RST.
5. When maintenance of the device is finished, confirm that the input to HSDTR01 has recovered to the normal status and end the override operation through OVR01 from the instrument faceplate on HIS.
   System alarm No. 4116 for the cancellation of override will be generated.
6. Set the BOOL-type variable connected to the SW to FALSE to prohibit override.

A4. Example of creating an application logic

In ProSafe-RS, an application logic is created by combining programs, function blocks and functions.

Programs, function blocks and functions are referred as POU for a generic name. You can create POUs by using the Link Architecture View of SCS Manager and Multi-Language Editor, or by using iDefine. POUs that were created using iDefine cannot be edited in the Multi-Language Editor. Similarly, POUs that were created using the Multi-Language Editor cannot be edited in iDefine.

How to define POUs is described as follows:

- Program
  Implemented by combining variables, function blocks and functions
- Function block
  Implemented by combining input/output parameters, internal variables, function blocks and functions
- Function
  Implemented by combining input/output parameters and functions

SEE ALSO

For more information about precautions when creating an application, refer to:

A1., “Precautions for creating an application” on page A1-1

For more information about overview of POU, refer to:

1., “Overview of POU” in POU Reference Manual (IM 32P03B20-01EN)

For more information about creating an application logic by using iDefine, refer to:

iDefine User Guide (PR03076-MAN-970_01)

A4.1 Use of analog input value

Analog input modules include modules to handle current and voltage and modules to handle data from a thermocouple (TC) and Resistance Temperature Detector (RTD). Modules to handle input from TC or RTD hereinafter called TC/RTD input module.

Input signals input to the current/voltage input module are normalized and passed to the application logic in the form of 0.0-100.0% data. The user can convert this data into engineering data in the application.

Input signals input to the TC/RTD input module are passed directly to the application logic in the form of engineering data.

The following shows an example of application logic for comparison between an analog input value and a constant value.

Example 1: Application logic using the analog input values of the Current/Voltage Input module

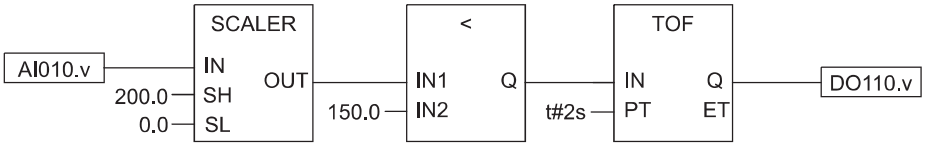

Figure A4.1-1 Example 1: Using current/voltage analog input value

In example 1 above, only Analog values are input. These are then converted to values in engineering units for comparison. If the Analog input value is larger than the reference value (150.0) for the specified period of time in Off Delay Timer (2 s), output is turned OFF.

Example 2: Application logic using the analog input values of the Current/Voltage Input module

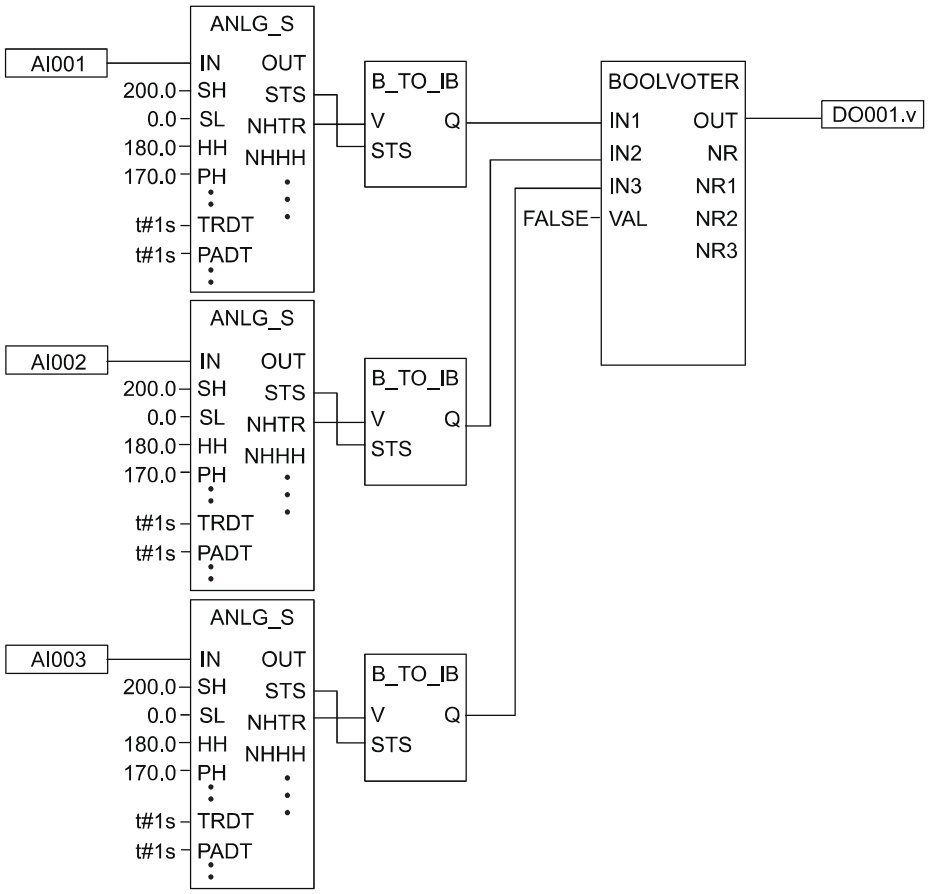

Figure A4.1-2 Example 2: Using current/voltage analog input value

In example 2, each of the three analog inputs is scale-converted by each ANLG_S and output. 2oo3 (2 out of 3) Voting result of the Trip outputs (NHTR) or a Fail-safe value is output as DO. Each ANLG_S produces a Trip output when the input value exceeds the Trip limit value for the period that is set in Off-Delay Timer (TRDT = 1 s in Example 2).

Example 3: Application logic using the analog input values of the Current/Voltage Input module

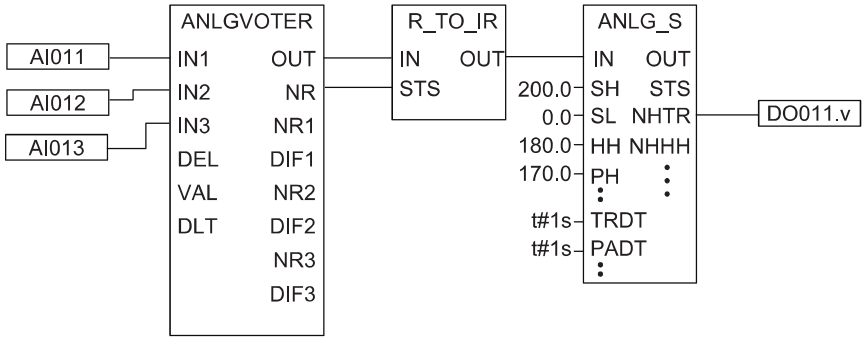

Figure A4.1-3 Example 3: Using current/voltage analog input value

The ANLGVOTER gets an intermediate value of analog inputs or a fail-safe value. The R_TO_IR converts the value to IO_REAL type and inputs it to the ANLG_S. The ANLG_S out-

puts the Voting result and Hi-Trip (NHTR). The ANLG_S produces a Trip output when the input value exceeds the Trip limit value for the period that is set in Off-Delay Timer (TRDT = 1 s in Example 3).

Example of application logic using the analog input values of the Thermocouple/Resistance Temperature Detector(TC/RTD)

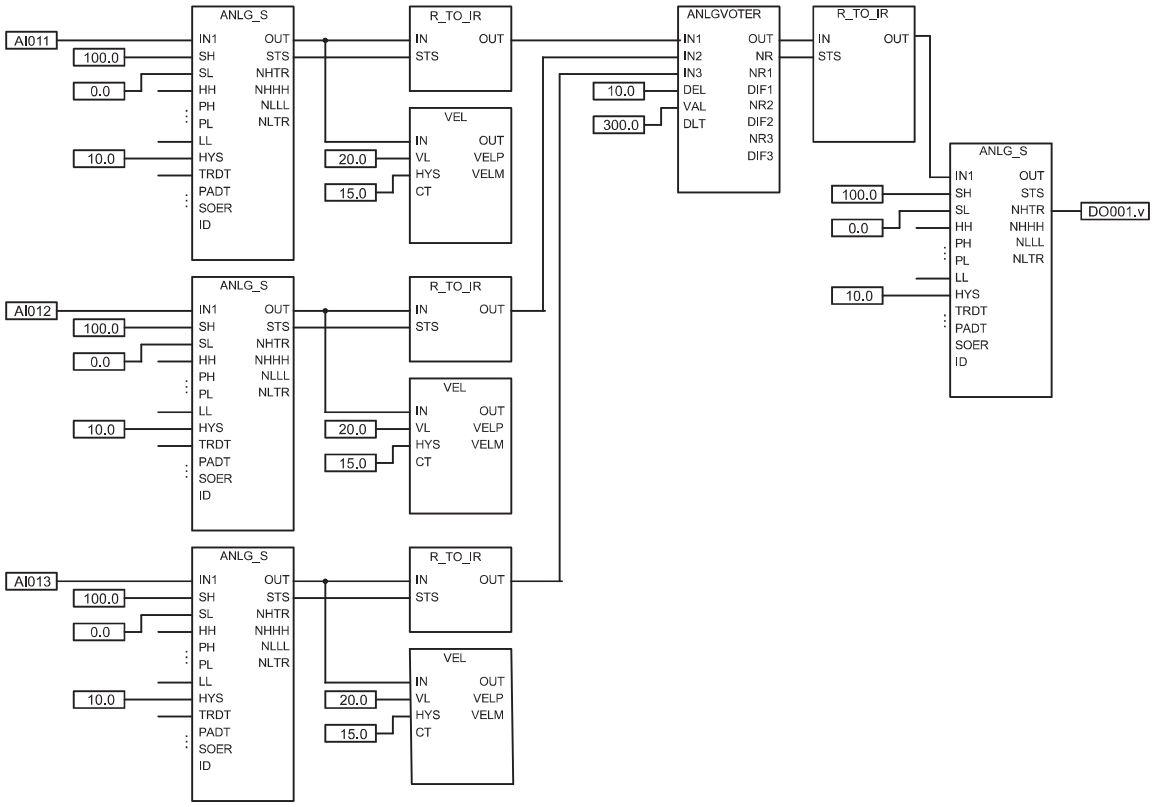

Figure A4.1-4 Example of application logic using the analog input values of the TC/RTD Input module

In the above logic example, the following processes are carried out.

1. Three analog inputs from TC/RTD input modules are each indicated by ANLG_S and the rate of change of each value is simultaneously monitored by VEL to ascertain whether the rate of change is exceeded from allowable range.
2. The intermediate values of the three types of data or the fail-safe values are obtained with ANLGVOTER.
3. The results are indicated by ANLG_S, monitored HI trip status and output to DO.

The input data from TC/RTD input module to ANLG_S is engineering data, which means that 100.0 and 0.0 are input to SH and SL respectively, and input to HYS is in the form of engineering data. The indicated value for ANLG_S (input value to VEL) is engineering data, and so VL and HYS of VEL should be input in engineering data. The same value should be converted to IO_REAL type using R_TO_IR. In R_TO_IR, there is no difference in the handling of input data, whether it is normalized or engineering data. The converted values are each input to ANLGVOTER and the median value or fail-safe value obtained, but since this value is also engineering data, the values input to DEL and VAL in ANLGVOTER are also engineering data. The value obtained is again converted to IO_REAL type using R_TO_IR and input to ANLG_S. In the same way, 100.0 and 0.0 are input to SH and SL respectively and the values input to HYS in the form of engineering data. The Voting result is indicated based on the input value and Hi-Trip (NHTR) is output to DO.

Precautions when using the analog input values from the Thermocouple/Resistance Temperature Detector (TC/RTD)

The input signal entered into the TC/RTD analog input module is passed to the application logic in the form of direct engineering data rather than normalized data.

Caution is required in the case of the ANLG_S, VEL, ANLG1OO2D, and ANLGVOTER, because there are differences in the way of making application logic whether the input data is engineering data or normalized data.

Case of ANLG1OO2D

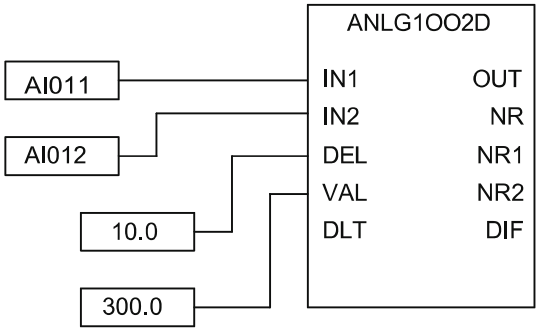

Figure A4.1-5 Example of ANLG1OO2D application logic

The data (AI011, AI012) from the TC/RTD input module is engineering data, and so the input values (IN1, IN2) and output value (OUT) are also engineering data. In this case, DEL and VAL are also entered as engineering data.

This means that, in the figure above, the values of DEL and VAL are specified as 10.0 deg. C and 300.0 deg. C respectively (if the engineering unit specified in I/O Parameter Builder is deg. C).

Case of ANLGVOTER

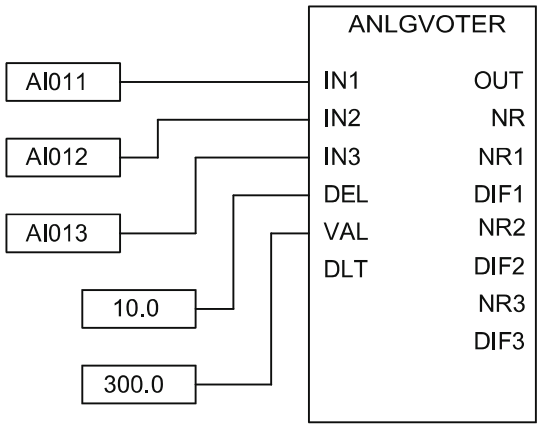

Figure A4.1-6 Example of ANLGVOTER application logic

As with ANLG1OO2D, if the input values (IN1, IN2, IN3) are engineering data, the output value (OUT) will also be engineering data.

DEL and VAL are also entered as engineering data.

Case of VEL

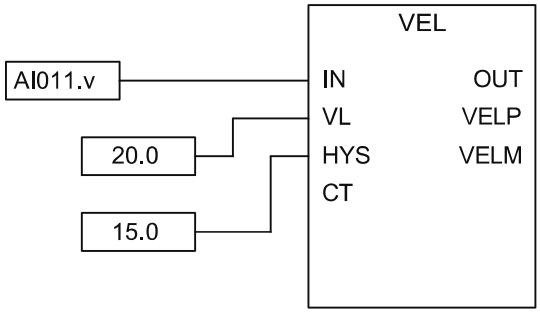

Figure A4.1-7 Example of VEL application logic

If the input value (IN) is engineering data, the output value (OUT) will also be engineering data.

VL and HYS are entered as engineering data.

Case of ANLG_S

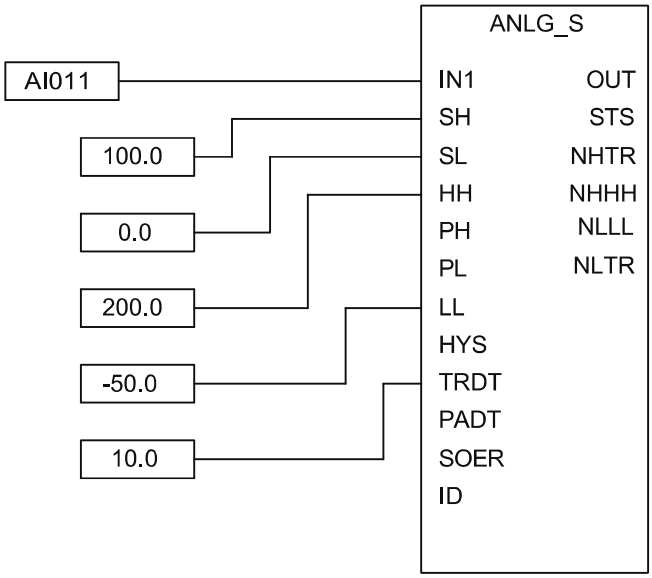

Figure A4.1-8 Example of ANLG_S application logic

In ANLG_S, make sure that you enter the following value if the input value (IN) is engineering data.

SH=100.0

SL=0.0

HYS is entered as engineering data.

TIP

When using ANLGI, apply the same process as ANLG_S.

A4.2 Shutdown due to channel failure

The following examples show how to create application logic for SCS shutdown in case of channel failure.

System Function Block for detecting channel failure

The following table shows the overview of function blocks for creating application logic for shutdown due to a channel failure.

Table A4.2-1 Function Blocks for shutdown due to channel failure

Example of failure to be detected	N-IO	FIO
At least one channel of all the AIO/DIO modules in SCS has failed.	SYS_IOALLST	
At least one channel of an AIO/DIO module in some node has failed.	SYS_N_NODEST	SYS_NODEST
At least one channel of an AIO/DIO module has failed.	SYS_N_IOST16	SYS_OUTST or SYS_OUTST16 for output modules. SYS_INST for input modules.
All channels of an AIO/DIO module have failed.		
The specified channel of an AIO/DIO module has failed.		SYS_CHST. SYS_OUTST or SYS_OUTST16 can also be used for output modules.

A failure in any channel of an FIO AIO/DIO module in a whole SCS or one node as well as a failure in a specific channel can be used as the condition for shutdown. You can combine these two conditions if necessary.

For maintenance of an I/O module, you can prevent shutdown logic from being activated by locking the appropriate module. For maintenance of an output module, the actuator connected with the output channels needs to be bypassed.

Shutdown after detection of any channel failures in a specified unit

The application logic can be created so that shutdown is executed if any output channel has failed in a certain unit (a whole SCS or specified node).

Shutdown due to any output channel failures in a node

You can use SYS_NODEST for FIO nodes, and SYS_N_NODEST for N-IO nodes to create application logic that executes shutdown in case of a failure of any output channel in a node. The following figure shows an example of application logic for FIO nodes.
First, add important outputs to one specific FIO node, as shown in the following figure. Next, create SYS_NODEST, specify a node number as an input parameter for the SYS_NODEST, and then connect the output parameter with the shutdown logic.

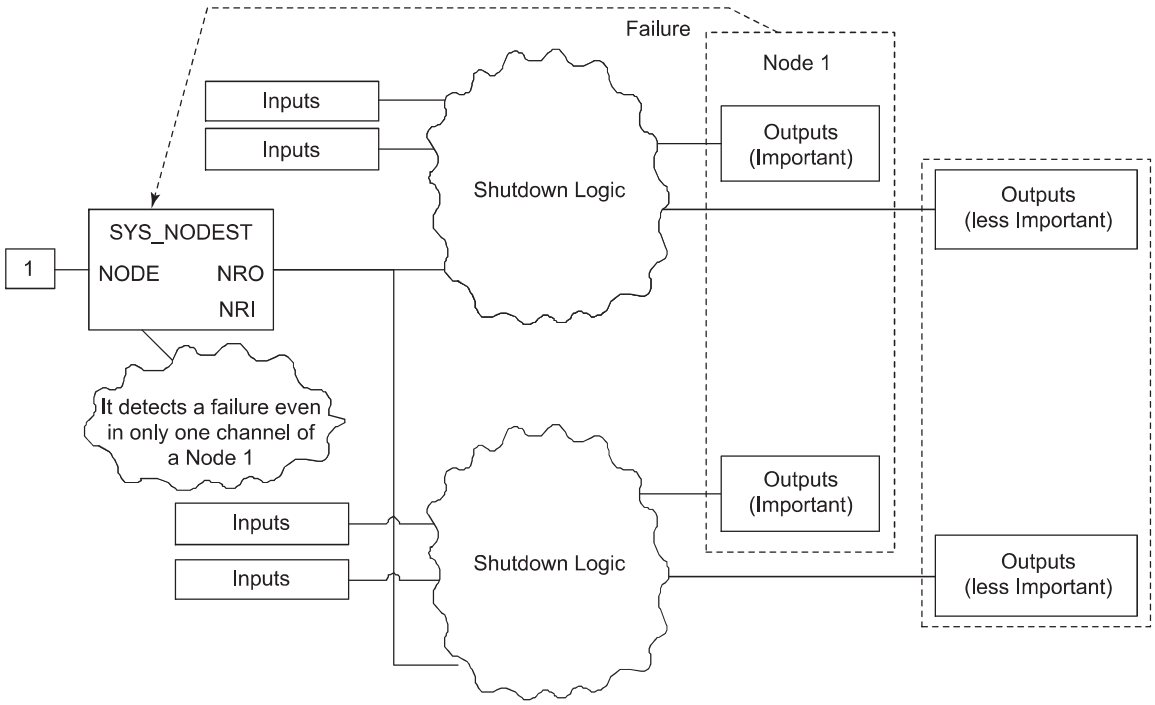

Figure A4.2-1 Shutdown due to any output channel failure in an FIO node

Shutdown due to any output channel failures of an SCS

The SYS_IOALLST is available to create application logic to execute shutdown in case of a failure in any output channel of an SCS.

The creation method of application logic is the same as the one for detecting a failure in a node. However, take appropriate care when using this logic, as the output channels that are not important are also checked for failure by this logic.

SEE ALSO

For more information about SYS_NODEST, refer to:

11.16, “SYS_NODEST (all I/O channels of FIO node status indicator)” in POU Reference Manual (IM 32P03B20-01EN)

For more information about SYS_IOALLST, refer to:

11.15, “SYS_IOALLST (all I/O channels of SCS status indicator)” in POU Reference Manual (IM 32P03B20-01EN)

Shutdown after detection of a failure in a specific channel

The application logic can be created to execute shutdown in case of a failure in specific I/O channels. This allows control of shutdown by responding to the failures of individual I/O channels.

Shutdown due to failures in several specific output channels

For FIO output modules, you can use SYS_OUTST, SYS_OUTST16, and SYS_CHST to create application logic that executes shutdown in case of a failure in specific output channels. For N-IO output modules, you can use SYS_N_IOST16.
In the case of an FIO output module, as in the following figure, create SYS_OUTST and specify the installation location (node number and slot number) of the output module as an input parameter in order to detect a failure in the output channels that acts as the shutdown trigger. The output parameter receives the failure status of each channel. Connect only the necessary channels with the shutdown logic.

For checking fewer channels in an FIO output module, the SYS_CHST can be used instead of the SYS_OUTST and SYS_OUTST16. To use the SYS_CHST, you need to specify installation locations of the channels (node number, slot number, and channel number).

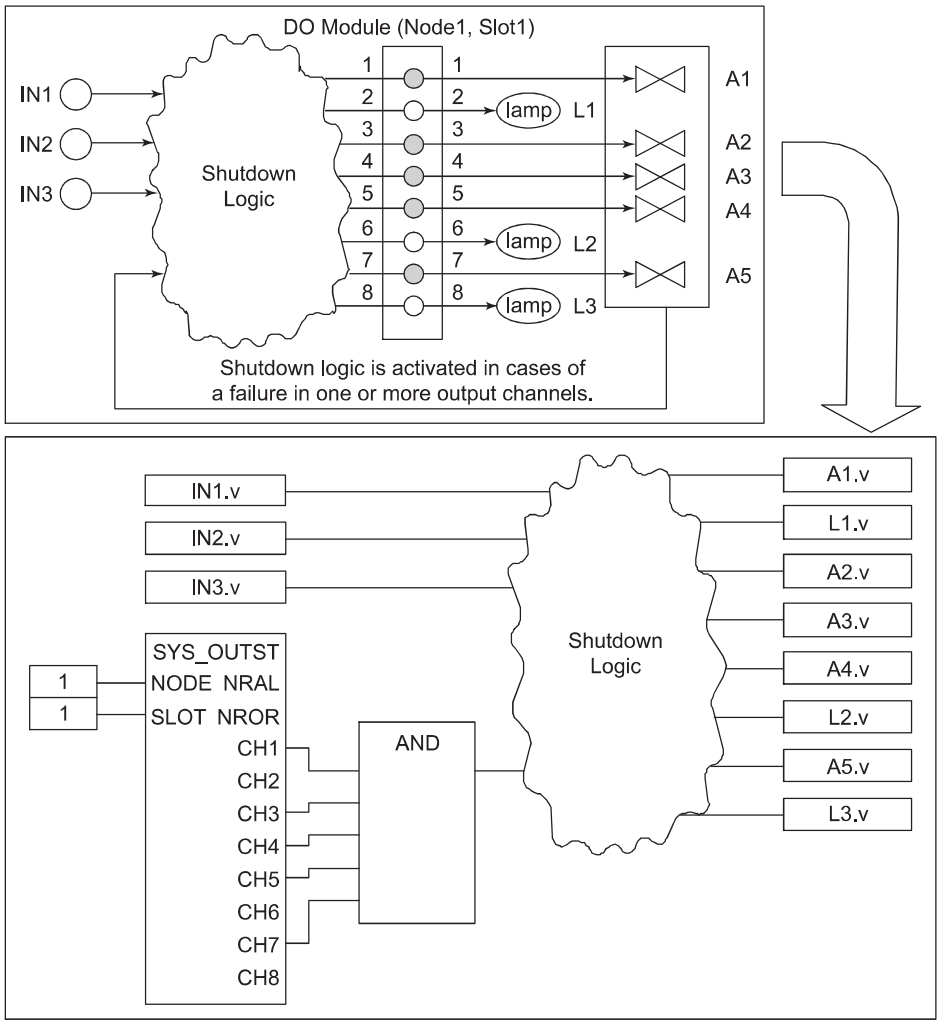

Figure A4.2-2 Example of shutdown logic to which a failure in each output channel is inputted in an FIO Output module

SEE ALSO For more information about SYS_OUTST, refer to:

- 11.18, “SYS_OUTST (FIO output module 8 channels indicator)” in POU Reference Manual (IM 32P03B20-01EN)
- 11.19, “SYS_OUTST16 (FIO output module 16 channels indicator)” in POU Reference Manual (IM 32P03B20-01EN)

Shutdown due to a failure in important input channels

To create application logic for shutdown in case of a failure in important input channels, specify the channel’s input value for a failure which invokes the shutdown demand. Additional application logic is not necessary.

When failure in an input channel is expected, after multiplexing inputs, use the Voter FB including BOOLVOTER, to create application logic.

Shutdown when all multiplexed input channels fail

You can use SYS_N_IOST16 for N-IO input modules, and SYS_INST or SYS_CHST for FIO input modules to create application logic that executes shutdown when all multiplexed input channels fail.

For this type of application logic, the channel's input value for a failure needs to be specified as a value that keeps the channel's NORMAL status in order to avoid shutdown due to only one input channel failure.

Shutdown when all multiplexed input channels fail

There are two methods of creating this type of application logic.

You can implement all multiplexed inputs on one input module with the other channels kept unused. This method detects the failures of all channels with simple logic by using SYS_INST for FIO input modules, and SYS_N_IOST16 for N-IO input modules.

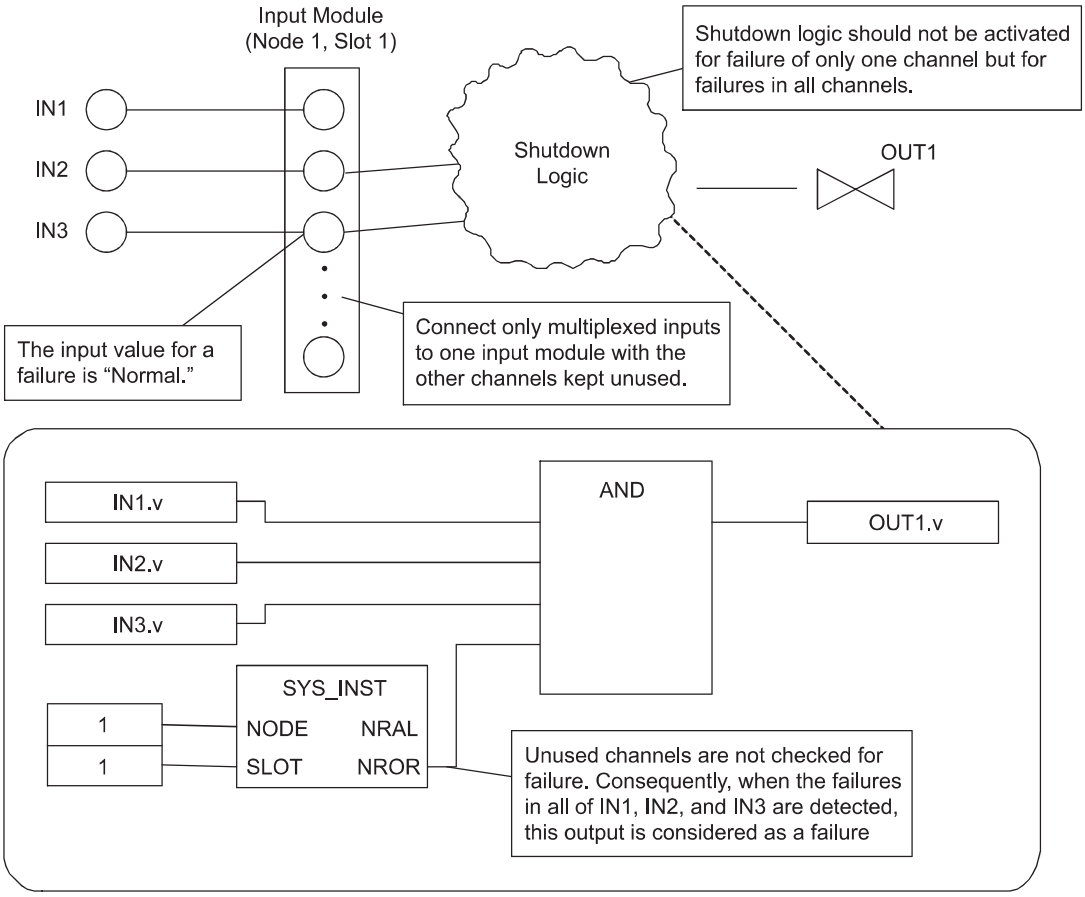

Figure A4.2-3 Example of application to execute shutdown when all multiplexed input channels fail in FIO Input modules (1)

In the other method, you can implement several multiplexed inputs on separate input modules. The advantages of this method are easier maintenance of modules and resistance to module failures; however, the logic of this method is quite complicated as compared to that of example 1. This case requires an AND operation after detecting the failure status of all multiplexed channels. For FIO input modules, use SYS_CHST to detect the failure status of each channel. For N-IO input modules, use SYS_N_IOST16 to detect the failure status of each channel.

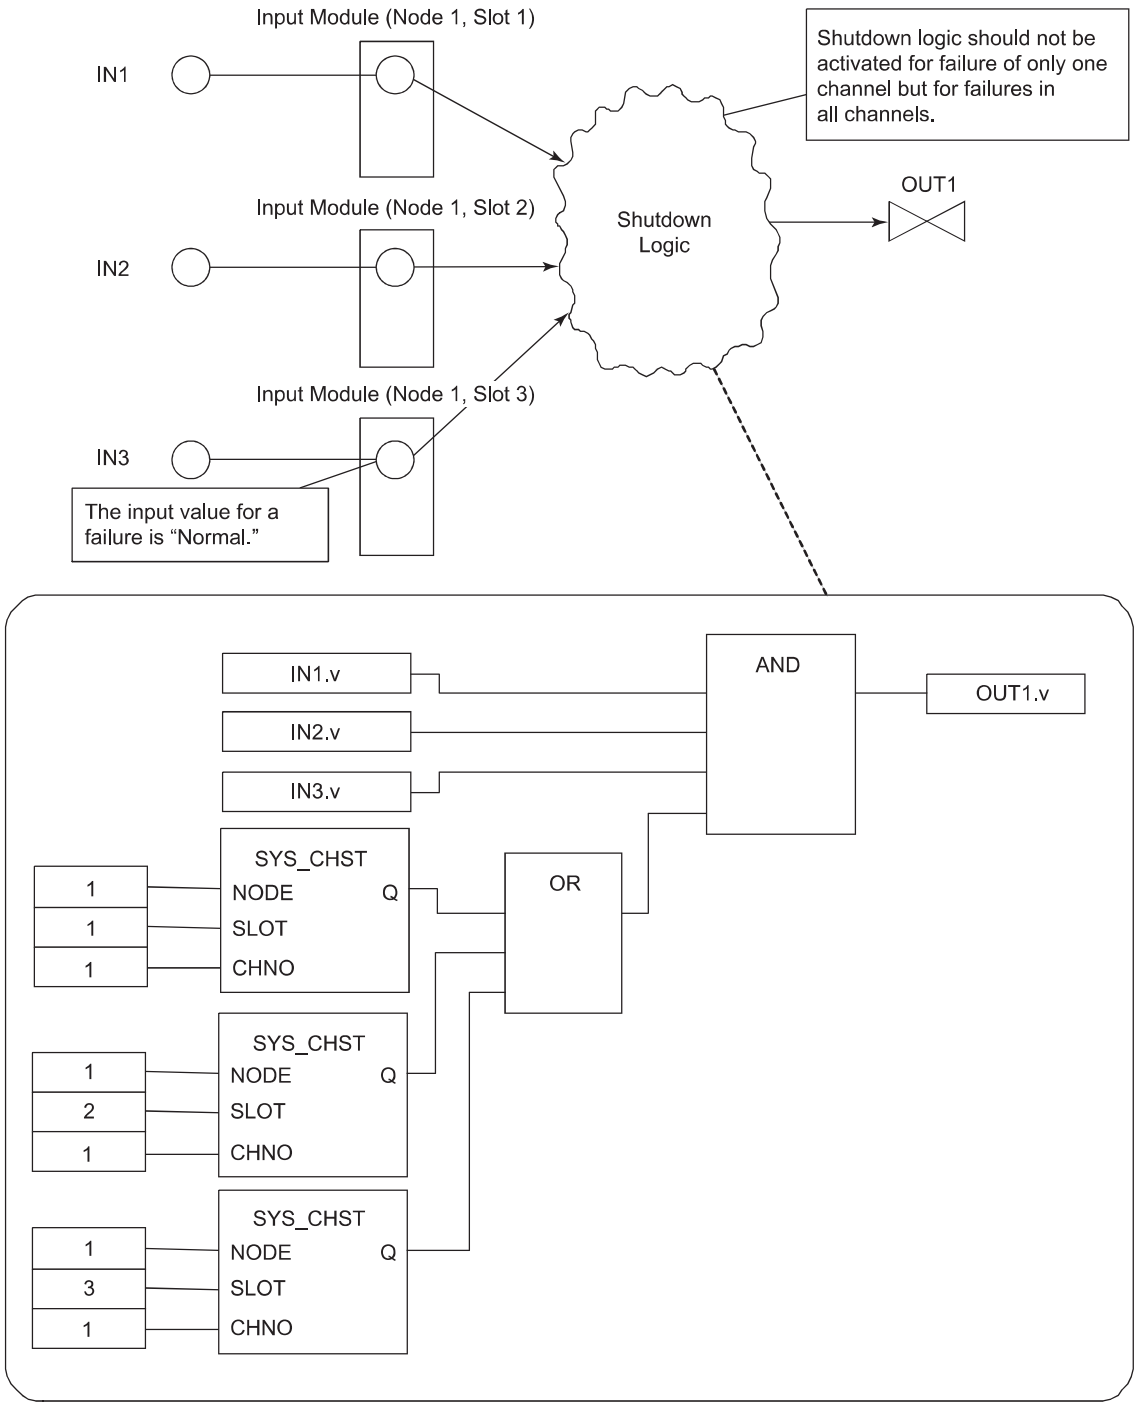

Figure A4.2-4 Example of application to execute shutdown when all multiplexed input channels fail in FIO Input modules (2)

SEE ALSO

For more information about SYS_INST, refer to:

11.20, “SYS_INST (FIO input module status indicator)” in POU Reference Manual (IM 32P03B20-01EN)

For more information about SYS_CHST, refer to:

11.21, “SYS_CHST (status indicator of FIO module channel)” in POU Reference Manual (IM 32P03B20-01EN)

A4.3 Example of displaying I/O status

This section provides an example of displaying I/O module status using function blocks.

TIP

This type of application is rarely needed to be created because I/O status is displayed on SENG.

Example of displaying I/O operating status

The SYS_DIAG is available if I/O operating status needs to be indicated on an external display. You can use SYS_IOMDSP for FIO I/O modules and SYS_N_IOMDSP for N-IO I/O modules.

To detect a failure in a whole SCS, the SYS_DIAG is available.

To display the status of individual modules, use SYS_N_IOMDSP for N-IO I/O modules and SYS_IOMDSP for FIO I/O modules. One function block is needed to display the status of one module.

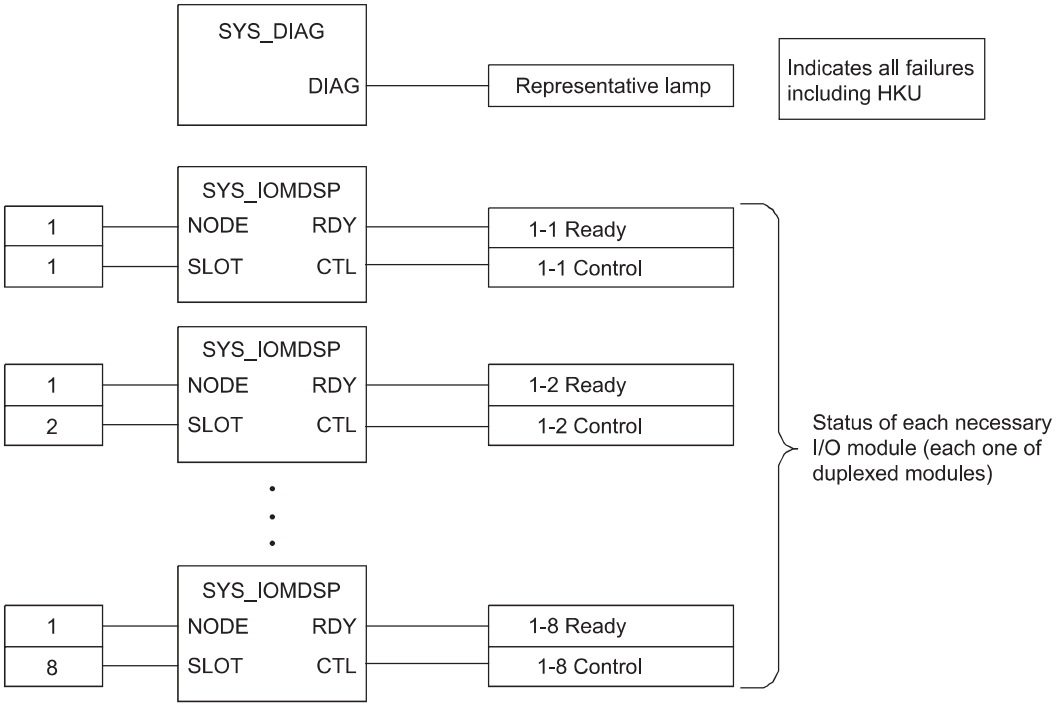

Figure A4.3-1 Example of displaying operating status of FIO I/O modules

SEE ALSO

For more information about SYS_DIAG, refer to:

11.7, “SYS_DIAG (diagnostic information output)” in POU Reference Manual (IM 32P03B20-01EN)

For more information about SYS_IOMDSP, refer to:

12.9, “SYS_IOMDSP (FIO module status indicator)” in POU Reference Manual (IM 32P03B20-01EN)

A4.4 Relations among AIO/DIO, Communication module and System FBs

This section describes the relationship between AIO/DIO modules that can be used in SCSs, communication modules and system function blocks. “Related” in this context refers to cases where an output value of an FB is changed if an error occurs in a module or data, or the data output to a module changes depending on the operation of the FB.

Table A4.4-1 Safety FBs

	FIO input module (*1)	FIO output module (*1)	N-IO I/O module (*1)	Subsystem communication module (Communication I/O data) (*1)	Safety subsystem communication module(*1)	Modbus slave communication module (*1)
SYS_STAT	No	Yes	Yes (*2)	No	No	No
SYS_FORCE	Yes	Yes	Yes	No	No	No
SYS_FORCE_SF	No	No	No	No	Yes	No
SYS_DIAG (*3)	Yes	Yes	Yes	Yes	Yes	Yes
SYS_IOALLST (*4)	Yes	Yes	Yes	No	No	No
SYS_NODEST (*4) (*5)	Yes	Yes	No	No	No	No
SYS_N_NODEST (*4) (*6)	No	No	Yes	No	No	No
SYS_OUTST (*5)	No	Yes	No	No	No	No
SYS_OUTST16 (*5)	No	Yes	No	No	No	No
SYS_INST (*4) (*5)	Yes	No	No	No	No	No
SYS_N_IOST16 (*4) (*6)	No	No	Yes	No	No	No
SYS_CHST (*4) (*5)	Yes	Yes	No	No	No	No
SYS_ALLSD	No	Yes	Yes (*2)	No	No	No
SYS_IOSD (*5)	No	Yes	No	No	No	No
SYS_N_IOSD (*6)	No	No	Yes (*2)	No	No	No

*1: Yes: Related
No: Not related
*2: Only output channels
*3: If a failure or data error occurs, the output parameter IOER is set to TRUE.
*4: When errors occurred in the communication route between CPU and I/O modules (except for the error occurred in one of the redundant ESB buses with that routed properly), the output becomes FALSE.
*5: For FIO
*6: For N-IO

Table A4.4-2 Interference-free FBs

SYS_STAT_SC	No	No	No	Yes	No	No
SYS_FORCE_SC	No	No	No	Yes	No	No

*1: Yes: Related
No: Not related
*2: When errors occurred in the communication route between CPU and I/O modules (except for the error occurred in one of the redundant ESB buses with that routed properly), the output of the I/O modules will hold the previous output values.
*3: For FIO
*4: For N-IO

A4.5 Example of using BOOL-type Data Manual Operation FB (MOB_*)

By using the Bool-type Data Manual Operation Function Block with Answerback (MOB_11/ MOB_21), you can operate the valve(s) using switch-type face plate from HIS.

In addition to making the switch operation available from HIS, this type of function blocks is capable of outputting a shutdown instruction immediately regardless of the manipulated output value from the HIS if a shutdown event occurs. They also have the function to check the answerback input against the manipulated command value, security password function, manual operation enabling function and so on. The manual operation of MOB_11 or MOB_21 from HIS can be used for operating valves at the startup of a plant or for testing the behavior of devices when you perform maintenance work. Note that when you manually operate MOB_11 or MOB_21, entry of password is required.

You can request an output of pulse status from an Auto-Reset Bool-type Data Manual Operation FB (MOB_RS) by using CENTUM HIS. This FB is used to reset from the shutdown status or to reset alarms.

SEE ALSO For more information about functions of the bool-type manual operation function blocks, refer to:

7., “Function blocks for integration with CENTUM (Safety FBs)” in POU Reference Manual (IM 32P03B20-01EN)

Example of using BOOL-type Data Manual Operation FB (MOB_21)

This is an example where the MOB_21 FB is used under the following conditions:

- During the start-up of the plant.
- Shutdown of the SCS occurred and the cause of the shutdown has been cleared.
- The valve is opened one by one using manual operation from HIS.

This example is applicable if a shutdown event is the only criterion to disable manual operation, and if manual operation is enabled whenever the shutdown event is solved.

For DTS, SHDN is connected to signals from the shutdown logic, SS to FALSE.

To enable the manual operation immediately after the shutdown event is solved, connect TRUE to SW. If the SW is always TRUE, the value of IN never be referenced, so set any value to IN.

Since the shutdown signal has higher priority, when the input value of SHDN becomes FALSE, the manual operation becomes disabled even if the SW is always TRUE.

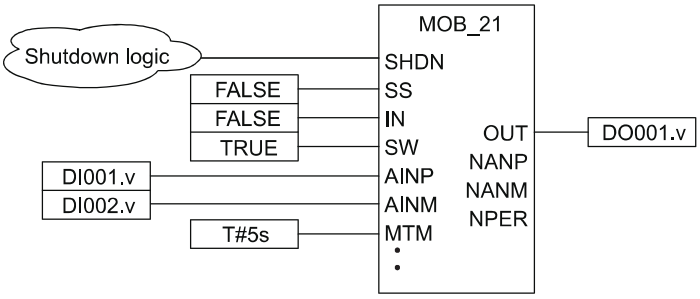

Figure A4.5-1 Example of using BOOL-type Data Manual Operation FB (MOB_21)

The above figure is an example of DTS. For ETS, set the SS input to TRUE.

Example of valve with only Full Close Limit Switch

For manipulating the valve with only Full Close Limit Switch, use the Bool-type Data Manual Operation with Two-Position Answerback (MOB_11) and enter an inverted Full Close Limit Switch signal into AIN.

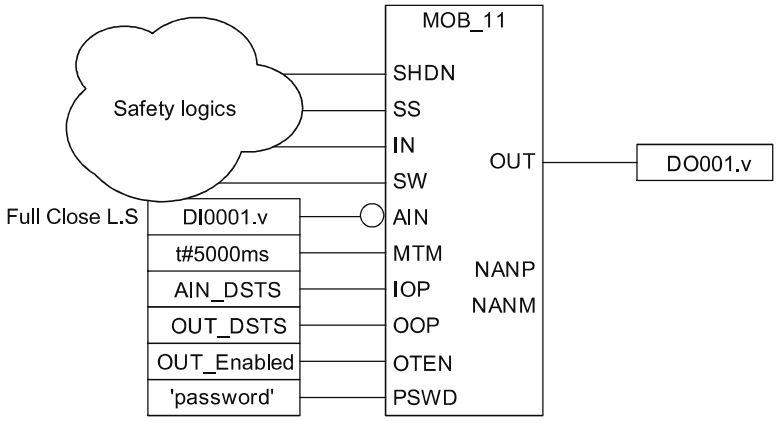

Figure A4.5-2 For valve with only Full Close Limit Switch

Example of manipulating Two-position analog valve

Connect analog signal to SCS.To allow an HIS to manipulate an analog valve having only two statuses, Full Open and Full Close, configure the loop as shown in the following figure.

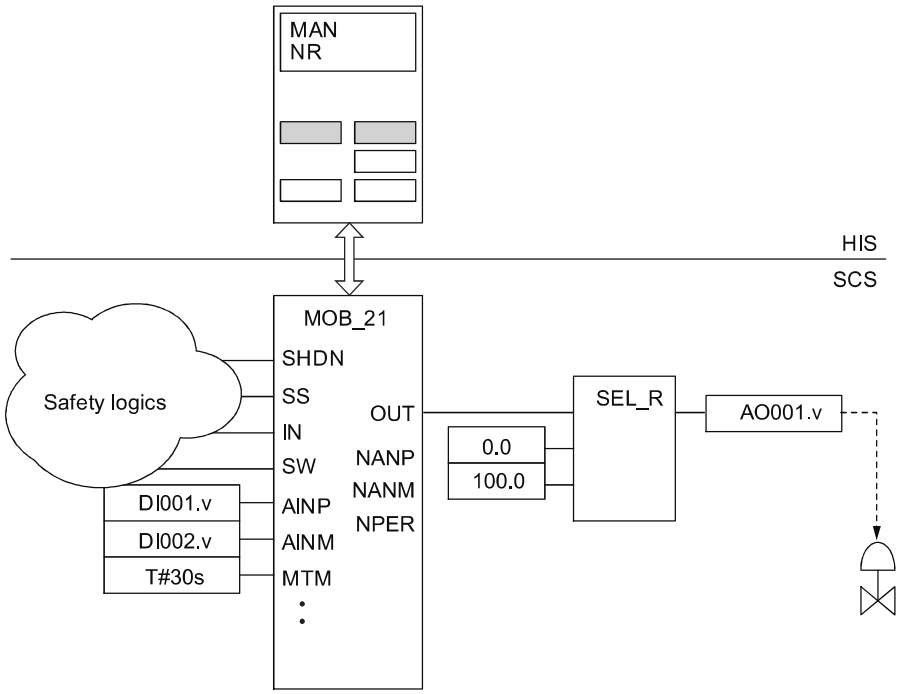

Figure A4.5-3 For manipulating Two-position analog valve

Example of No Answerback check

If Answerback check is not required, looping back the output value to Answerback input disables the Answerback check function. In this case, PV can be used for checking (visually) operations from CENTUM.

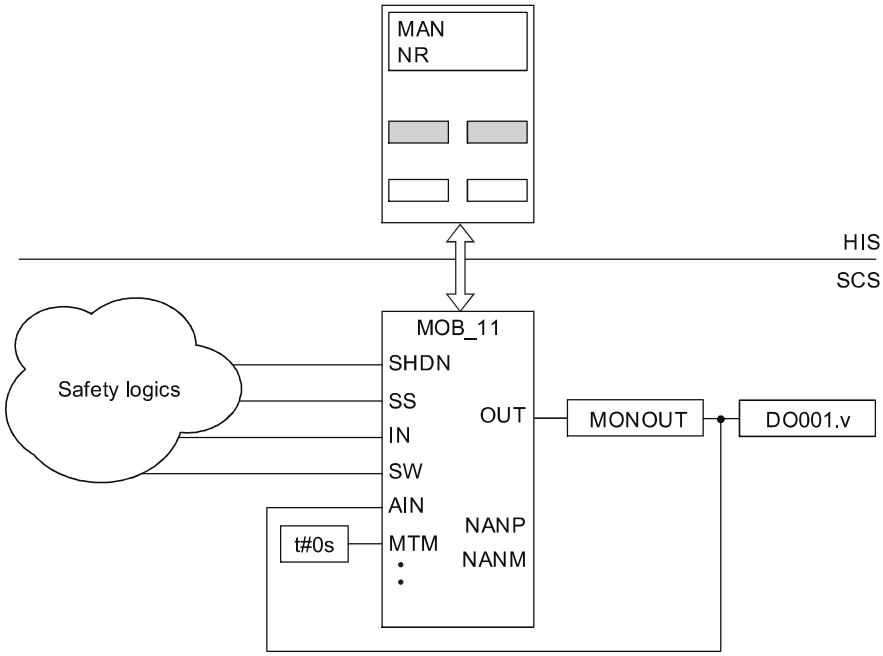

Figure A4.5-4 Case where No Answerback check is required

A4.6 Construction example of First-up Alarm function

In ESD applications and similar, even if the system is shut down due to a certain cause, it might lead to other shutdown causes immediately or multiple shutdown-causing factors may mutually interact in the application logic. As a result, it is not always possible to identify the first cause.

The first-up function allows you to identify the event (factor) that was generated first among grouped events.

Overview of First-up Alarm function and application examples

The first-up alarm function is constructed by combining First-up Alarm Annunciator (ANN_FUP) and First-up Alarm Annunciator Reset (FUR_RST). A First-up Alarm Annunciator (ANN_FUP) allows identifying and outputting events that occurred first and second among grouped events. If a CENTUM HIS is connected, an annunciator message is output for the event that occurred first. A First-up Alarm Annunciator Reset (FUP_RST) is used to reset the first-up alarm status of ANN_FUP.

An example of constructing the first-up alarm function using these FBs is shown below.

Example of First-up Alarm and outputting failure of rest operation to HIS

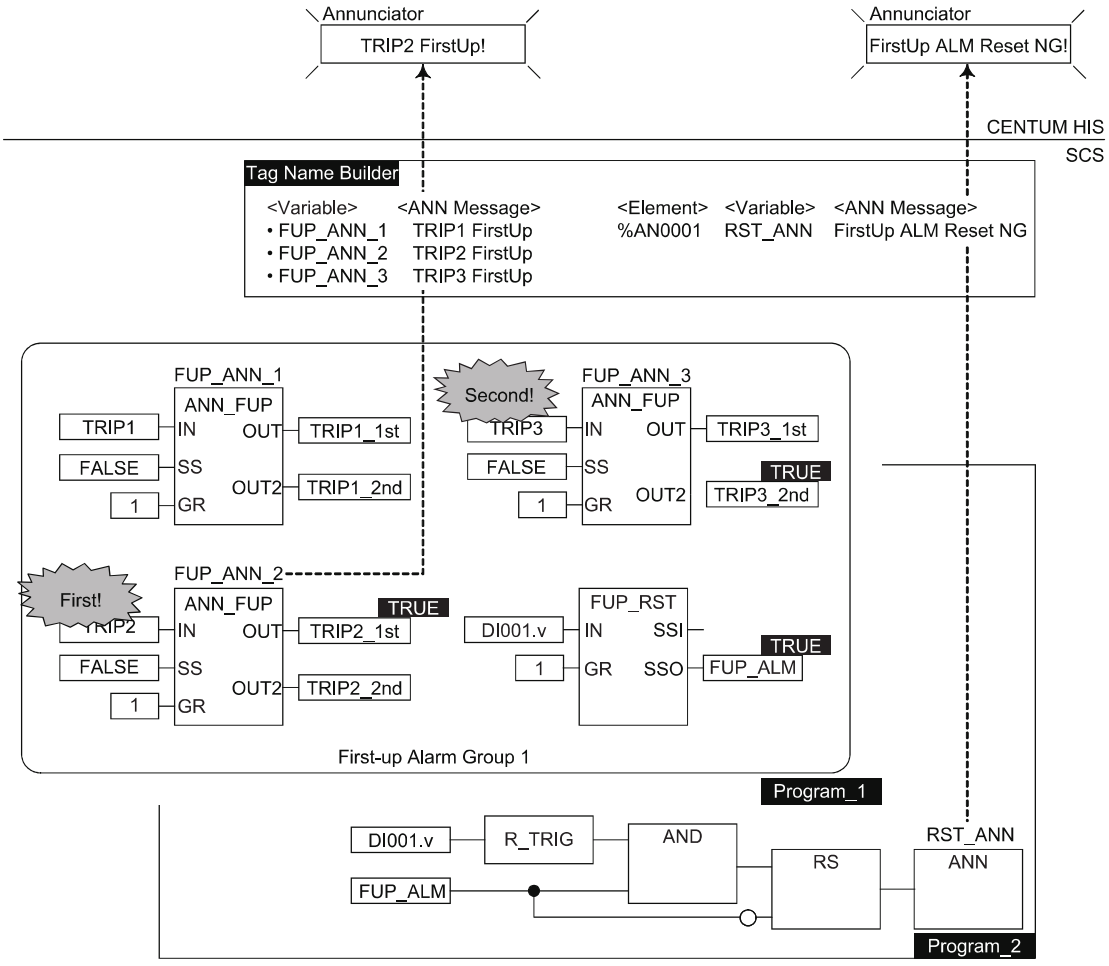

Figure A4.6-1 Application of detecting First-up Alarm

Program_1 inputs events TRIP1, TRIP2, and TRIP3 to their respective ANN_FUPs and set them as First-up alarm group 1. Each ANN_FUP is assigned an instance name. A DI signal

DI001, which is operated by a hardware console, etc. and input to SCS for alarm reset, is input to FUP_RST.

Program_2 creates logic to check if the first-up alarm status is cancelled when alarm reset operation is performed.

Annunciator messages corresponding to each instance are defined in the Tag Name Builder or iDefine.

In the example above, events are generated in the order of TRIP2, TRIP3, and then TRIP1. In this case, OUT (TRIP2_1st) of the instance name FUP_ANN_2 and OUT2 (TRIP3_2nd) of FUP_ANN_3 become TRUE and the annunciator message for the first-up alarm (annunciator message of FUP_ANN_2) is output to HIS. When the first-up alarm is generated, SSO (FUP_ALM) of FUP_RST becomes TRUE. In the status where FUP_ALM is TRUE, the first-up alarm status is not cancelled even if the alarm reset signal (DI001) is received. In such cases, an annunciator message notifying that the alarm reset operation failed is output. Since ANN_FUP does not have SOE functions, connect SOE FB as required.

A4.7 Considerations on using Time Synchronization Function Block (SYS_SETTIME)

Observe the following usage limitations and considerations when you set the system time of SCS and the Vnet/IP or V net time by using the function block (SYS_SETTIME).

The following figure shows an example to set 2:00:00 on input of a trigger signal by using the SYS_SETTIME function block.

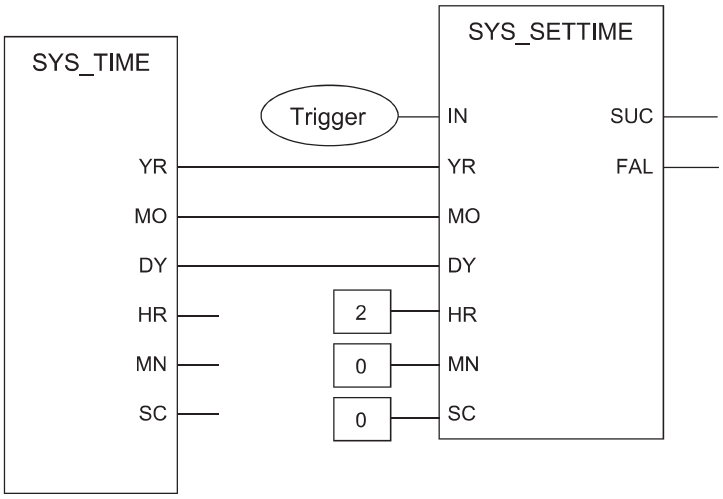

Figure A4.7-1 Usage example of SYS_SETTIME

Considerations on setting the time in the usage example are as follows:

- At the moment the time setting is executed, the date must match between the trigger signal providing side and the SCS to which the time is set. To ensure matching dates, offset more than one minute from 0:00 AM. If the time is set around 0:00 A.M.If the function block is used to set a time around 0:00 A.M. If the date of the trigger signal providing side and the date of the SCS may become different. Therefore, a wrong date may be set to the SCS.
- Before using the time synchronization function block, set the time using the time setting function of SENG or HIS.

SEE ALSO For more information about time synchronization function block (SYS_SETTIME), refer to:

12.3, “SYS_SETTIME (SCS time setting)” in POU Reference Manual (IM 32P03B20-01EN)

Usage limitations of Time Synchronization Function Block

Do not use the time synchronization function block under the following states: An alarm may occur, due to resetting of the time or time diagnostic error in inter-SCS safety communication.

- Using IRIG-B time synchronization in the time synchronization method
- Using the time synchronization function block in two or more SCSs.
- Using two or more time synchronization function blocks in one SCS.
- A station with Vnet/IP firmware earlier than Rev. 8 is connected to Vnet/IP.
  The time synchronization function block can be used when the Vnet/IP firmware of the station is updated to Rev. 9 or later.
- SCS with SCS system program R2.03.58 or earlier is connected to the same control bus.

The time synchronization function block can be used when all SCS system program release numbers of all SCSs are updated to R2.03.59 or later.

In addition, if the SNTP server is connected to Vnet/IP, the time setting by the time synchronization function block is disabled.

Time span for the Time Synchronization Function Block for detecting DI input and setting the SCS time

Use the DI input that is connected to the SCS using this function block as the input signal for IN.

The maximum time (Tsettime), which is from detection of DI input to change of the SCS time, is obtained from the following formula:

Tsettime = Tscan x 2 + Processing time of Input module + 50 ms - Idle time

Idle time = Tscan - Application logic execution time

SEE ALSO For more information about check application logic execution time, refer to:

“● CPU processing time” in “■ Confirmation of CPU processing time and consideration of idle time” in A7.1, “Definition of SCS scan period” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about application logic execution time, refer to:

12.1, “SYS_SCAN (execution time indicator)” in POU Reference Manual (IM 32P03B20-01EN)

A5. Library projects

It is possible to improve engineering efficiency by creating functions and function blocks commonly used in multiple SCSs as library projects and use them from SCS projects. This section explains how to create library projects and precautions on how they differ from SCS projects.

When performing engineering using iDefine, you cannot use function blocks in library projects, which are created using SCS Manager, from iDefine or add function blocks to the library projects from iDefine.

Overview of library projects

IMPORTANT

Create an individual copy of the necessary library projects for each SCS project that uses them. Avoid using one library project from multiple SCS projects in order to prevent modification of one library project from affecting multiple SCS projects.

Library projects are a part of an SCS project. It is possible to use multiple library projects from one SCS project. When using multiple library projects, be careful so that names of functions and function blocks do not overlap.

Note that it is not possible for a library project to reference another library project.

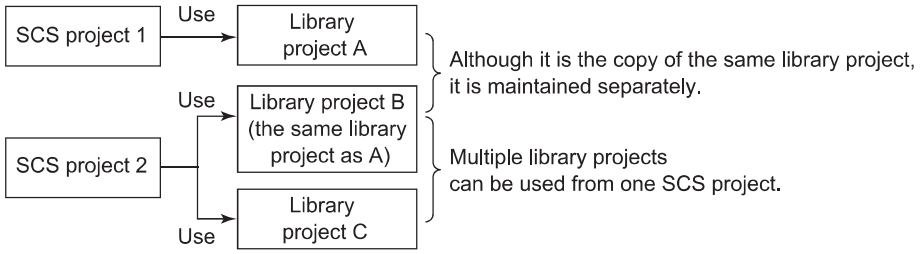

Figure A5-1 Overview of library projects

A5.1 Creation of library projects

Create an original library project and debug it; it can be copied and used for several SCS projects.

Creation procedure of library projects

1. On SCS Manager, choose [New Project/Library] from the [File] menu, and then choose [SCS Library] from "Template" so as to create a new library project.
   It is recommended to create a folder called "USERLIB" immediately below the `C:\RS-Projects` folder created at installation and place library projects there.

TIP

When using AD Suite, the name of the folder where you place the original library projects should consists of up to eight single-byte characters.

2. Use SCS Manager and Multi-Language Editor to define commonly used functions and function blocks.
3. Use SCS Manager and Multi-Language Editor to create a program to test the functions and function blocks defined in step 2.
4. Check that there are no programming errors in the build.
5. Execute a simulation test and confirm that functions and function blocks work as intended.
   Note that an actual SCS is not required at debugging. Library projects cannot be debugged using SCSs.
6. Analyze the project using Integrity Analyzer to confirm that there are no problems.

SEE ALSO

For more information about library project settings, refer to:

"Libraries" in "Workbench" in the Workbench User's Guide

Procedure to copy library projects for each SCS project

1. Use SCS Manager and create an SCS project.
2. Use Windows Explorer to copy the original library project immediately below the `LIBRARIES` folder located in the SCS project folder.
3. Select [Add/Remove Dependencies] from the [Tools] menu of SCS Manager.
   The copied library is associated with the SCS project. This allows using one library only from one SCS project.
4. User-defined functions and user-defined function blocks created as part of the library can be used when creating POUs with the FBD, LD and ST languages. If the user-defined function block is used in an ST, an Integrity Analyzer warning message will be displayed to prompt for authorization.

With the procedure above, the library project will become available to access from the SCS project. If the library project is to be used in other SCS projects as well, repeat copying the library project for each SCS project.

IMPORTANT

Library projects are divided into the original library projects created in the `C:\RS-Projects\USERLIB` folder and those copied to the `LIBRARIES` folder for each SCS project. Make sure to keep the library projects updated so that the libraries in both folders maintain the same contents.

TIP

If you refer to an SCS project from a remote PC, specify the library project path of the Dependencies in the UNC format.

Figure A5.1-1 Specification example of UNC-format library project path

SEE ALSO

For more information about defining the dependency of a library project, refer to:

"Using Libraries in a Project" in "Libraries" in "Workbench" in the Workbench User's Guide

Folder structure of library projects

The figure below shows the folder structure for library projects.

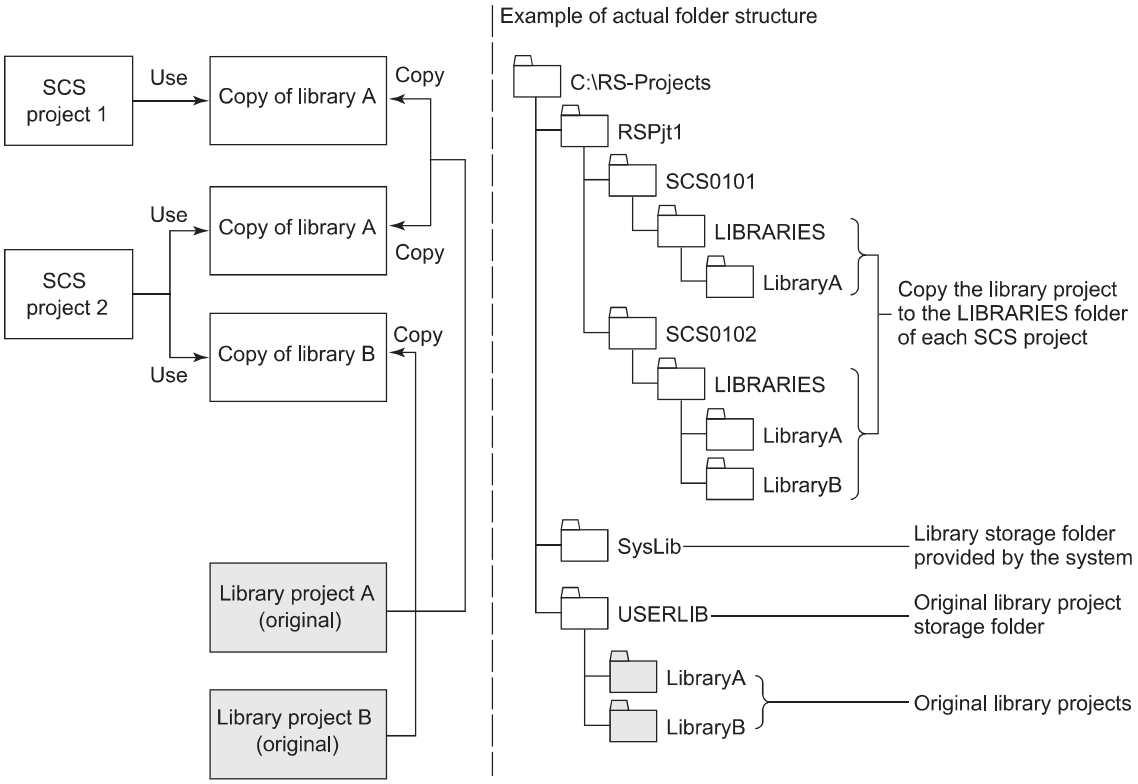

Figure A5.1-2 Folder structure of library projects

A5.2 Items set for library projects

When creating user-defined functions and function blocks for library projects, it is mandatory to set certain items for projects, configuration, resources, functions and function blocks, while some items can be set arbitrarily.

Items set for library projects

The table below summarizes items that must be set to create user-defined functions and user-defined function blocks for a library project.

Table A5.2-1 Items set for library projects

Classification	Item	Setting	Remarks
Project	Project name	Mandatory	
	Project comment	Arbitrary	
	Password setting	Arbitrary	
	Project description	Arbitrary	
Configuration	Configuration name	Mandatory	
	Configuration comment	Arbitrary	
	Target	Mandatory	
	Password setting	Arbitrary	
	Configuration description	Arbitrary	
	Network	No need to specify	
	Connection IP address	No need to specify	

Continues on the next page

Table A5.2-1 Items set for library projects (Table continued)

Classification	Item	Setting	Remarks
Resource	Resource name	Mandatory	
	Resource comment	Arbitrary	
	Resource number	Mandatory	Enter any value in the range from 1 to 4094
	Target	Mandatory	
	Generate debug information	Arbitrary	
	Code for simulation	Mandatory	
	Code generation setting	Mandatory	Specify TIC code
	Embed Symbol Table	No need to specify	
	Embed Zip Source	No need to specify	
	Trigger cycles	Arbitrary	
	Cycle Timing	Arbitrary	
	Detect errors	No need to specify	
	Nb of stored errors	No need to specify	
	Cycle to cycle/Real time	Arbitrary	
	Memory for Retain	No need to specify	
	Password	Arbitrary	
	Resource description	Arbitrary	
User-defined function/ user-defined function block	POU name	Mandatory	
	POU comment	Arbitrary	
	Debug information	Arbitrary	
	Password	Arbitrary	
	POU description	Arbitrary	

A5.3 Precautions on library projects

Pay attention to the following points when creating and using library projects.

- How to use library projects
- Software revision of SCS project and library project
- Operations when incorporating library projects into SCS project
- Differences between SCS projects and library projects
- Operations on SCS projects and relationship with libraries
- Precautions when testing library projects
- Precautions when using Integrity Analyzer
- How to make changes to library projects

How to use library projects

- With a library project, it is possible to create logic for user-defined functions and user-defined function blocks and debug them in a simulation test. Note, that unlike in the case of SCS projects, it is not possible to download them to an SCS or perform debugging using an SCS.
- In order to debug user-defined functions and user-defined function blocks, a special program for testing them is required. Create a program for testing purposes if you inspect user-defined functions and user-defined function blocks by Integrity Analyzer.

A5.3.1 Software revision of SCS project and library project

Match the revision numbers of software for creating SCS Project and for creating Library Project.

However, even if the revision number of software for creating Library POU is later than the revision number of software for creating the SCS Project, you don't have to match the revision numbers unless the Library POU includes FB/FU that is unsupported by the SCS Project.

A5.3.2 Operations when incorporating library projects into SCS project

User-defined functions and user-defined function blocks created in a library project have restriction as follows in an SCS project.

- They cannot be opened with Multi-Language Editor.
  They must be referenced using the library project.
- The logic cannot be printed out.
  Print the logic via the library project.

A5.3.3 Differences between SCS projects and library projects

The table below summarizes functions that can only be used in library projects and cause errors when creating SCS projects.

Table A5.3.3-1 Functions that can only be used in library projects

Function	Library project specification	SCS project specification
Library project name, configuration name, resource name	Up to 64 characters including alphabets, numbers and underscore. The first letter must be an alphabet character.	Fixed to SCSddss
Resource number	In the range from 1 to 4094	Fixed to ddss

Note that, in library projects, variable names should be kept within 18 characters and POU names (user-defined functions and user-defined function blocks) used in a library project should be kept within 16 characters, although longer names will not cause errors at building.

A5.3.4 Operations on SCS projects and relationship with libraries

Once pasted from the original library projects into SCS projects, the libraries constitute a part of the SCS projects. Therefore, operations on the SCS projects are also applied to the pasted libraries as well.

- The data of libraries is also saved in the master database. The same rule applies to restoration as well.
- The data of libraries is saved in the version control of an SCS project. The same rule applies to restoration as well.

A5.3.5 Precautions when testing library projects

In order to test functions and function blocks defined in a library project, it is necessary to open the original library project in SCS Manager and perform a logic simulation test. In order to perform this test, create a program for testing purposes in the original library project. In the SCS project that uses the libraries, it is possible to check the inputs and outputs of user-defined functions and user-defined function blocks from the library project, but the internal operations cannot be checked.

Note that if it is not necessary to debug functions and function blocks defined in the library project, the abovementioned test program is not required.

A5.3.6 Precautions when using Integrity Analyzer

Test program

When using Integrity Analyzer to analyze user-defined functions and user-defined function blocks, the original library project requires a test program that calls its functions and function blocks. This is because Integrity Analyzer analyzes functions and function blocks via the program and display warnings and errors that occur during the test. This test program is used purely for analysis by Integrity Analyzer and has nothing to do with the operation of an SCS project that uses the library.

"Authorize" operation

It is possible to perform "authorize" on a library project as well. However, performing "authorize" on a library project does not mean that the SCS project that uses the library is authorized.

The "authorize" of the SCS project does not become valid until the library project is incorporated in the SCS project and built using the SCS project.

Starting operation of Integrity Analyzer

Integrity Analyzer is started in the same way as for an SCS project. Choose [Engineering] from [Tools] menu of SCS Manager. The Engineering launcher menu appears; select [Integrity Analyzer] to launch Integrity Analyzer.

A5.3.7 How to make changes to library projects

To make changes to library projects, follow the procedure below.

1. Make the desired changes to an original library project and debug them.
2. Copy the original library project and paste it to the corresponding library folder of an SCS project.

It is not always necessary to make changes to an original library project, but the changes must be reflected in all the libraries including the original library project eventually.

A6. SCS link transmission

There are the following types of SCS link transmission.

- SCS link transmission safety communication (Safety function)
  This establishes a safety communication between SCSs in the same domain. A safety loop can be established between the sending side and receiving side SCSs.
- SCS global switch communication (Interference-free function)
  This establishes interference-free communication between SCS and CENTUM stations (FCS, APCS, and GSGW; hereafter collectively referred to as FCS) in the same domain.

SEE ALSO

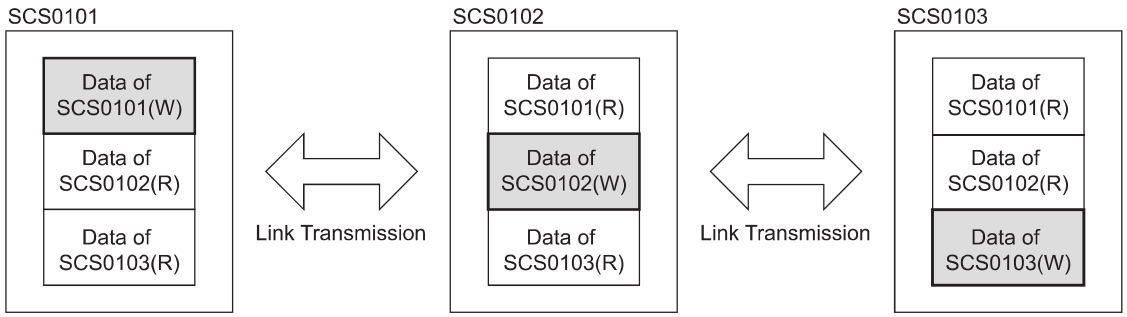
For more information about basic functions of SCS link transmission, refer to:

A6.1, “Overview of the SCS link transmission” on page A6-2

For more information about engineering for SCS link transmission, refer to:

A6.3, “SCS link transmission definition” on page A6-11

For more information about SCS global switch communication, refer to:



A6.5, “SCS global switch communication” on page A6-24

A6.1 Overview of the SCS link transmission

This section describes the overview of the SCS link transmission.

■ SCS link transmission

You can use the link transmission function of control bus to broadcast data of a station periodically to all other stations in the same domain (simultaneous notification). Vice versa, a station can also receive the broadcasts of other stations and you can use the received data in the application logics.

W: An SCS can write its own data.
R: Data of other SCS are read only.

Figure A6.1-1 SCS link transmission

● Communication specification

The main communication specifications of SCS link transmissions are as follows:

- Communication range: within a domain. However, V net router style S3 or above enables to make SCS Link Transmission Global Switch Communications between V net domain and Vnet/IP domain connected with V net router. Please consult the explanation in the reference link.
- Control bus: V net, Vnet/IP (either of them)
- Max. number of stations: 64 (Max. number of stations to communicate with stations: 63)
- Transmission period: Every 100 ms (fixed)
- Type of data exchanged among SCSs through SCS link transmission: BOOL type data only (Analog-type and integer-type is not supported)

SEE ALSO For more information about virtual domain link transmission when using a V net router of style S3 or above, refer to:

"■ Virtual domain link transmission" in Appendix 4.4, "System expansion with V net router connection" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

● Read and write transmission data

In SCS link transmission, bits in the received data are assigned to the dedicated FBs as input and read by the application logic. Bits in the data to be sent are assigned to the dedicated FBs as output and sent to other stations.

- Up to 1000 FBs can be used as input FBs of SCS link transmission per SCS (This is irrelevant to the sending station types such as SCS or FCS). The number of FBs for receive data per station is not limited.
- Up to 128 bits can be assigned to the output FB of SCS link transmission per SCS.

SCS link transmission types

SCS link transmission is mainly for the safety data communications among SCSs, and the interference-free communications between SCS and FCS (including APCS and GSGW). There are two types of communications:

- Data communications among SCSs: SCS link transmission safety communication
- Data communications between SCS-FCS: SCS global switch communication

SCS link transmission safety communication

SCS link transmission safety communication is a feature for communicating safety data among SCSs.

Safety communication

SCS link transmission safety communication attaches safety information to the communication data values, therefore, the receiving SCS can validate the received data values according to the safety information (safety-layer). Due to this validation, SCS link transmission safety communication data can be used in the following safety loops that across SCSs: The supported SIL varies depending on the SCS used.

- Between SIL3 SCS and SIL3 SCS, it can be used in safety loops up to SIL3
- Between SIL2 SCS and SIL2 SCS, it can be used in safety loops up to SIL2
- Between SIL3 SCS and SIL2 SCS, it can be used in safety loops up to SIL2

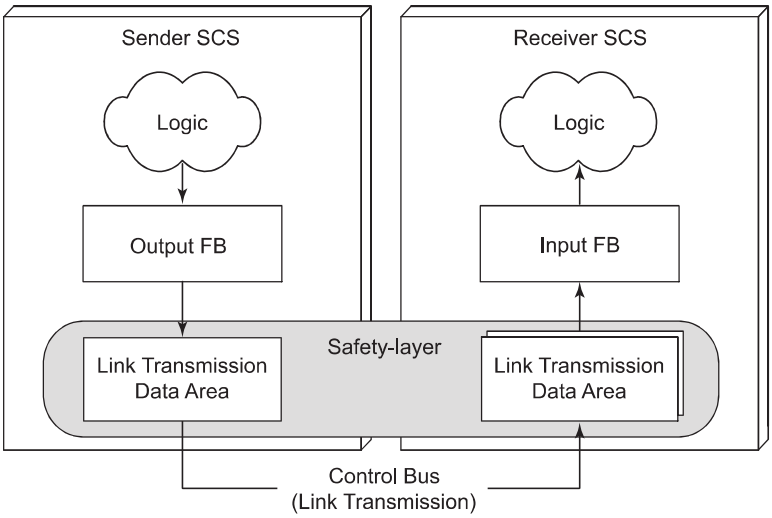


Figure A6.1-2 SCS link transmission safety communication overview

SCS actions on abnormality

When an error is detected by safety-layer, SCS will act as follows:

- Initiate a system alarm on the diagnosis error (alarm class 1).
- Set the statuses of the data received from the corresponding station to BAD.
- Use the fail-safe data values specified on the builder to replace the data values of input FBs.

When the diagnosis error is recovered, SCS will act as follows: Since the error status is not latched, it may be necessary to make the application to latch the error status.

- Initiate a system alarm on the recovery.
- Set the statuses of the data received from the corresponding station to GOOD.

- Input FBs use the data values that are refreshed after recovery.

SCS link transmission global switch communication

Global switch communication

Through link transmission, SCS can read data of FCS global switches. Vice versa, FCS can receive data from SCS as global switches.

Note the following when using global switch data:

- SCS can read 256 bit data of FCS global switches.
- SCS link transmission global switch communication is interference-free communication. For the applications to use the received FCS data, the dedicated FB should be used. The input data from the dedicated FB cannot be used in the safety application logics.
- The global switches in FCS that can accept the SCS link transmission data are the global switches from %GS001 to %GS128. The switches from %GS129 are not available for SCS link transmission data.

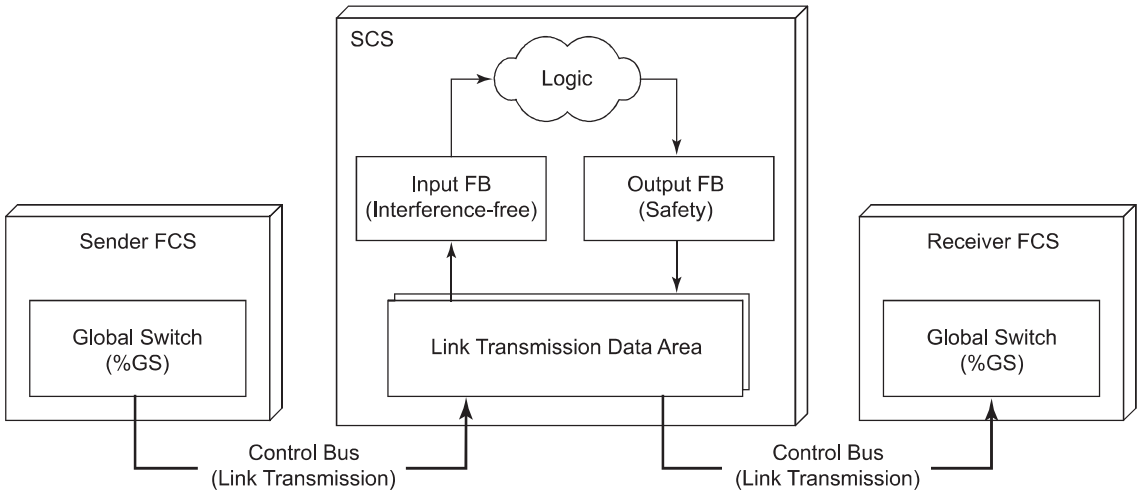

Figure A6.1-3 Data exchange between SCS and FCS through link transmission

SCS actions on communication error

When a communication error occurs or when the sender FCS stops, SCS will act as follows:

- Initiate a system alarm on the diagnosis error (alarm class 2).
- Set the statuses of the data received from the corresponding station to BAD.
- Use the fail-safe data values specified on the builder to replace the data values of input FBs.

When communication recovers from error, SCS will act as follows:

- Initiate a system alarm on the recovery.
- Set the statuses of the data received from the corresponding station to GOOD.
- Input FBs use the data values that are refreshed after recovery.

A6.2 Data structure and definition of the SCS link transmission

This section describes the overview of the data structure and necessary definition contents of the SCS link transmission.

Data structure of SCS link transmission

Data sent through SCS link transmission and data received from the stations are first stored in a dedicated data buffer.

When using SCS link transmission data in application logic, communication data is obtained using a dedicated input FB. Conversely, to send the result of application logic execution, the result of application logic should be input to a dedicated output FB.

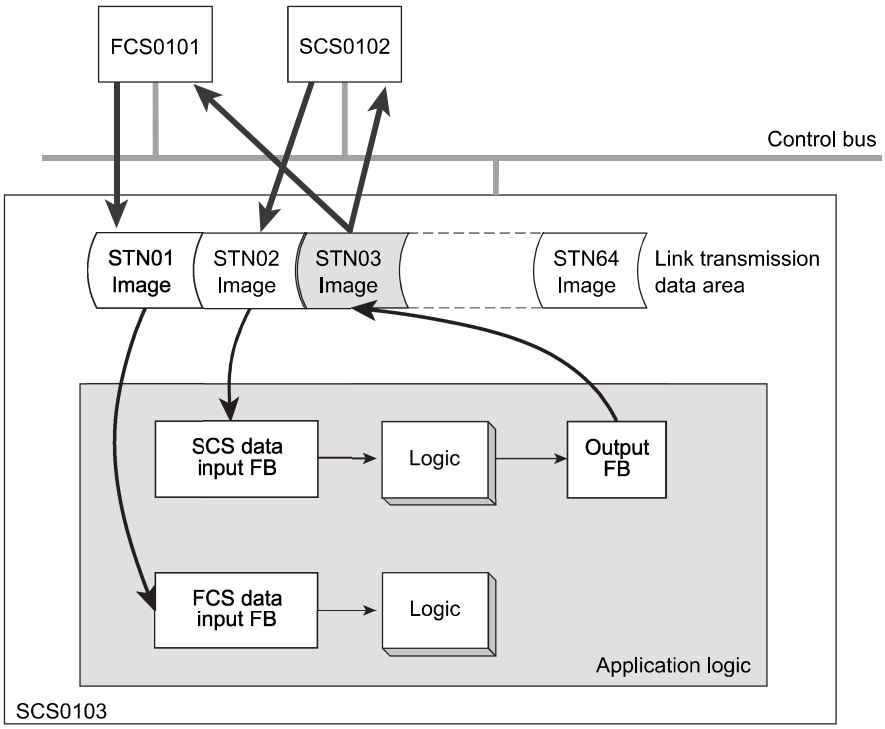

Figure A6.2-1 SCS link transmission dataflow

Receive data

Receive data of SCS link transmission consists of data value and data status. Data status in SCS link transmission does not indicate the quality of each data item, but rather gives status information regarding whether data was received normally. SCS determines data status based on the communication status and safety diagnosis result for each communication target station.

Both data value and data status can be referenced via input FB. Separate input FBs dedicated to each communicating station type (SCS/FCS) are provided.

Send data

Send data of SCS link transmission has data value only and no data status. There is only one type of output FB, regardless of whether the send destination is SCS or FCS.

Function blocks for SCS link transmission

In order for application logic to handle SCS link transmission data, the following function blocks are provided for each communicating station type.

Table A6.2-1 Function blocks related to SCS link transmission

FB type	Processing by the function block	Remark
LTRCV	Inputs link transmission data from other SCSs	Safety
LTSND	Outputs link transmission data from local SCS	
LTFCS	Inputs link transmission data sent from FCS (global switch)	Interference-free
SYS_FORCE_LT	Manages forcing of SCS Link Transmission	Safety system FB
SYS_LTSTS	Indicates SCS Link Transmission reception status	

SEE ALSO For more information about each FB, refer to:

- 6.7, “LTSND (link transmission data output)” in POU Reference Manual (IM 32P03B20-01EN)
- 6.8, “LTRCV (safety link transmission data input)” in POU Reference Manual (IM 32P03B20-01EN)
- 8.5, “LTFCS (interference-free link transmission data input)” in POU Reference Manual (IM 32P03B20-01EN)
- 11.3, “SYS_FORCE_LT (SCS link transmission lock status monitor)” in POU Reference Manual (IM 32P03B20-01EN)
- 11.6, “SYS_LTSTS (SCS link transmission reception status monitor)” in POU Reference Manual (IM 32P03B20-01EN)

Definition of send data

SCS link transmission send should be defined in SCS Link Transmission Builder and also by creating the application logic using the output FB of SCS link transmission.

Definition of SCS link transmission send

To send SCS link transmission data from an SCS to other stations, permit sending via link transmission in the Self Station tab of SCS Link Transmission Builder.

TIP At all SCSs in the domain where it is permitted to receive SCS link transmission from the station for which sending is defined, the application regarding receive data can be changed freely, and such changes do not affect other stations.

Wiring of send data

To send correct data, define an output FB in the application logic, and perform wiring definition for the local station data using SCS Link Transmission Builder.

IMPORTANT

If data with no wiring definition at the sending station is referenced at the receiving side station, data status will be GOOD and data value will be FALSE.

Definition of receive data

SCS link transmission receive should be defined in SCS Link Transmission Builder and also by creating the application logic using the input FB of SCS link transmission.

Definition of SCS link transmission receive

To receive SCS link transmission data from other stations, permit receiving via link transmission in the Self station tab of SCS Link Transmission Builder.

Data received from reception target stations are defined in the Other Stations tab of the SCS link transmission definition.

If the transmission source station type is SCS, it will be a safety communication and thus the following items must be defined. If the transmission source is FCS, it cannot be set.

- Reception Timeout (Reception interval timeout value): OUTT
- Transmission Timeout (Transmission delay timeout value): DLYT
- Pre-Alarm (Pre-alarm setting value): PALT

OUTT (reception interval timeout value) setting

The reception interval is the interval at which SCS receives the data. Specify the reception interval timeout value (OUTT) for each communication partner station. This value can be set between 3 and 30 seconds. OUTT is calculated by the following formula. However, if the calculation result is 3 seconds or less, set a value of between 3 and 30 seconds.

OUTT= (Scan period of sender SCS or receiver SCS whichever longer) x 8

If normal data cannot be received within this reception interval timeout value, a communication error will occur and the fail-safe values will be used to replace the communication data values.

Inter-SCS transmission delay time and reception interval

Inter-SCS transmission delay time is the elapsed time after the sending side SCS transmits the data until the receiving side SCS receives the data. The normal range is defined by DLYT (transmission delay timeout value). If the inter-SCS transmission delay time is outside the normal range, the received communication frame is ignored.

The transmission delay time is affected not only by the delay in the communication path but also by the difference in scan period settings of the SCS application logic execution function at the sending side and receiving side.

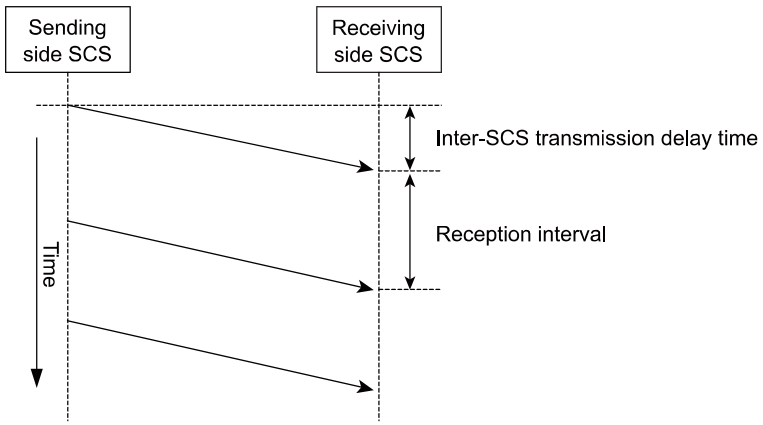

Figure A6.2-2 Inter-SCS transmission delay time and reception interval

A temporary transmission delay error can be detected by monitoring OUTT (reception interval timeout value). Set DLYT to detect a constant transmission delay error.

DLYT (transmission delay timeout value) and PALT (pre-alarm setting value) settings

- DLYT
  Specify the transmission delay timeout value (DLYT) for each communication partner station.

  DLYT can be set to 0 seconds or between 3 and 30 seconds. When DLYT is set to 0, the inter-SCS transmission delay check is disabled.

A communication error will occur if a delay outside the normal range occurs, that is, if the state where the “inter-SCS transmission delay time exceeds DLYT” continues longer than the time specified by OUTT. As a result, the fail-safe values will be used to replace the communication data values.

- PALT
  Specify the pre-alarm setting value (PALT) for each communication partner station. If it is necessary to detect transmission delay before the inter-SCS transmission delay time reaches the DLYT, specify this value. Diagnostic information message is not generated.

  PALT can be set to 0 seconds or between 3 and 29 seconds. When PALT is set to 0, the pre-alarm is not output.

  A pre-alarm will occur if the inter-SCS transmission delay time exceeds the time specified by PALT and if the state continues longer than the period specified by OUTT. By using a system function block of SYS_LTSTS, you can notify the application of the occurrence of pre-alarm.
- Relationship between DLYT and PALT
  PALT check is performed unless PALT is set to 0. Pre-alarms are detected even if DLYT is set to 0. To activate the pre-alarm while the DLYT is not set to 0, set 0 <PALT <DLYT.

IMPORTANT

If both PALT and DLYT are set to 0, the receive data of SCS link transmission cannot be used for safety purposes.

SEE ALSO

For more information about DLYT calculation method when the SCS system program release number is R2.03.51 or earlier on the sending or receiving end of SCS link transmission, refer to:

“■ Specification changes made in SCS system program (Release number R2.03.51)” in Appendix 3.2, “The major changes in R2” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Wiring of receive data

To use the receive data of SCS link transmission in application logic, define an input FB according to the station type, and then perform wiring definition of data for each receiving side station in SCS Link Transmission Builder.
During wiring definition, the input value at error occurrence should also be defined.

IMPORTANT

If wiring of the receive data from a nonexistent station is defined, the data status will always be BAD and the data value will be the input value at error occurrence.

Precaution for engineering

This section describes precautions and important issues in using SCS link transmission.

Purpose of SCS link transmission

The following figure illustrates the relationship between SCS link transmission and binding of inter-SCS safety communication for data exchange among SCSs.

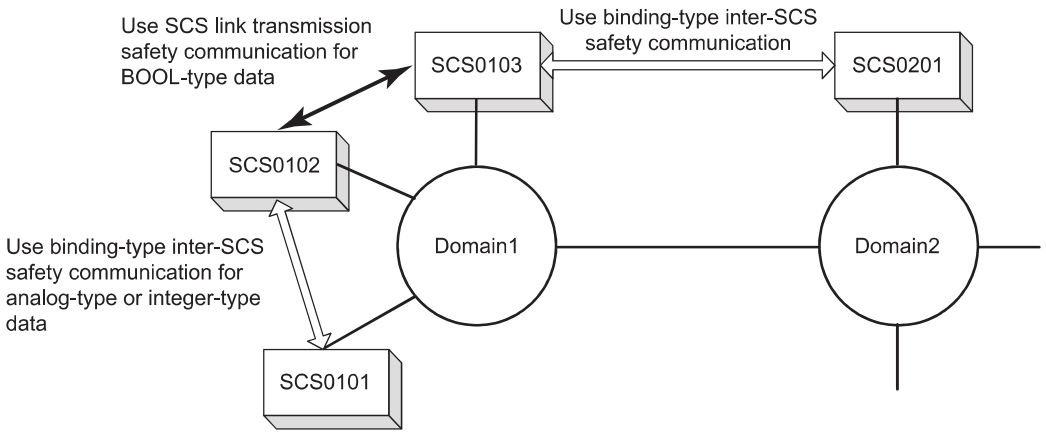

Figure A6.2-3 Relationship with Inter-SCS Safety Communication

The BOOL type data exchange among SCSs in the same domain is recommended to go through the SCS link transmission safety communication. Although the amount of data that can be communicated is limited, use of SCS link transmission safety communication enables communication with more stations and achieves higher performance, compared to when inter-SCS safety communication is used.

For analog-type or integer-type data exchange in the same domain and for inter-SCS data exchange across domains, use binding-type inter-SCS safety communication.

The following table shows the scope of communication and the relationship of communication data types and communication methods.

Table A6.2-2 Communication data types and communication methods

Scope	Data type	Communication Method	Remark
Inter-SCS in the same domain	BOOL	SCS link transmission safety communication	Can communicate with FCS (SCS global switch communication: Interference-free) Can be changed online
	Analog, integer	Binding-type inter-SCS safety communication	Cannot change the binding online
Inter-SCS across domains	BOOL, analog	Binding-type inter-SCS safety communication	Cannot change the binding online

Communication with FCS through the Inter-station Data Link Block (ADL)

FCS can read from SCS mapping blocks or write to SCS mapping blocks through the inter-station data link block (ADL). However, data exchange through SCS link transmission does not require the mapping blocks used by data exchange through inter-station data link block (ADL). Consider using SCS link transmission for SCSs exchange data of BOOL type in one domain.

The following cautions need to be noted when reading or writing for data exchange:

- When writing from FCS to SCS through the inter-station data link block (ADL), the periodic writing is restricted. However, periodic writing is possible through SCS link transmission.
- Tag names cannot be assigned for the Input/Output function block of SCS link transmission. For reading the SCS data transmitted through SCS link transmission on HIS, the transmitted data should be linked to the BOOL type internal variables by the application logics and assigned the tag names to the linked variables.

Other notices

- When the receiver station accesses data that is not assigned on the sender station, the data value will show FALSE and the data status will show GOOD.
- Builder cannot check the consistency of the data assigned on the sender station and on the receiver station for data exchange, so the assignment of the communication data on both sides must be checked by the communication test.
- By the setting of "Link Transmission Receiving Station" of SCS link transmission, the receiver stations can be limited so as to prevent the performance declination. Other stations with which no communication is required should not be specified as "Receive."
- The SCS system program for SCS that uses SCS link transmission must be R1.03.00 or later.

  The FCS system program for FCS that is the target of SCS link transmission global switch communication must be R3.08.50 or later.

SEE ALSO For more information about DLYT (transmission delay timeout value) calculation method when the SCS system program release number of either the sending or receiving end of SCS link transmission safety communication is R2.03.51 or earlier, refer to:

"■ Specification changes made in SCS system program (Release number R2.03.51)" in Appendix 3.2, "The major changes in R2" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

A6.3 SCS link transmission definition

The communication data for SCS Link Transmission can be defined on SCS Link Transmission Builder. This section explains how to define the SCS Link Transmission and how to use the SCS Link Transmission Builder.

SEE ALSO For more information about overview of definitions for SCS link transmission, refer to:

A6.1, “Overview of the SCS link transmission” on page A6-2

SCS link transmission configuration procedure

SCS Link Transmission Builder and Dictionary View are used to configure SCS Link Transmission definitions.

1. On Dictionary View, define the variable names for the SCS Link Transmission I/O FBs used for SCS Link Transmission.
2. On SCS Link Transmission Builder, define receptions and transmissions between local and other stations.
   The communicated data through SCS Link Transmission is represented by the bit number.
3. On the SCS Link Transmission Builder, define the relations of the bit numbers of each station and the variable names of the SCS Link Transmission I/O FBs.

Main features of SCS Link Transmission Builder

On the SCS Link Transmission Builder, the variables to be received and to be transmitted through SCS Link Transmission can be assigned and their connections with SCS Link Transmission I/O FBs can be wired.

Through wiring these elements, bit numbers of each station are associated with the variable names of SCS link transmission I/O FBs. The SCS Link Transmission I/O FBs that can be assigned to the bit numbers of SCS Link Transmission vary with the station type of the destined stations.

The station types of the destined Other Stations are:

- SCS
- FCS, GSGW, and APCS
  Other Stations such as FCS, GSGW, and APCS are referred as FCS.

Start SCS Link Transmission Builder

1. Choose [Engineering] from [Tools] menu of SCS Manager.
   The Engineering Launcher menu appears.
2. Click [SCS Link Transmission Builder].
   The SCS Link Transmission Builder starts.

SCS Link Transmission Builder window

In the left pane of SCS Link Transmission Builder window, the following contents are listed. After selecting content from the list, the corresponding details will be displayed in the right pane.

- SCS Link Transmission Definition
- Data Wiring Definition
- Data Wiring View

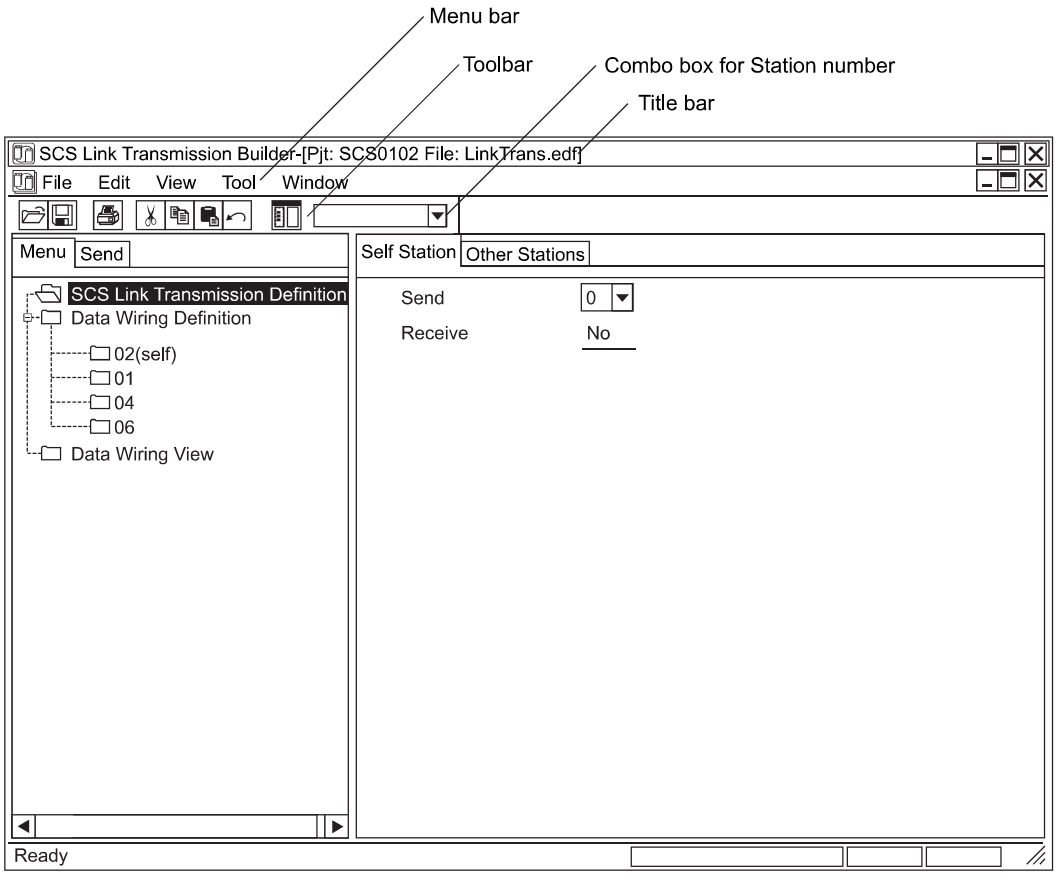

Figure A6.3-1 SCS Link Transmission Builder - SCS Link Transmission Definition - "Self Station" Tab

Self Station tab of SCS link transmission definition

On this tab, the data reception and transmission of the local station can be defined.

Send

Whether to send data from the local station can be defined. If you want to send data from the local station, choose [1: Yes], otherwise choose [0: No]. When [1: Yes] is chosen, the related wirings on the local station need to be defined. The initial setting is "No."

IMPORTANT

When "No" is chosen for Send, the previously defined wiring information will be removed at the moment of switching tabs.

Receive

Whether to receive data from other stations can be defined. If you want to receive data from other stations, choose [1: Yes], otherwise choose [0: No]. When [1: Yes] is chosen, the related settings on "Other Stations" tab need to be defined. The initial setting is "No."

IMPORTANT

When "No" is chosen for Receive, the previously defined wiring information will be removed at the moment of switching tabs.

Other Stations tab of SCS Link Transmission Definition

When Receive is set to [Yes] on "Self Station" tab of SCS Link Transmission Definition, the station type, the reception interval timeout (OUTT), the transmission delay timeout (DLYT), and the pre-alarm setting value (PALT) need to be defined for each station.

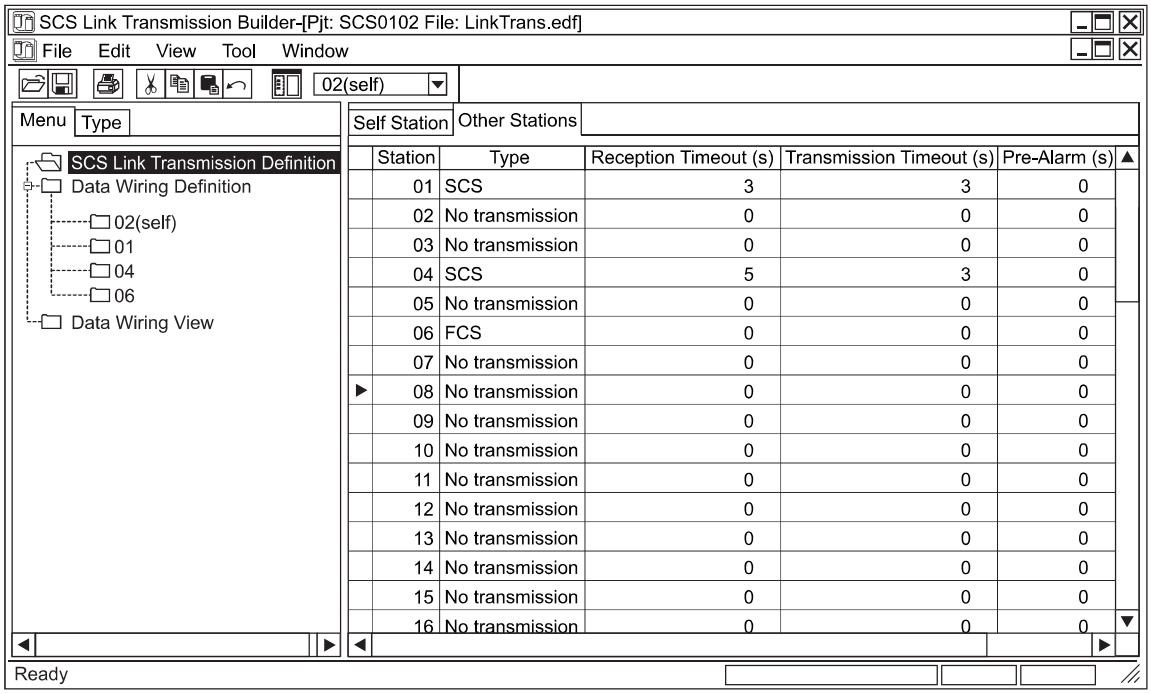

Figure A6.3-2 Other Stations tab of SCS Link Transmission Definition on SCS Link Transmission Builder

Type

The numbers in the "Station" column at left side are the station numbers. The type needs to be set according to each station number. For receiving the SCS Link Transmission data, the type should be set to [1: SCS], while for receiving the global switches of FCS, the type should be set to [2: FCS]. [0: No transmission] can also be set if not receiving data from that station.

IMPORTANT

- The type for the local station should not be set. If you set it, an error will occur during build operation.
- When "No transmission" is set for Type, the previously defined wiring information of that station will be removed at the moment of switching tabs.

Reception Timeout (Reception interval timeout value)

The reception timeout should be set to a time between 3 and 30 seconds. This setting is required for the SCS type only. The initial setting is 3 seconds.

Transmission Timeout (Inter-SCS transmission delay timeout value)

The transmission timeout, i.e. the limited time from transmission to reception should be set to a time between 3 and 30 seconds. This setting is required for the SCS "Type" only. The initial setting is 3 seconds.

If the inter-SCS transmission delay check is not required, "0" should be set. However, if "0" is set, the received data cannot be used for Safety loop logic.

Pre-Alarm (Pre-Alarm setting value)

The pre-alarm can be initiated prior to transmission timeout alarm. The time for initiating the pre-alarm can be set to 0 or from 3 to 29 seconds. This setting is required for the SCS type only. The pre-alarm setting value should be set if you need to detect transmission delay before the delay reaches the transmission delay timeout value (DLYT). The initial setting is "0".

SEE ALSO For more information about defining incoming data for SCS link transmission, refer to:

A6.2, “Data structure and definition of the SCS link transmission” on page A6-5

For more information about precautions regarding the setting times for SCS link transmission, refer to:

“■ Precaution for engineering” on page A6-8

Data Wiring Definition

Wiring details for both "Self Station" and "Other Stations" need to be defined.
The Data Wiring Definition of the tree view in the left pane and the tab in the right pane show the following station numbers.

- The station number of the Self Station When the setting of Send in the "Self Station" tab of SCS Link Transmission Builder is set to "Yes."
- The station numbers of the other stations When the setting of Receive in the "Self Station" tab of SCS Link Transmission Builder is set to "Yes" and the setting of Type in the "Other Stations" tab of SCS Link Transmission Builder is set to "SCS" or "FCS."

Do the following to switch the tabs from "Self Station" and "Other stations."

- Choose a station number in the tree view in the left pane.
- Select a station number in the combo box for selecting the station on the toolbar.

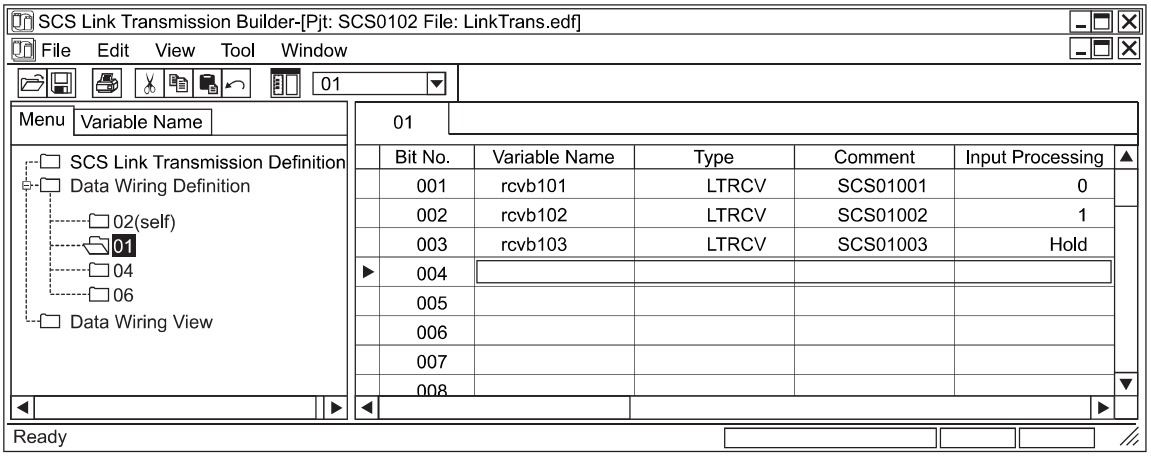

Figure A6.3-3 Other Stations tab of Data Wiring Definition on SCS Link Transmission Builder (SCS)

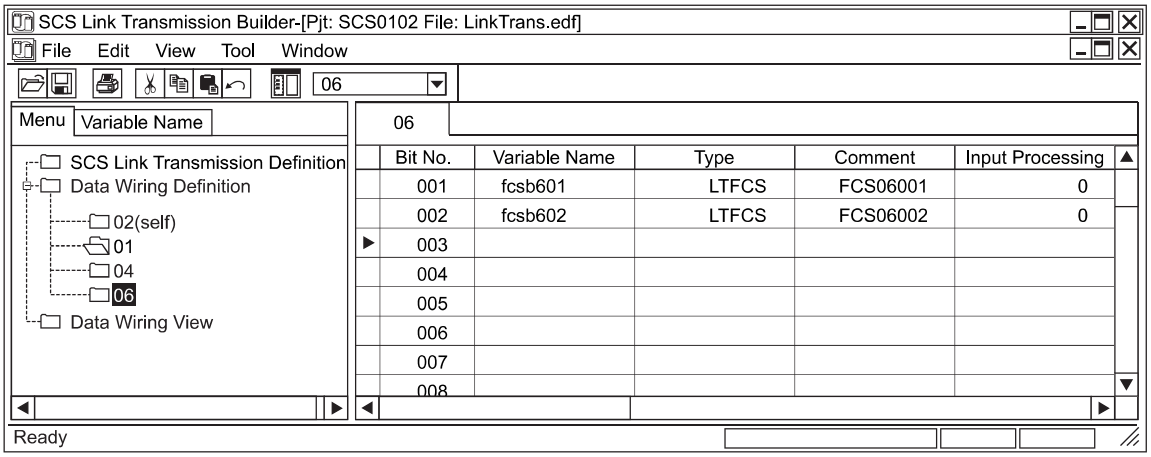

Figure A6.3-4 Other Stations tab of Data Wiring Definition on SCS Link Transmission Builder (FCS)

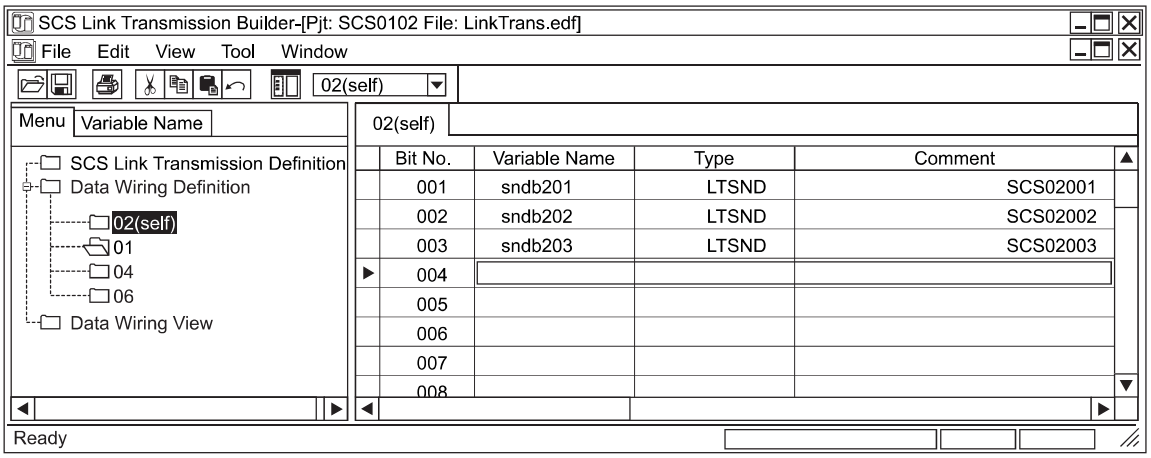

Figure A6.3-5 Self Station tab of Data Wiring Definition on SCS Link Transmission Builder

Bit No. (Bit number)

Shows the bit numbers in the SCS link transmission data area used for SCS Link Transmission. This number is not editable.

For SCS, the bit numbers are in the range of 001 to 128. For FCS, the range is 001 to 256.

Variable Name

Do any of the followings to set the instance name of SCS Link Transmission input/output FB to each variable name.

- Enter the variable name directly.
- Double-click a variable name displayed in the "Variable Name" tab in the left pane.
- Drag a variable name from Dictionary View and drop it into the Variable Name field.

A variable name can contain up to 69 single-byte characters.

To globally identify an internal variable that has been declared as a local variable, affix an @ character and scope name to the variable.

For accessing the internal variable of a user-defined function block, the user-defined function block itself should be assigned with an instance name on Dictionary View. Then the variable name becomes "<Instance Name>.<Internal Variable Name>." The variable can be accessed through two nests.

SCS Link Transmission Builder checks the following items:

- The variable name consists only of alphanumeric characters and "@", "." or "_". If any other character is used, an error will occur.
- The variable name begins with an alphabetic character or "_," otherwise, an error will occur.
- If the number of nests is three or more, an error will occur.
  For example, the variable name FB01.VAR3@PROG1 (Internal variable VAR3 of a user-defined function block instance FB01 in PROG1) has one nest; the instance "FB01.FB02.VAR3" (Internal variable VAR3 of a user-defined function block instance FB02 used in the user-defined function block instance FB01) has two nests.

  The selectable variables vary with the station types. The SCS Link Transmission I/O FBs for the variables corresponding to the station types are as follows:

Table A6.3-1 Station types and SCS Link Transmission I/O FBs

Station Type	SCS Link Transmission I/O FB
Self Station	LTSND (Link Transmission Data Output FB)
Other Station (SCS)	LTRCV (Safety Link Transmission Data Input FB)
Other Station (FCS)	LTFCS (Interference-free Link Transmission Data Input FB)

When setting a variable name from Dictionary View, the procedure is as follows.

Drag a variable name from Dictionary View and then drop it into the Variable Name field of Link Transmission Builder. Variable names can be specified for Link Transmission Builder. When dragging multiple variable names, they will be dropped from the beginning field. The existing variable names in the fields will be overwritten.

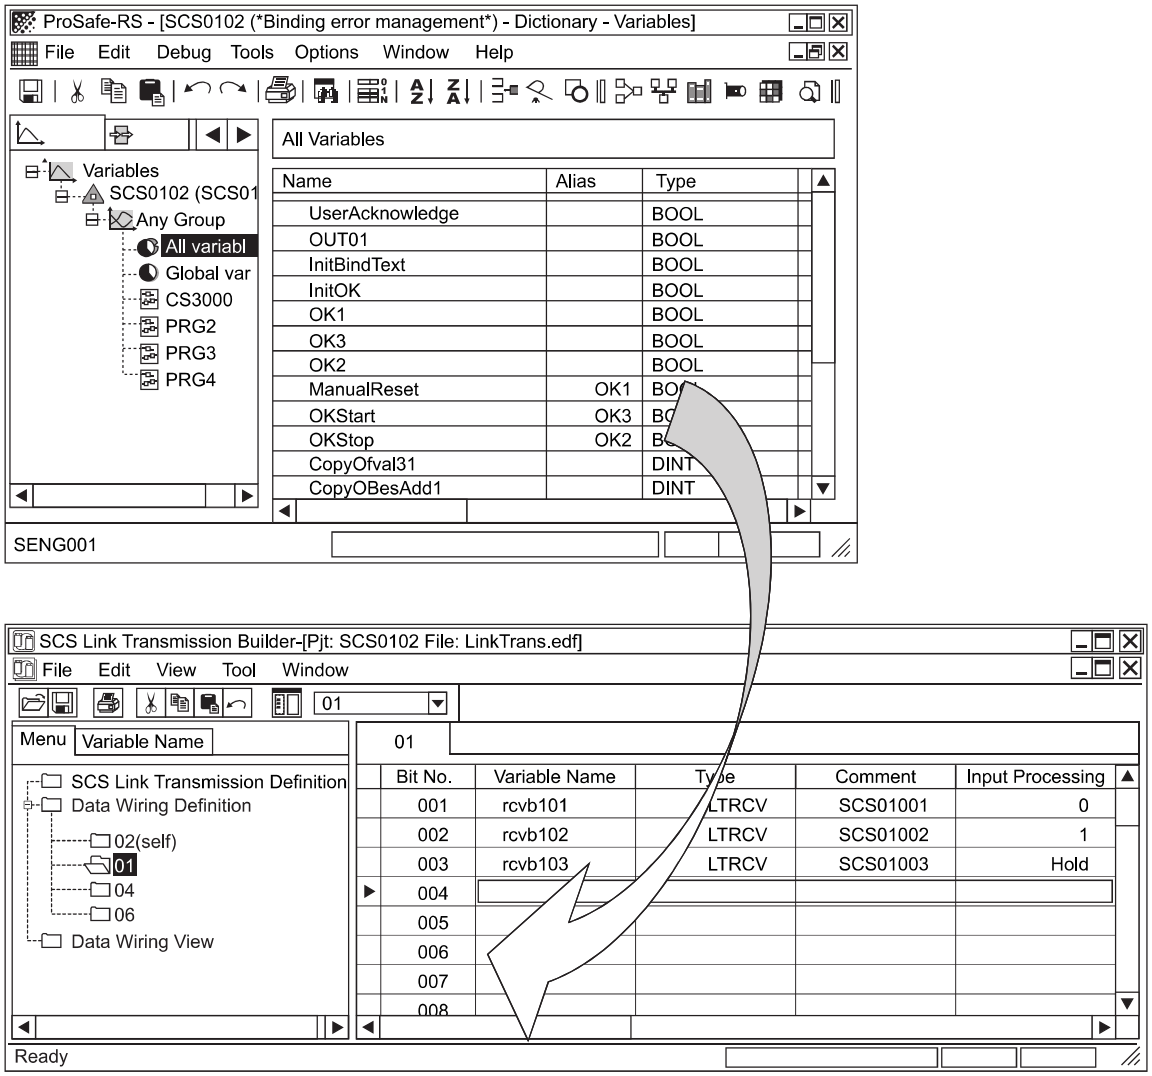

Figure A6.3-6 Drag and drop from Dictionary view

Type

Displays the SCS Link Transmission I/O FB types corresponding to the station type. This item is not editable.

Comment

Displays the comment of the variable. This item is not editable.

Input processing at fault

When a data's status becomes BAD, a predefined value can be set to the logic data. This is valid only when "Other Stations" is selected.

The input value to be set to the data at error occurrence is selectable from the following options, [0],[1] or [2]. The initial setting is 0.

Table A6.3-2 Input processing at fault

Option	Setting Value	Description
0	0	Set the input data to 0 when the input becomes error.
1	1	Set the input data to 1 when the input becomes error.
2	Hold	Hold the current value when the input becomes error.

Wiring View

Shows the list of Data Wiring Definition.

In this window, the wiring definitions are displayed with the format where the Self-Station is placed at the first and followed by Other Stations sorted by bit numbers. All data of the local station and up to 1000 data of the other stations can be displayed. This window is not editable.

Double-clicking a variable name, the Data Wiring Definition window regarding the variable will be displayed.

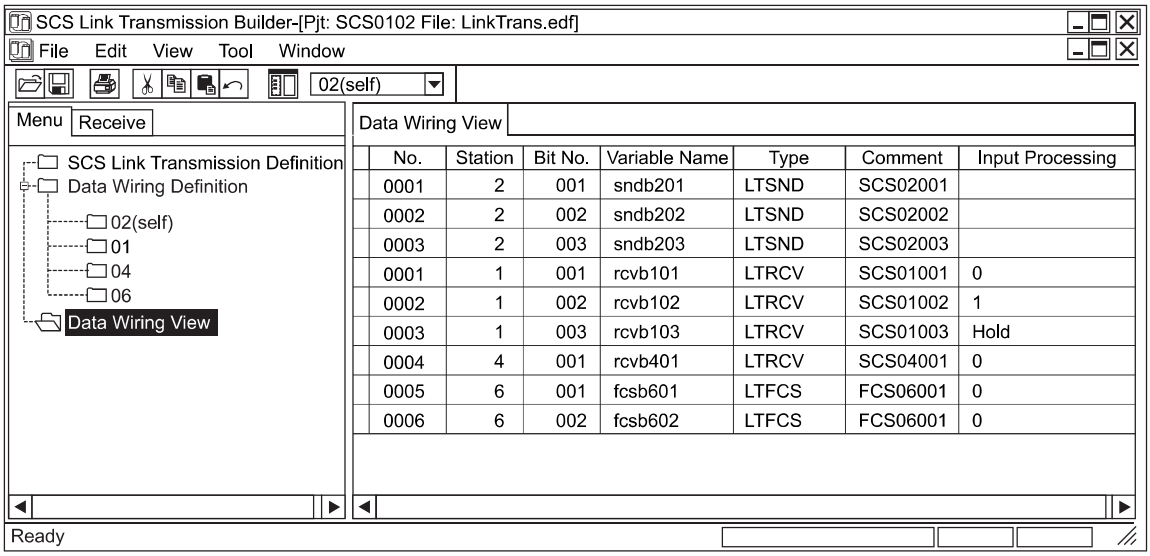

Figure A6.3-7 Data Wiring View on SCS Link Transmission Builder

Notes on reusing data defined by SCS Link Transmission Builder

In the following operation, the settings for the SCS Link Transmission Definition and the settings for wiring must be edited.

- Importing the 'data that was set to Station A for Link Transmission' to Station B
- In the SCS Project Properties dialog box, changing the station number of the SCS project from A to B

Notes for importing data and notes for changing station number are the same. Notes for importing SCS Project are given below.

The status of the imported data after SCS Link Transmission Builder saves them is as follows:

- The content of the SCS Link Transmission Definition settings is the exported data from Station A.
- The data for 'Self Station' tab in the Wiring Definition settings exported from Station A is automatically set to the 'Self Station' tab data for Station B. The contents of other stations remain unchanged.

IMPORTANT

Even if the exported SCS Project has a different Station type (SCS or FCS) in the Link Transmission Definition settings from the importing SCS Project, only the message meaning 'The data being edited will be lost. OK?' appears. Note that no dialog box to confirm the change in the Station type will appear.

An example of exporting data from Station A (SCS0101) and importing it to Station B (SCS0102) is shown below.

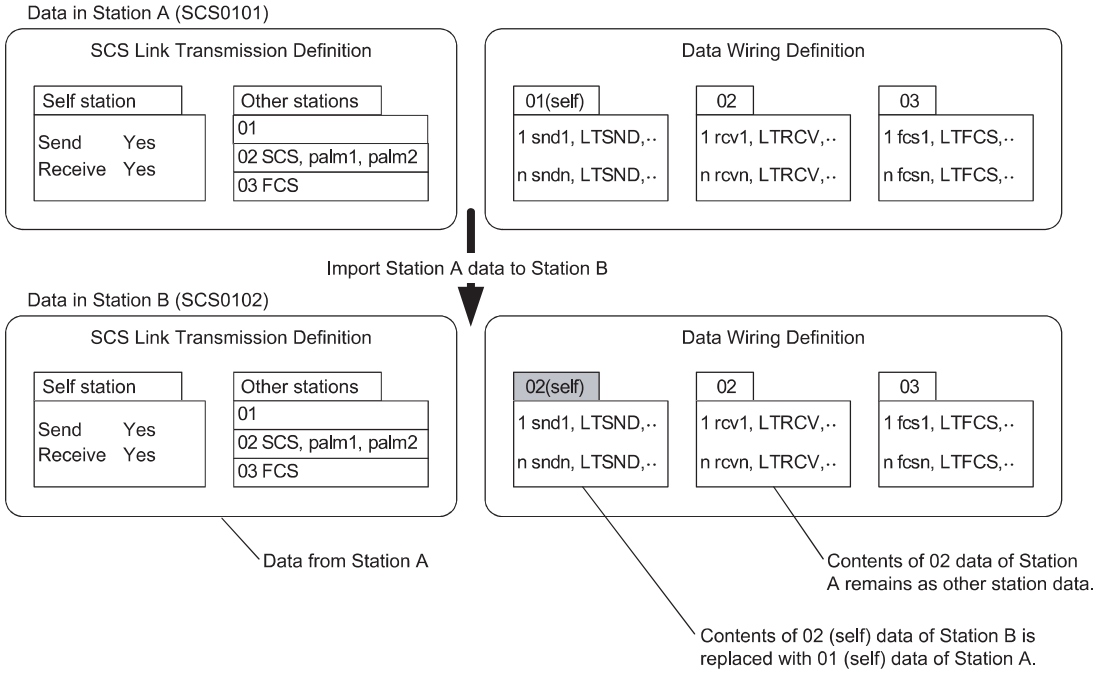

Figure A6.3-8 Example of importing Station A (SCS0101) Data to Station B (SCS0102)

As shown in the previous figure, the "Self Station" tab data of Station B (SCS0102) is replaced with the "Self Station" data in Wiring Definition settings of Station A (SCS0101).

If the Link Transmission Definition settings and Wiring Definition settings with Station B are made in Station A, the Link Transmission Definition settings and Wiring Definition settings in Station B will remain as "Other Station" data after the import.

If one station number is defined as both "Self Station" and "Other Station" an error is raised at a build. To avoid this, follow the steps below.

If the old Station B data is not needed,

1. After importing the Station A data to Station B, delete the Station B ("02" in the example) that is defined as "Other Station" in the SCS Link Transmission Definition settings of Station B and save the changes.
2. In the Dictionary View, delete related variables.
3. Edit the contents of the SCS Link Transmission Definition settings and Wiring Definition settings.

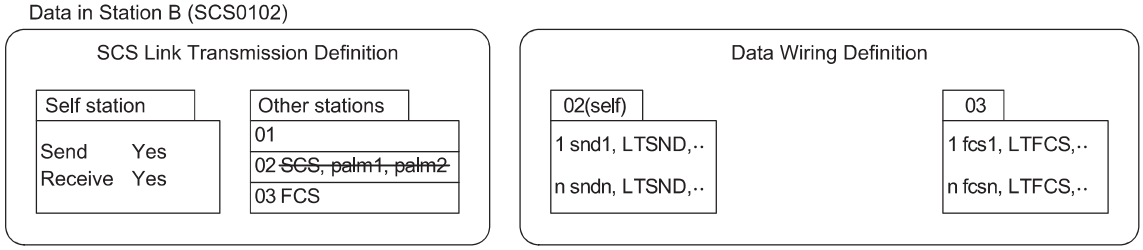

Figure A6.3-9 Case where the old Station B data is not needed

If the old Station B data needs to be saved,

1. After importing the Station A data to Station B, define a new station ("04" in the example) to move the Station B data that was defined as Other station ("02" in the example) in SCS Link Transmission settings to.

2. In Wiring Definition settings, copy the Station B data and paste it to the newly defined station.

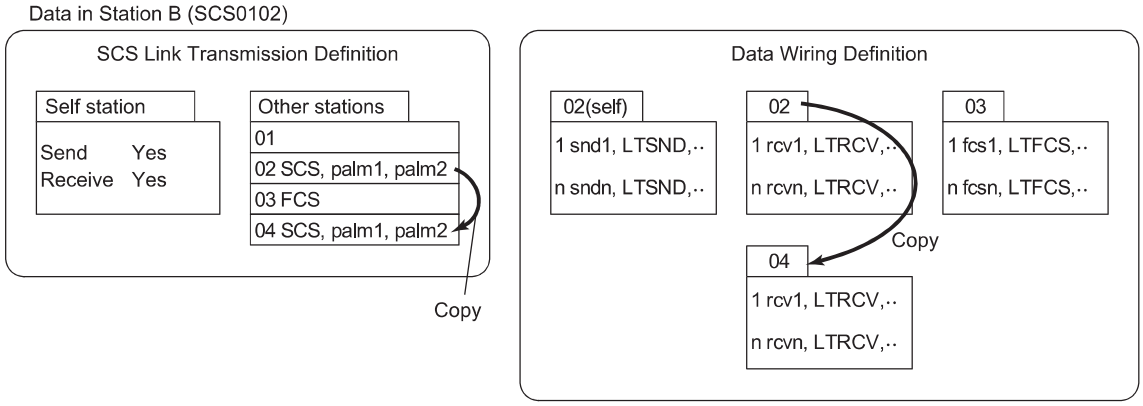

Figure A6.3-10 Data transfer when Station B data needs to be saved

3. In the SCS Link Transmission Definition settings, delete the Station B that is defined as Other station ("02" in the example) and then save the changes.
4. Edit the related variables in the Dictionary View if necessary.
5. Edit the contents of the SCS Link Transmission Definition settings and Wiring Definition settings.

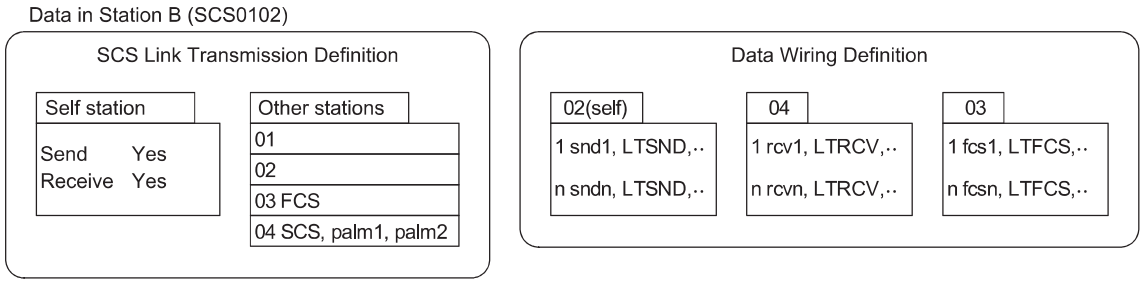

Figure A6.3-11 Structure when the old Station B data needs to be saved

A6.4 Actions taken for SCS link transmission when SCS is unsteady

This section explains the actions taken for SCS link transmission safety communication when the SCS is unsteady, as well as the operation at a SCS link transmission error occurrence.

SEE ALSO For more information about behavior of SCS global switch communication when the SCS is unsteady, refer to:

A6.5, “SCS global switch communication” on page A6-24

SCS link transmission safety communication during SCS startup

During SCS startup, SCS link transmission safety communication is processed in the following manner.

Start of reception

When the SCS is started, reception of SCS link transmission starts.

Start of sending and status of data

Even when the SCS is started, if the output enable operation is not performed, SCS link transmission data will not be sent. In this case, logical data of the receiving side link transmission data area will be the input value at error occurrence specified in [Input Processing at Fault] item of Data Wiring Definition in SCS Link Transmission builder (FALSE if specified as HOLD). The data status will be BAD.

When the output enable operation is performed at the sending side SCS, sending of data starts and logical data of the receiving side SCS's link transmission data area will be the value sent by the sending side SCS, and the data status will be GOOD.

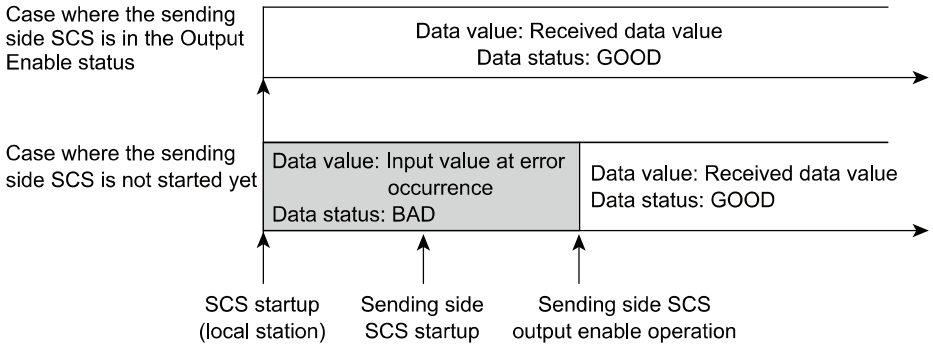

Figure A6.4-1 SCS link transmission safety communication receive data during SCS startup

TIP After the output enable operation is performed, sending of SCS link transmission will not be placed in the Output Disable status until the SCS is stopped.

Notification of errors and recovery during SCS startup

During the SCS startup, errors related to SCS Link Transmission are handled as follows:

- During the SCS startup, no diagnostic information message on SCS Link Transmission errors will be sent. After the error status during the startup turns to normal, diagnostic information message on errors will be sent at the error occurrence.
- No diagnostic information message notifying recovery from errors of SCS Link Transmission that occurred during the SCS startup will be sent.

Diagnosis of SCS link transmission safety communication

During inter-SCS link transmission safety communication, the following diagnoses are performed.

- The receiving side SCS checks if correct data is received within the reception interval timeout value (OUTT). If a timeout occurs, it is judged that a communication error has occurred. Until then, the last normal value is retained.
- In addition to the setting data, the sending side SCS appends data to guarantee communication quality and sends the data to the communicating SCS. The receiving side SCS performs various verifications to confirm validity of data sent by the sending side SCS. If the result of verification indicates abnormality, it is judged that a communication error has occurred.

Processing upon SCS link transmission safety communication error

When the result of SCS link transmission safety communication diagnoses indicates an error, the following processing takes place.

Receive data/data status

- Logical data of the link transmission data area received will be set according to the specified input value at error occurrence defined in the Data Wiring definition of SCS Link Transmission Builder.
- The data status will be BAD.

The data and data status above are output from the LTRCV function block.

Notification of communication error

A diagnostic information message indicating "Diagnostic Error" will be sent from each receiving station where a communication error has occurred. However, no diagnostic information message notifying errors related to SCS Link Transmission will be sent during the SCS start-up.

SEE ALSO For more information about diagnostic information messages, refer to:

Message Number 4133 in 2.1, “System Alarms (Message Numbers 4101 through 4222)” in Messages Reference Manual (IM 32P02B10-01EN)

Processing upon recovery from SCS link transmission safety communication error

After the cause of communication error is removed and receive data from the SCS becomes normal, the error condition recovers automatically. If latching the data at communication error is necessary, write the data latching logic in application logic.

Receive data/data status

- Logical data of the link transmission data area received will be the value sent by the sending side SCS.
- The data status will be GOOD.

The data and data status above are output from the LTRCV function block.

Notification of recovery from communication error

A diagnostic information message indicating "Recovery from Diagnostic Error" will be sent from each receiving station where a communication error has been recovered. However, no diagnostic information message related to SCS Link Transmission notifying the recovery from the errors that occurred during the SCS startup will be sent.

SEE ALSO For more information about diagnostic information messages, refer to:

Message Number 4134 in 2.1, “System Alarms (Message Numbers 4101 through 4222)” in Messages Reference Manual (IM 32P02B10-01EN)

SCS link transmission during switching of CPU control right

Switching the control right of a dual-redundant CPU module does not affect the receive data.

SCS link transmission during error at one side of control bus

An occurrence of error at one side of control bus does not affect the receive data.

A6.5 SCS global switch communication

By using SCS global switch communication of the SCS link transmission function, data can be sent and received between a CENTUM station (FCS, APCS, and GSGW, hereafter collectively referred to as FCS) and an SCS.

A6.5.1 Referencing FCS data from SCS

When sending of global switch value to other stations is permitted at an FCS, values set from %GS001 to %GS256 at the FCS can be received at an SCS as BOOL-type data.

Referencing FCS data

The LTFCS function block is used to reference FCS %GS data. LTFCS is an interference-free function block. It cannot be used for safety loop.

Data referenced with the LTFCS function block is defined by wiring the link transmission data area and LTFCS function block in SCS Link Transmission Builder.

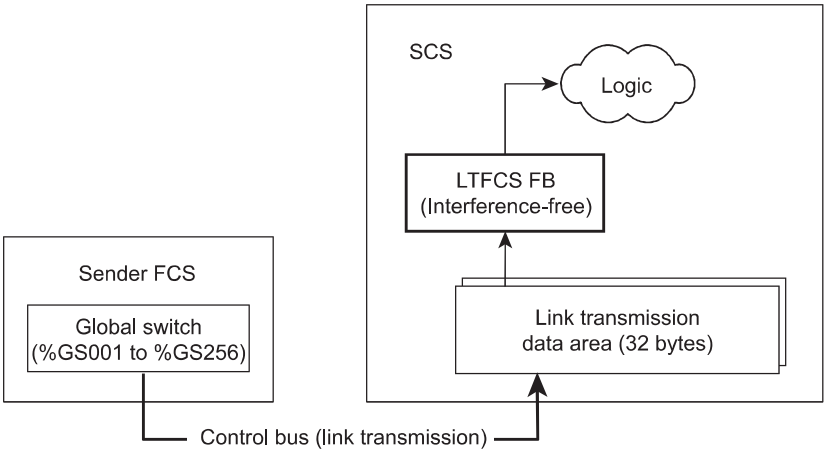

Figure A6.5.1-1 Referencing FCS data

Data check using CENTUM

- For data set to an SCS from an FCS, check global switch data of the FCS.
- To check the data received at an SCS from CENTUM stations, connect BOOL data to GSV parameter of the LTFCS function block and give a tag name to the BOOL data.
- To check the status of data received at an SCS from CENTUM stations, connect BOOL data to STS parameter of the LTFCS function block and give a tag name to the BOOL data.

Diagnosis of communication error

The communication status with an FCS is checked at an SCS. Regardless of the scan period of SCS application logic, if data update from the FCS stops for 3 seconds, the SCS judges that a communication error has occurred and starts the input processing at fault. Possible causes of communication error are shown below.

- The sending side FCS failed.
- Control bus failed on both bus 1 and bus 2.

Processing upon communication error

If a SCS global switch communication error, including the sending side FCS stop, has occurred, the SCS starts the input processing at fault.

Receive data/data status

- Logical data of the link transmission data area received by the SCS will be set depending on the input value at error occurrence defined on the Data Wiring definition of SCS Link Transmission Builder.

- The data status will be BAD.

The data and data status above are output from the LTFCS function block.

Notification of communication error

A diagnostic information message indicating "Diagnostic Error" will be sent from the SCS. However, no diagnostic information message notifying errors related to SCS Link Transmission will be sent during the SCS startup.

SEE ALSO For more information about diagnostic information messages, refer to:

Message Number 4133 in 2.1, “System Alarms (Message Numbers 4101 through 4222)” in Messages Reference Manual (IM 32P02B10-01EN)

Processing upon communication error recovery

After the cause of communication error is removed and the receive data from the FCS becomes normal, the error condition recovers automatically. If latching the data at communication error is necessary, write the data latching logic in application logic.

Receive data/data status

- Logical data of the link transmission data area received by the SCS will be the %GS value sent by the FCS.
- The data status will be GOOD.

The data and data status above are output from the LTFCS function block.

Notification of recovery from communication error

A diagnostic information message indicating "Recovery from Diagnostic Error" will be sent from the SCS. However, no diagnostic information message related to SCS Link Transmission notifying the recovery from the errors those occurred during the SCS startup will be sent.

SEE ALSO For more information about diagnostic information messages, refer to:

Message Number 4134 in 2.1, “System Alarms (Message Numbers 4101 through 4222)” in Messages Reference Manual (IM 32P02B10-01EN)

A6.5.2 Data setting from SCS to FCS

If reception of global switch values from other stations is permitted at an FCS, data from the link transmission data area of an SCS can be received by the FCS as global switch data %GS001 to %GS128. The data received at FCS from %GS129 to %GS256 are meaningless and thus should not be referenced on the FCS side.

FCS data setting

The LTSND function block is used for setting data to an FCS. Input the BOOL-type data to be sent to the LTSND function block, and perform wiring between the LTSND function block and link transmission data area in SCS Link transmission builder.

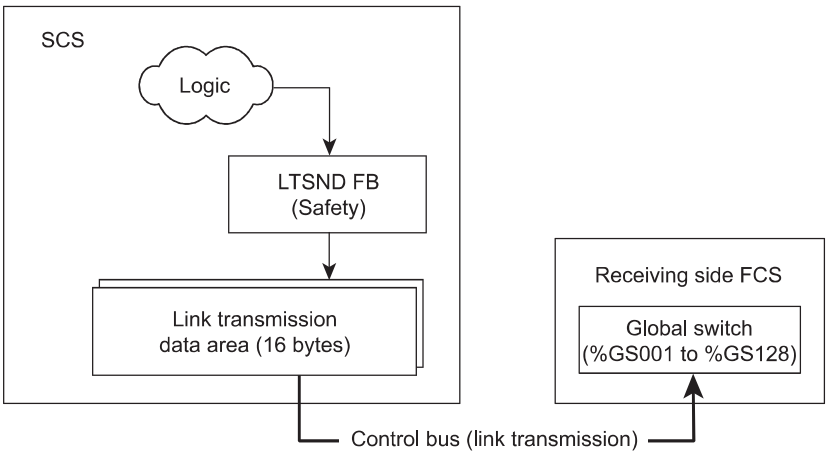

Figure A6.5.2-1 FCS data setting

SEE ALSO For more information about flow of engineering procedures, refer to:

"■ SCS link transmission" on page B7-32

For more information about engineering functions required for engineering, refer to:

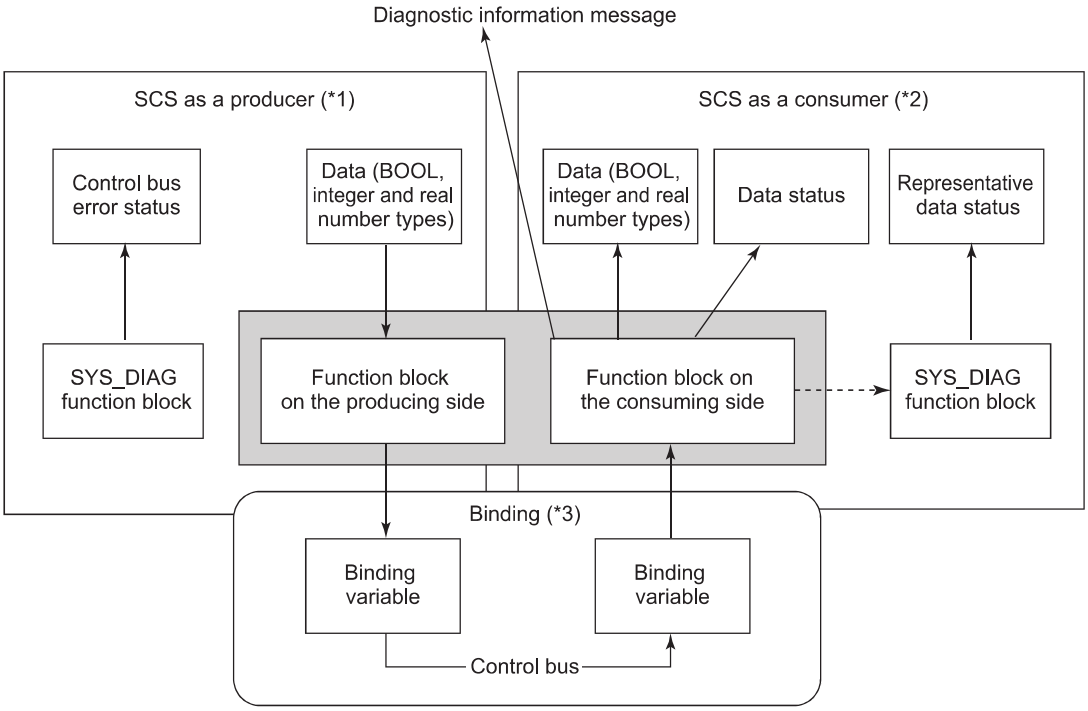
A6.3, "SCS link transmission definition" on page A6-11

For more information about precautions regarding FCS data setting, refer to:

A6.1, "Overview of the SCS link transmission" on page A6-2

When SCS is in the Output Disable status

When the data sending side SCS is in the Output Disable status, %GS of the FCS is set to 0 and the data status will be BAD.



After the SCS output enable operation is performed, data specified in SCS Link Transmission Builder will be set to %GS and the data status will change to GOOD.

A7. Inter-SCS safety communication

An SCS is able to perform safety communication with other SCSs in the same domain as well as in different domains. This means that the user can create a safety-loop covering two SCSs.

Structure of Inter-SCS safety communication function

The following figure shows an overview of Inter-SCS safety communication.

*1: An SCS that creates and sends a binding variable
*2: An SCS that receives and reads the binding variable
*3: A mechanism for passing a binding variable of the SCS on the producing side to the SCS on the consuming side

Figure A7-1 Overview of inter-SCS safety communication

Outline of the inter-SCS safety communication

In ProSafe-RS, it is possible to perform the Inter-SCS safety communication in the same control bus domain or in different control bus domains. The inter-SCS safety communication is a one-way communication of one-to-one variable between SCSs. The inter-SCS communication can be used to build the safety loop between SCSs.

To perform the Inter-SCS safety communication, the application logic using the dedicated FB is generated in each SCS of the sender and the receiver. Variables called binding variable are used to bind each variable of the sender and the receiver.

The following example explains the inter-SCS safety communication which sets BOOL variable X to variable Y.

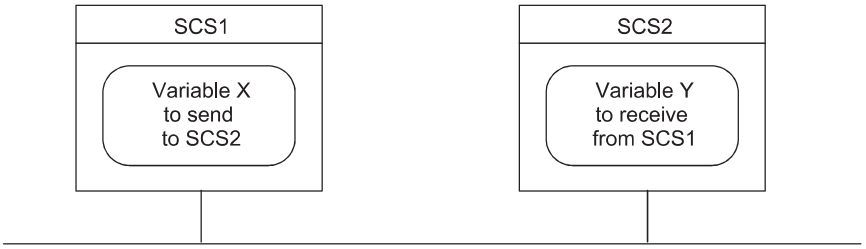


Figure A7-2 An example of a project

Generate FB (PROD_B, PROD_I, PROD_R) for communication on the sender side (the producer) in SCS, and FB (CONS_B, CONS_I, CONS_R) for communication on the receiver side (the consumer) in SCS in order to implement this Inter-SCS safety communication. To connect the sender and the receiver, define the binding variables ("P0101001" and "C0101001" in the figure shown below) for each side.

The binding variables in pairs are connected in Binding List View.

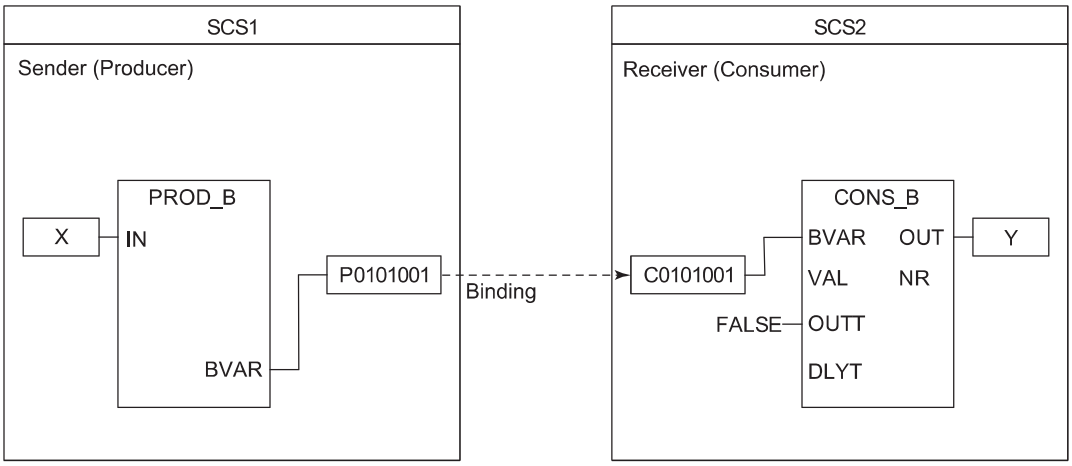

Figure A7-3 Inter-SCS communication application

The following status indicates how the Inter-SCS safety communication is performed.

- Control bus fault status indicating whether or not the SCS (the producer, the consumer) is communicable.
- Data status and Representative data status showing that data can be received normally (the consumer)
- Diagnostic information message about communication error and recovery (the consumer)

Several data sent in the same scan timing from the producer are certainly received in the same scan timing in the consumer.

SEE ALSO For more information about how to define inter-SCS communication, refer to:

A7.1, "Inter-SCS safety communication definition" on page A7-12

Mechanism of inter-SCS safety communication

Inter-SCS safety communication is achieved by function blocks dedicated for inter-SCS safety communication. The function block on the producing side sends setting data as well as data for guaranteeing communication quality to the communicating SCS via the control bus. The communication path can be between SCSs in the same domain or SCSs in different domains. In a configuration with CENTUM integration, inter-SCS safety communication can be performed while CENTUM devices are connected to the same control bus. The function block on the consuming side performs various tests on received data to check the validity and only outputs data whose quality can be guaranteed. If data is judged to be incorrect as a result of

these tests, the fail-safe value preset on the consuming side is output. Make sure to create an application logic to be used when data is not correct.

IMPORTANT

The output enable operation is required in order for the SCS on the producing side to perform transmission. The function block on the consuming side outputs the specified fail-safe values and communication status (parameter NR) becomes abnormal (FALSE) until the output enable operation is performed.

SEE ALSO

For more information about BOOL-type data reception, refer to:

6.4, “CONS_B (inter-SCS safety communication BOOL-type data consumer)” in POU Reference Manual (IM 32P03B20-01EN)

For more information about DINT-type data reception, refer to:

6.5, “CONS_I (inter-SCS safety communication INTEGER-type data consumer)” in POU Reference Manual (IM 32P03B20-01EN)

For more information about REAL-type data reception, refer to:

6.6, “CONS_R (inter-SCS safety communication REAL-type data consumer)” in POU Reference Manual (IM 32P03B20-01EN)

Operation when launching inter-SCS safety communication

- The function block on the consuming side outputs the fail-safe values predefined in the function block, until the SCS on the producing side starts sending data and the function block on the consuming side is ready to correctly receive the data sent by the SCS on the producing side. The communication status (parameter NR) remains abnormal (FALSE) during this period.
- When you start up the SCS on the producing side and perform the output enable operation, inter-SCS safety communication starts sending data. Once the sent data is successfully received by the SCS on the consuming side, the function block on the consuming side will output the received data and the communication status will change to normal (TRUE).

Operations at inter-SCS safety communication errors

If a communication error occurs during inter-SCS safety communication, the following operations are performed.

- The fail-safe value preset on the function block for inter-SCS safety communication on the consuming side is output.
- The communication status (parameter NR) becomes abnormal (FALSE).
- A diagnostic information message notifying about the error is output.

The following operations are performed if the system recovers from a communication error.

- The data value received from the producing side is output from the function block on the consuming side.
- The communication status (parameter NR) becomes normal (TRUE).
- A diagnostic information message notifying about the recovery is output.

The following table shows the operations that are performed for each error status.

Table A7-1 Operations at communication errors

Status	Output on the consuming side	Remarks
The SCS on the producing side has stopped	The previous value is retained after the communication stops. After the reception interval timeout period is exceeded, the fail-safe value is output.	Start up the SCS on the producing side and perform the output enable operation to restore communication.
An error has occurred in the communication path and communication has stopped for a long period	Same as above. The data value is output when the communication is resumed.	-
An error has occurred in the communication path and communication has stopped temporarily	The previous value is retained while the communication is stopped. The data value is output when the communication is resumed.	This applies when communication is resumed within the reception interval timeout period
An error has occurred in the communication path and the contents of the communication have been destroyed	The previous value is maintained as long as the communication data is corrupted. The data value is output when correct data is received.	The fail-safe value is output if the communication data is corrupted for longer than the reception interval timeout time.
There is a delay in the communication path and communication is very slow	The fail-safe value is output if the communication is delayed more than the transmission delay timeout period. The data value is output when the communication is resumed. The transmission delay is not checked if the transmission delay timeout value is set to 0.	-
Erroneous engineering is performed.	The fail-safe value is output and a diagnostic information message is output.	When a wrong binding variable name is used.

Precaution for engineering

This section describes precautions and important issues in using the Inter-SCS safety communication.

Communicable extent

Safety communication that guarantees the safety of SIL3 or SIL2 for the SCS used is possible between the SCSs in Vnet/IP domains and the V-net domains. Even if control communication and open communication coexist on the Vnet/IP network, safety of SIL3 or SIL2 is guaranteed.

SEE ALSO For more information about precautions when SCS in V-net is included in the route of inter-SCS safety communication, refer to:

Appendix 4.2, “Inter-SCS safety communication in a V net domain” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Inter-SCS safety communication capacity

The number of data handled in Inter-SCS safety communication is as follows:

- The maximum number of data that one SCS can send is up to 200.
- The maximum number of data that one SCS can receive is up to 200.

The number of binding connections in each SCS should be 16 or less. This number is a total of connections from both sender and receiver.

- Connections on the sender side
  This is the number of all consumer binding groups that are mapped to all binding groups defined as producers on the local SCS.

- Connections on the receiver side
  This is the number of all binding groups that are defined as consumers on the local SCS.

The following figure shows how to calculate the number of binding connections.

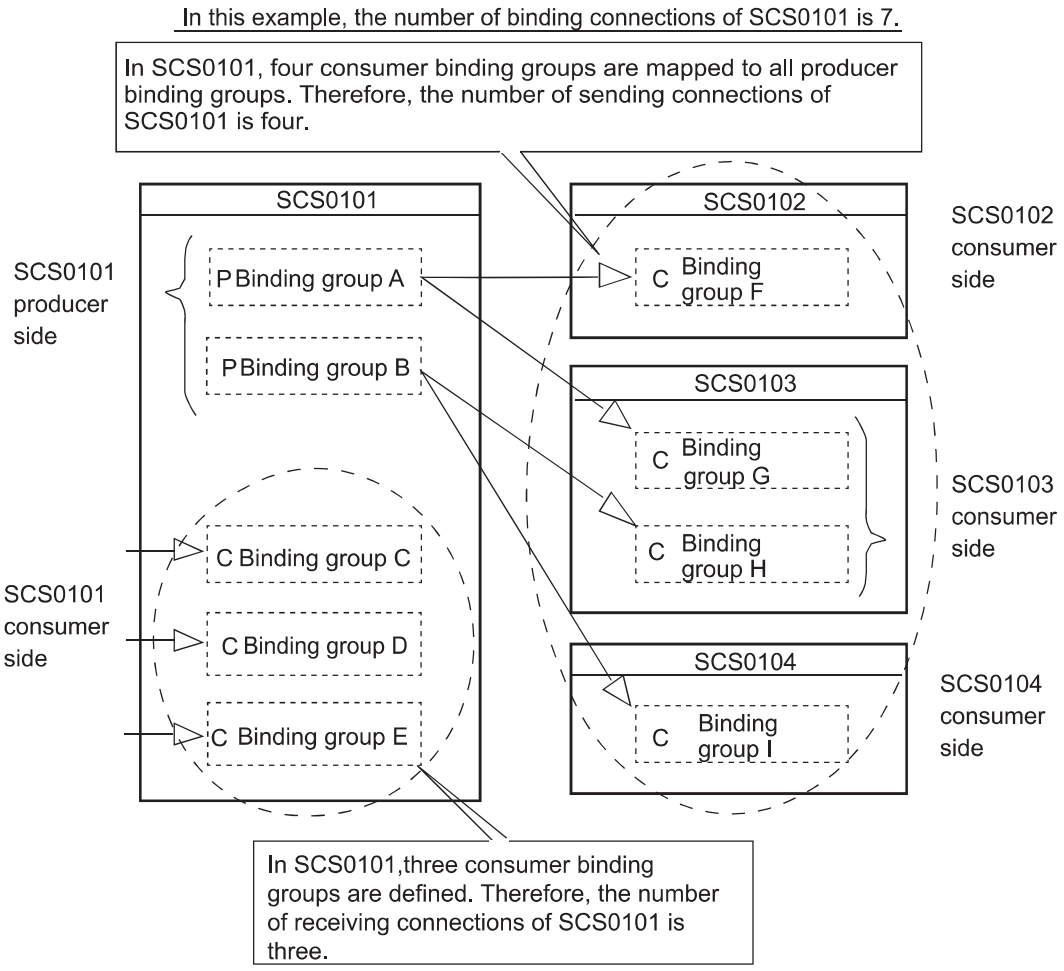

Figure A7-4 Calculating the number of binding connections

SEE ALSO For more information about range in which inter-SCS safety communication is possible, refer to:

- "● Communicable extent" on page A7-4
- Appendix 4.2, "Inter-SCS safety communication in a V net domain" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)
- "■ Inter-SCS safety communication in systems in which a V net domain and a Vnet/IP domain are connected" in Appendix 4.4, "System expansion with V net router connection" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

● Important issues to consider

- When an error occurs in Inter-SCS safety communication, a diagnostic information message is output and the fail-safe value (VAL) is set to the output of FB (OUT) for communication on the consumer. You need to design so that a proper value is set to VAL of the consumer communication FB while considering the system operations.
- The FB that is used in Inter-SCS safety communication does not have a latch function. Therefore, the value of the binding variable is output when returning from the error. You need to make the latch function in the application if necessary, in order to control the error condition and he release from the error condition by using the application.

- The above-mentioned error will be automatically recovered. A diagnostic information message is output at the recovery. The output of FB for communication on the consumer is also automatically recovered to the received data from the output value at the occurrence of an error.

IMPORTANT

- Value of a binding variable on the producer side of the Inter-SCS safety communication must not be set in two or more locations.
- Changing the binding list online causes an error at the builder.
- If you use inter-SCS safety communication, SCS projects on the consumer side and the producer side must be upgraded at the same time. If either of the SCS projects is opened by using upgraded SCS Manager, the opened SCS project is upgraded. The SCS project on the other SCS must also be upgraded by opening it with SCS Manager with the same software release number. If the revisions of the SCS projects do not match, a build error will occur.
- The software release number must be the same between all the SENGs which is for engineering SCS projects in the RS project, and SENGs which is for engineering SCSs that perform inter-SCS safety communication each other. Also, you must upgrade the revision of SCS projects that perform inter-SCS safety communication.
- Inter-SCS safety communication bindings cannot be changed online. Changing bindings (for example, adding inter-SCS safety communication or changing the SCS with which you are communicating) requires an offline download of the SCS on both the producer and consumer sides. For details, see the following “CAUTION” section.

CAUTION

- The logic for inter-SCS safety communication and the wiring of inter-SCS safety communication FB can only be changed online. For example, only the input wiring for communication FB on the producer side (see wiring A in the following figure) or the output wiring for communication FB on the consumer side (see wiring B in the following figure) can be changed. Do not make online changes for the wiring between the communication FB on the producer side and the communication FB on the consumer side. If this wiring is changed online, an error occurs in the communication FB on the consumer side, and then a fail-safe value is generated.

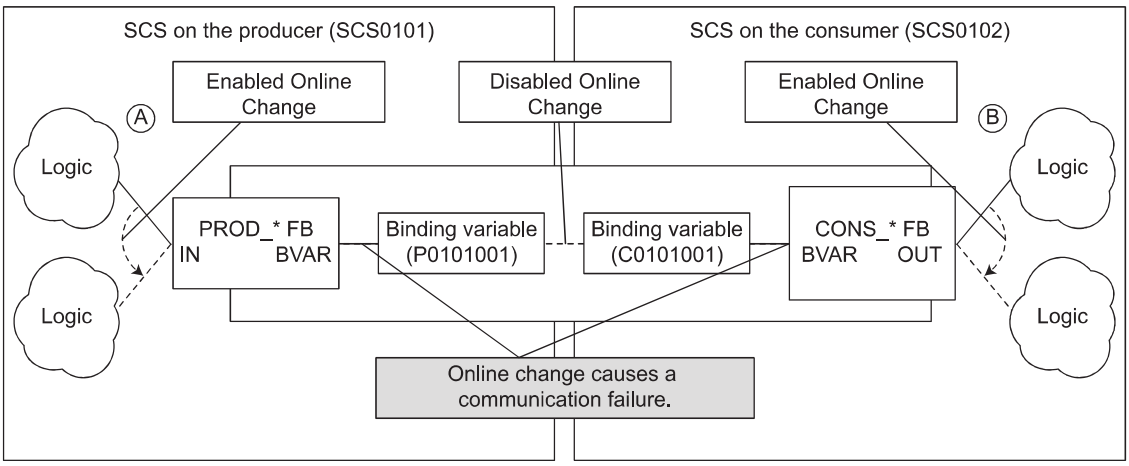

Figure A7-5 Wiring of Inter-SCS safety communication is changed online

- If the producer binding group is changed, you need to perform offline download of the group on the producer SCS as well as on every consumer SCS that references the changed binding groups. You must perform offline download irrespective of the changed contents. For example, when a variable is deleted from the binding group on the producer SCS, offline downloading is necessary on the consumer SCS even if this variable is not referenced by any consumer SCS.
- When making a wide-area connection via CGW or WAC routers, you must consider whether inter-SCS safety communication through the wide-area network is really necessary. Especially, when using a satellite connection, which is sensitive to the weather, as an inter-exchange channel, you must pay attentions because a trip may easily occur in inter-SCS safety communication. When the wide-area network does not have high performance or reliability, inter-SCS safety communication will be delayed. Then, the inter-SCS safety communication will time out due to this delay, and there will be a possible occurrence of a false trip.

  Moreover, when performing inter-SCS safety communication through WAC routers, you must set an appropriate bandwidth limit on the System View so that the inter-SCS safety communication is always given priority.
- You must use the Inter-SCS Communication Lock Window to perform lock operation on inter-SCS safety communication. If you lock the binding variables directly from the Multi-Language Editor or Dictionary, an error occurs in the consumer FBs that receive locked variables and fail-safe values are output. This may cause a false trip depending on the application.

- As a general rule, FBs for inter-SCS safety communication should be used after creating instances with names by using the Dictionary. If instance names are not assigned to inter-SCS safety communication FBs, inter-SCS safety communication is performed normally. However, the instance names that are displayed on the Inter-SCS Communication Lock Window and in system alarm messages are automatically assigned by SCS Manager.

- You must connect inter-SCS safety communication FBs and bind variables directly. If you insert any variables, function blocks, or parameters between them, forcing and monitoring cannot be performed.

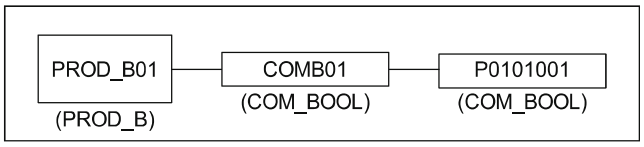

Figure A7-6 Example where FB and variable are not directly connected

- Do not use inter-SCS safety communication FBs as parameters of function blocks. If you use inter-SCS safety communication FBs as parameters, they are not displayed on the Inter-SCS Window. Also, forcing cannot be performed.

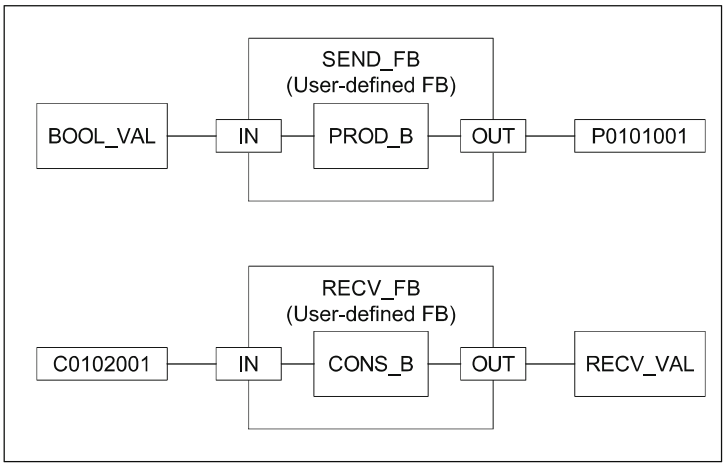

Figure A7-7 Example where Inter-SCS safety communication FBs are used as parameters

- Note that when multiple binding variables are connected to a single producer FB, if you perform forcing by selecting a line corresponding to a binding variable on the Inter-SCS Communication Lock Window, the values of all binding variables that are connected to the same producer FB will be changed. You must be careful.

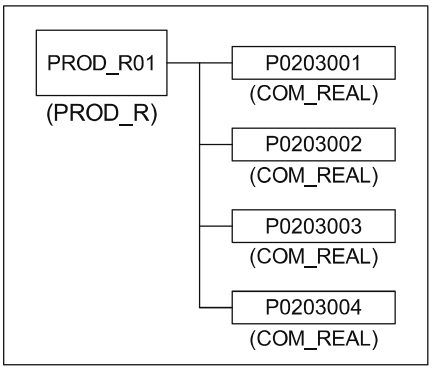

Figure A7-8 Example of multiple binding variables connected to a single producer FB

Inter-SCS Safety Communication FB — All FB

Station	L	D	Variable	Variable Type	Instance	FB Type	Logical Value	Physical Value	Variable Comment
SCS0203			P0203001	COM_REAL	PROD_R01	PROD_R	TRUE	TRUE	
			P0203002	COM_REAL	PROD_R01	PROD_R	TRUE	TRUE	
			P0203003	COM_REAL	PROD_R01	PROD_R	TRUE	TRUE	
			P0203004	COM_REAL	PROD_R01	PROD_R	TRUE	TRUE	
SCS0201			C0201001.v C0201001.sts	COM_DINT	CONS_I01	CONS_I	TRUE GOOD	TRUE GOOD	
			C0201001.v C0201001.sts	COM_DINT	CONS_I02	CONS_I	TRUE GOOD	TRUE GOOD	
			C0201001.v C0201001.sts	COM_DINT	CONS_I03	CONS_I	TRUE GOOD	TRUE GOOD	

Figure A7-9 Example of the display on the Inter-SCS Communication Lock window (multiple binding variables connected to a single FB)

- The SCS system program of the SCS that performs inter-SCS safety communication must be R1.01.30 or later on both the producer and consumer sides.

  If Vnet/IP is used for the route of the Inter-SCS safety communication, the SCS system programs on the SCSs must be R1.02 or later on both the producer and consumer sides.

SEE ALSO For more information about how to upgrade the revision of SCS project, refer to:

C4.2.2, “Upgrading an SCS project” in Installation Guide (IM 32P01C50-01EN)

For more information about DLYT (transmission delay timeout value) calculation method when the SCS system program release number of either the producer side or the consumer side of inter-SCS safety communication is R2.03.51 or earlier, refer to:

“■ Specification changes made in SCS system program (Release number R2.03.51)” in Appendix 3.2, “The major changes in R2” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Inter-SCS safety communication timeout settings

There are two timeout settings for monitoring intervals for Inter-SCS safety communication. One is the reception interval timeout value (OUTT) and the other is the transmission delay timeout value (DLYT).

A temporary “transmission delay error” is detectable by OUTT. Set DLYT to detect a constant "transmission delay error."

- Reception Interval Timeout Value (OUTT)
  Intervals to receive data are checked in the CONS_* FB for communication on the consumer. When a data reception interval exceeds the timeout value (OUTT), a communication error occurs and then a fail safe-value (VAL) is output.
- Transmission Delay Timeout Value (DLYT)
  This is the checking of the time taken between the transmission of data by producer FB(PROD_*), and the reception of the data by consumer FB(CONS_*). This time is called Inter-FB transmission delay time. When the time exceeds the timeout value (DLYT) of CONS_* and that situation continues for the time of OUTT, a communication error occurs and a fail safe value (VAL) is output.
- Setting the Reception Interval Timeout Value (OUTT)
  OUTT accepts a setting of between 3 and 30 seconds. Ensure that you set a value equal to or higher than the value obtained using the following formula. If the result of the calculation is less than 3 seconds, set OUTT to 3 seconds or more.

  In case of executing the inter-SCS safety communication through WAC routers, if the calculated OUTT is less than 10 seconds, set OUTT as 10 seconds.

  OUTT = (select the longer scan period of either the producer or the consumer) x 8 + (Additional Delay)

Table A7-2 Additional delays by network configuration

Network configuration	Additional Delay
V net	No BCV/CGW used: 0 s Via BCV/CGW: number of BCVs used x 1 s + number of pairs of CGWs used x 2 s
Vnet/IP	Within a Vnet/IP domain: 0 s Between Vnet/IP domains (no WAN): 0 s (regardless of the number of Layer 3 switches) Between Vnet/IP domains (with WAN): 1 s (regardless of the number of Layer 3 switches) Between Vnet/IP domains connected via WAC routers (with WAN): 1.3 s (*1)
If a Vnet/IP domain and a V net domain are connected	V net delay (above) + Vnet/IP delay (above) + number of V net routers x 1 s

*1: When the revisions of two SCSs for inter-SCS safety communication is earlier than R2.03.59, perform either of the following:
- Install the SNTP server for each domain connected with the WAC routers to synchronize the time.
- If the SNTP server cannot be added, add 5 seconds to the additional delay of OUTT.

- Setting the Transmission Delay Timeout Value (DLYT)
  DLYT accepts a setting of between 3 and 30 seconds. Ensure that you set a value equal to or higher than the value obtained using the following formula. If the result of the calculation is less than 3 seconds, set DLYT to 3 seconds or more.

  DLYT= (scan period of the producer) + (scan period of the consumer) + (Additional Delay)

Table A7-3 Additional delays by network configuration

Network configuration	Additional Delay
V net	No BCV/CGW used: 300 ms Via BCV/CGW: number of BCVs used x 1.3 s + number of pairs of CGWs used x 2.3 s
Vnet/IP	Within a Vnet/IP domain: 300 ms Between Vnet/IP domains (no WAN): 300 ms (regardless of the number of Layer 3 switches) Between Vnet/IP domains (with WAN): 1.3 s (regardless of the number of Layer 3 switches) Between Vnet/IP domains connected via WAC routers (with WAN): 1.3 s + Transmission delay of WAN
If a Vnet/IP domain and a V net domain are connected	V net delay (above) + Vnet/IP delay (above) + number of V net routers x 1.3 s

IMPORTANT

If DLYT is set to 0 second and the Inter-FB transmission delay check is bypassed, the received data in the corresponding inter-SCS safety communications cannot be used for the purpose of safety.

- When the result of the calculation is OUTT < DLYT, OUTT should be changed to DLYT.
- The timeout times of the Inter-SCS Safety Communication must be taken into account to calculate the system reaction time depending on the safety engineering concept.

SEE ALSO

For more information about settings for the communication timeout in inter-SCS safety communication, refer to:

6., “Function blocks for inter-SCS communication (Safety FBs)” in POU Reference Manual (IM 32P03B20-01EN)

For more information about DLYT (transmission delay timeout value) calculation method when the SCS system program release number of either the producer side or the consumer side of inter-SCS safety communication is R2.03.51 or earlier, refer to:

“■ Specification changes made in SCS system program (Release number R2.03.51)” in Appendix 3.2, “The major changes in R2” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

A7.1 Inter-SCS safety communication definition

With ProSafe-RS, it is possible to exchange data between SCSs. This section provides an overview of inter-SCS safety communication definition and engineering tasks, and explains the setting rules.

Overview of Inter-SCS safety communication definition

In order to implement inter-SCS safety communication, binding variables and inter-SCS communication function blocks are used to create application logics. BOOL-type, DINT-type and REAL-type data are grouped for each communicating SCS. Binding variables here stand for the identifiers that bind the SCS variables of sender and receiver.

The variables are defined in Dictionary View of SCS Manager.

The association among variables communicated is defined in Binding List View.

A variable that creates (sends) data is called a variable on the producing end and a variable that reads (receives) data is called a variable on the consuming end.

SEE ALSO For more information about details on Dictionary View which defines variables, refer to:

"Dictionary View" in "Workbench" in the Workbench User's Guide

For more information about details on Binding List View which links two variables between SCSs, refer to:

"External bindings" in "Variable Bindings" in "Link Architecture View" in "Workbench" in the Workbench User's Guide

Overview of engineering tasks when defining Inter-SCS safety communication

The following figure shows the overall scheme of applications for inter-SCS safety communication.

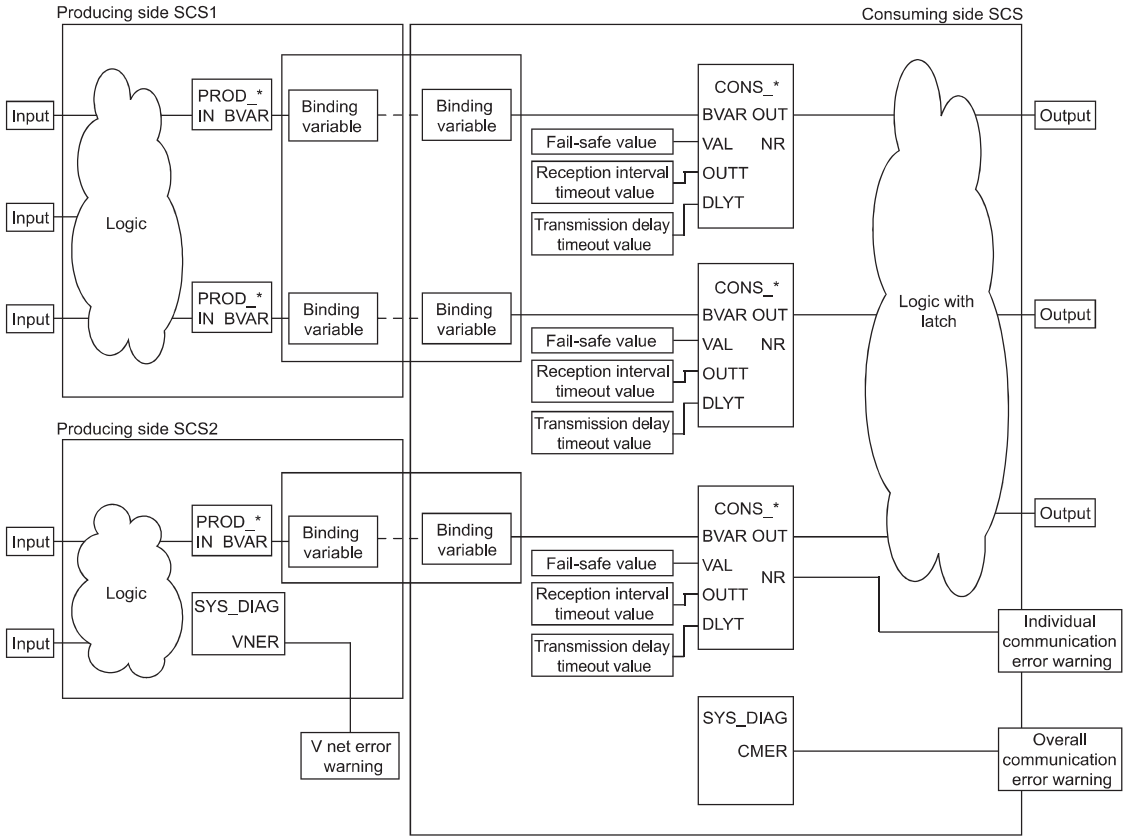

Figure A7.1-1 Overall scheme of applications

In order to communicate data between SCSs, group and define data in SCSs on the producing side and consuming side respectively. This section provides an overview of the engineering tasks.

Producing side

- Prepare an FB (PROD_B, PROD_I or PROD_R, hereinafter referred to as PROD_*) for inter-SCS safety communication for the producing side and a corresponding binding variable for each data.
- Define a global variable for the binding variable. Make sure to observe the naming rules for binding variables.
- Connect the variable to be sent with the input of the PROD_* and bind the output of the PROD_* with the binding variable.
- Make binding settings for the binding variable.
- Do not connect more than one output for PROD_* to one binding variable.
- It is recommended to describe information of the consuming side as the comment for the binding variable.
- Assign a binding group for each SCS on the consuming side.
- An error of V net communication can be output by using a SYS_DIAG. When engineering, VNER parameter of SYS_DIAG can be used for outputting the alarms.

SEE ALSO For more information about rules for naming binding variables, refer to:

"■ Binding variable" on page A7-15

Recommended guideline for engineering

For maintenance of Inter-SCS safety communication, it is recommended that the information on connection with the consume side should be written as a comment at the producer side in a program sheet.

Consuming side

- Prepare a binding variable, a corresponding FB (CONS_B, CONS_I or CONS_R, hereinafter referred to as CONS_*) for inter-SCS safety communication for the consuming side and a corresponding internal variable for each data.
- Define a global variable for the binding variable. Make sure to observe the naming rules for binding variables.
- Set a fail-safe value to be output in case the communication cannot be established or a communication error occurs and a timeout value (reception interval timeout value and transmission delay timeout value) for judging that a communication error has occurred for each data.
- Make binding settings for the binding variable.
- Assign a binding group for each SCS on the producing side.
- The communication status can be output. When engineering, NR output parameter of CONS_* for each data can be used for outputting the alarms. CMER output parameter of SYS_DIAG for the entire data can be used for outputting the alarms.

IMPORTANT

It is recommended to create a mechanism to latch requests in the logic related to inter-SCS safety communication on the consuming side.

SEE ALSO

For more information about precautions when using an SCS of an SCS system program number earlier than R2.03, refer to:

Appendix 4., “Compatibility between Revisions and Cautionary Notes for Upgrading” in Installation for ProSafe-RS R3 (IM 32Q01C50-31E)

A7.2 Combination of communication data and FBs for Inter-SCS safety communication

Use the following combinations of FBs for inter-SCS safety communications according to the type of data to be communicated.

Table A7.2-1 Combination of data types and FBs for Inter-SCS safety communication

Communicated data type	FB for inter-SCS safety communication on the producing side	FB for inter-SCS safety communication on the consuming side	Type of binding variable
BOOL-type	PROD_B	CONS_B	COM_BOOL
Integer-type (DINT)	PROD_I	CONS_I	COM_DINT
Real-number-type (REAL)	PROD_R	CONS_R	COM_REAL

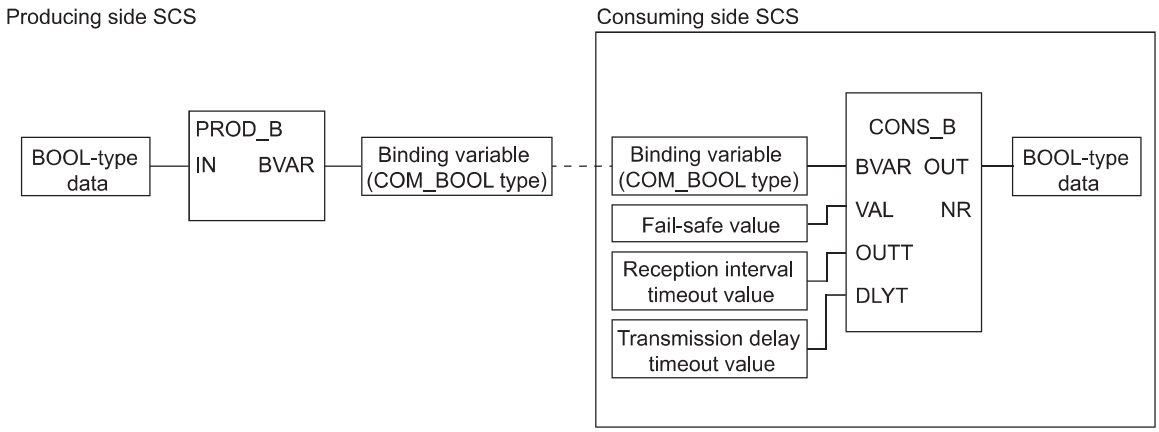

Figure A7.2-1 Combination of communication data, FBs for Inter-SCS safety communication and binding variables

In the case of an FB for inter-SCS safety communication on the consuming side, make sure to specify fail-safe value and timeout values (reception interval timeout value and transmission delay timeout value) in addition to a binding variable.

SEE ALSO For more information about details on the function blocks for inter-SCS safety communication, refer to:

6., “Function blocks for inter-SCS communication (Safety FBs)” in POU Reference Manual (IM 32P03B20-01EN)

Binding variable

There are particular rules for naming binding variables. Moreover, there are rules for binding to multiple SCSs on the consuming side for communication among SCSs.

Use the Binding List View to make settings for the binding variables.

Binding variable naming rules

- Name of binding variable on the producing side
  A character string in the form of Pddssxxx (dd represents the domain number of producing-side SCS, ss represents the station number of producing-side SCS, and xxx represents a 3-digit integer). "P" must be in upper case and "dd," "ss" and "xxx" must be 7 digits including 0, as in 0101001.
- Name of binding variable on the consuming side

The same as the binding variable name on the producing side, except that "P" is replaced with "C" (upper case).

- A "producing variable" is a binding variable starting with "P" and a "consuming variable" is a binding variable starting with "C." The numerical values for the binding variable names must be matched.

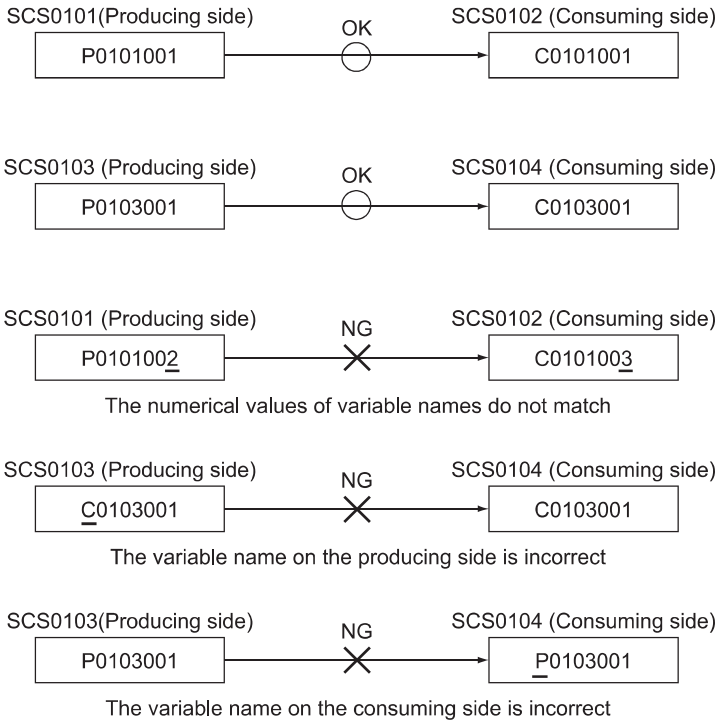

Figure A7.2-2 Binding variable naming rules

Binding rules

- It is possible to bind one binding variable on the producing side with multiple binding variables on the consuming side. In effect, this is equivalent to defining multiple 1 to 1 communications.

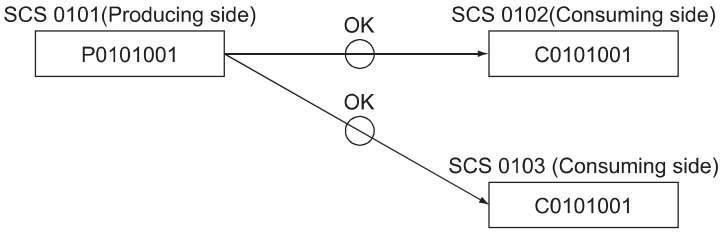

Figure A7.2-3 One binding variable on the producing side and multiple binding variables on the consuming side

- In the case of bi-directional binding, it is necessary to use different variable names. Several 1 to 1 communications are defined in this case as well.

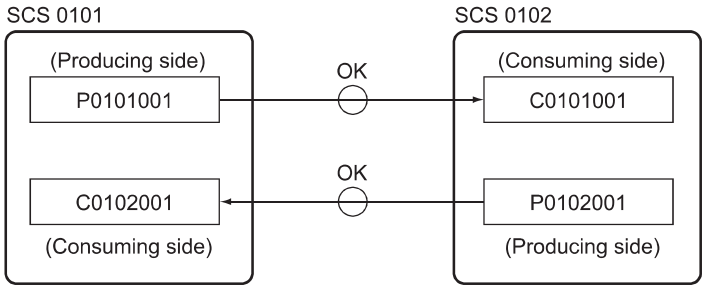

Figure A7.2-4 Use of different binding variables in bi-directional communication

Binding settings

The following items should be set for binding variables in the Binding List View.

Table A7.2-2 Binding setting items

Item	Setting Value	Remarks
Producing variable	Pddssxxx (dd: domain number, ss: station number, xxx: 3-digit integer)	The producing variable and consuming variable must have the same value of "ddssxxx."
Consuming variable	Cddssxxx (dd: domain number, ss: station number, xxx: 3-digit integer)	
Network	ETCP	Automatically set when [Producing variable] and [Consuming variable] are specified.
Communication error behavior	Use last value issued from binding	
Binding parameters	-	
Binding error variables	None	-

Setting binding groups

Create one binding group for each SCS communicating on the producing side and consuming side.

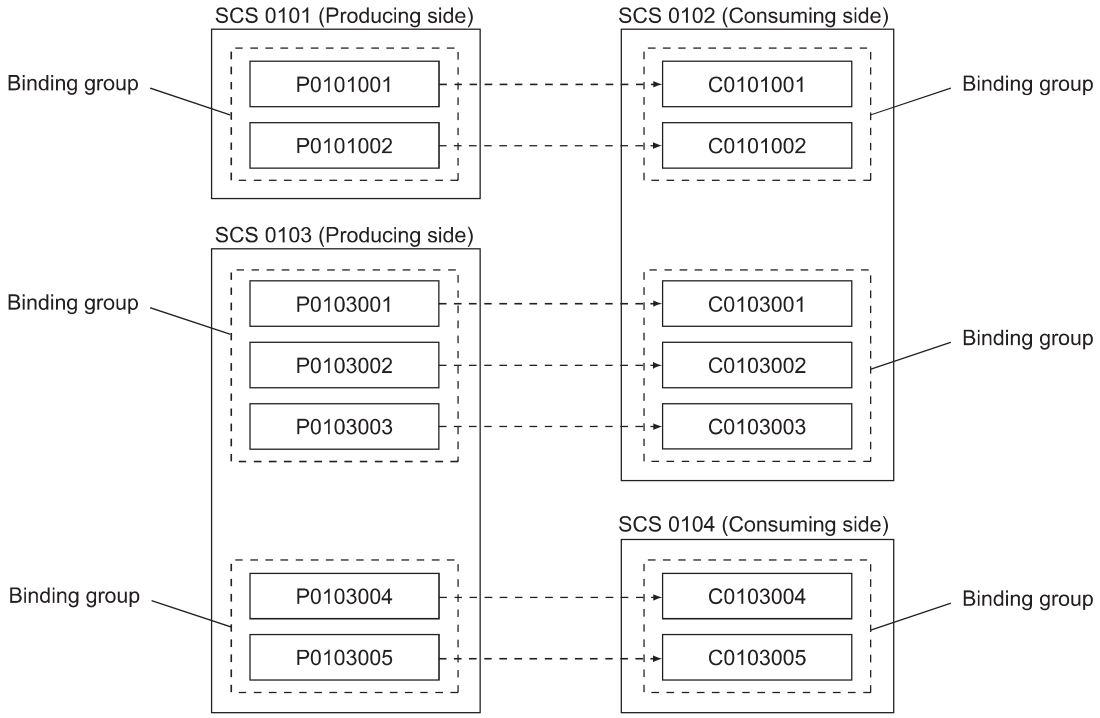

Figure A7.2-5 Binding groups

It is possible to send data from one producing side SCS to multiple consuming side SCSs. In this case, define one group on the producing side SCS for each consuming side SCS.

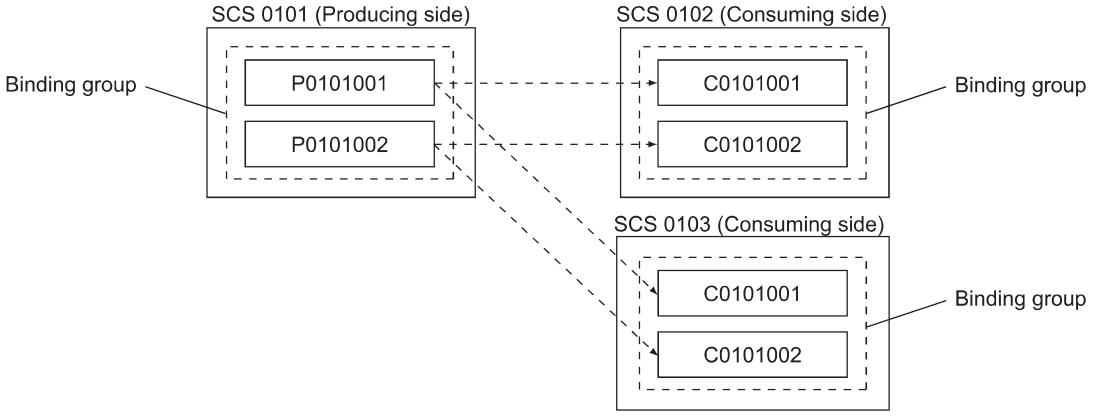

Figure A7.2-6 Relationship between one producing side SCS and multiple consuming side SCSs

When sending data between the producing side SCS and consuming side SCS bi-directionally, prepare binding variables for both the producing and consuming sides. Prepare binding groups as well for both the producing and consuming sides.

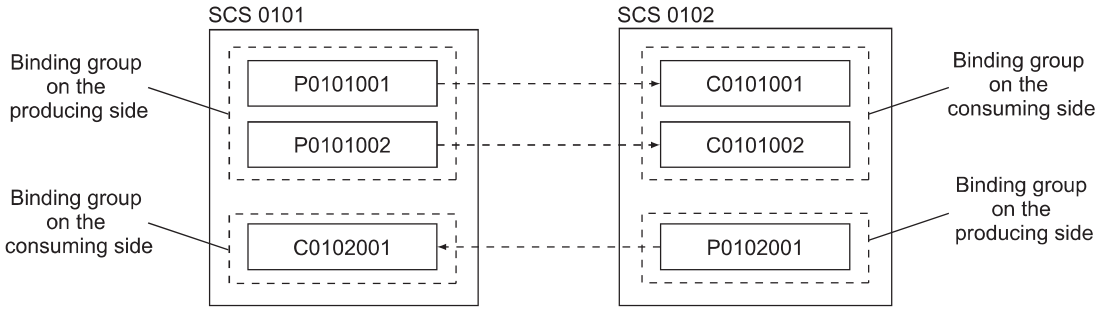

Figure A7.2-7 Bi-directional binding

SEE ALSO For more information about how to configure binding groups, refer to:

"External bindings" in "Variable Bindings" in "Link Architecture View" in "Workbench" in the Workbench User's Guide

A8. SOER functions and how to use them

This section describes functions of the SOER.

The SOER (Sequence of Events Recorder) is for recording and analyzing events detected by SCS. In ProSafe-RS, the SOER is used for the user to analyze the cause of a trip based on the event information detected right before and after the trip.

The user provides definition related to the SOER on SENG. The definition is downloaded to the CPU and the DI module of SCS. The event collected and saved by SCS is uploaded to the SOE viewer on SENG or HIS.

SEE ALSO

For more information about engineering for SOER, refer to:

A8.5, “SOER collection definition” on page A8-12

For more information about host interface, refer to:

C1., “Overview of SOE OPC Interface” on page C1-1

For more information about SOE viewer, refer to:

I4.3, “SOE Viewer” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

A8.1 Overview of SOER

With a SOER, changes in analog inputs/outputs, discrete inputs/outputs and application logics can be collected/saved as event information. Collected event information is displayed in the SOE Viewer. Moreover, a function to synchronize to the standard time is provided in order to maintain the accuracy of the time stamps attached to the events.

ProSafe-RS SOER

Configuration

The SOER function of ProSafe-RS can be used for a minimum system configuration, i.e., one SENG and one SCS.

Event collection

- The SOER function of ProSafe-RS can collect changes of not only discrete inputs (DI) but also discrete outputs (DO) as event information.
- Analog input values can also be collected as event information.
- By creating FBs for SOER, changes of analog output values and application logics can be collected as event information. By doing so, changes of communication data with other SCSs can also be recorded.

Event saving

- You do not need to prepare a dedicated PC for saving events or keep the power supply to an SENG on at all times, because event information is saved in the SCS.
- The maximum number of event information records that can be saved in an SCS is 15000. You can be sure that users are successfully notified of particularly important event information, i.e., records acquired before and after a trip signal was generated, by separating the storage location.

SOE Viewer

- Event information saved in an SCS can be read by the SOE Viewer function in an SENG via the control bus.
- SOE Viewer allows filtering the event information so that only the information the user wants to see is shown.
- SOE Viewer can display diagnostic information messages as well.

Relationship among the SOER functions

The following figure illustrates a structure of functions related to SOER.

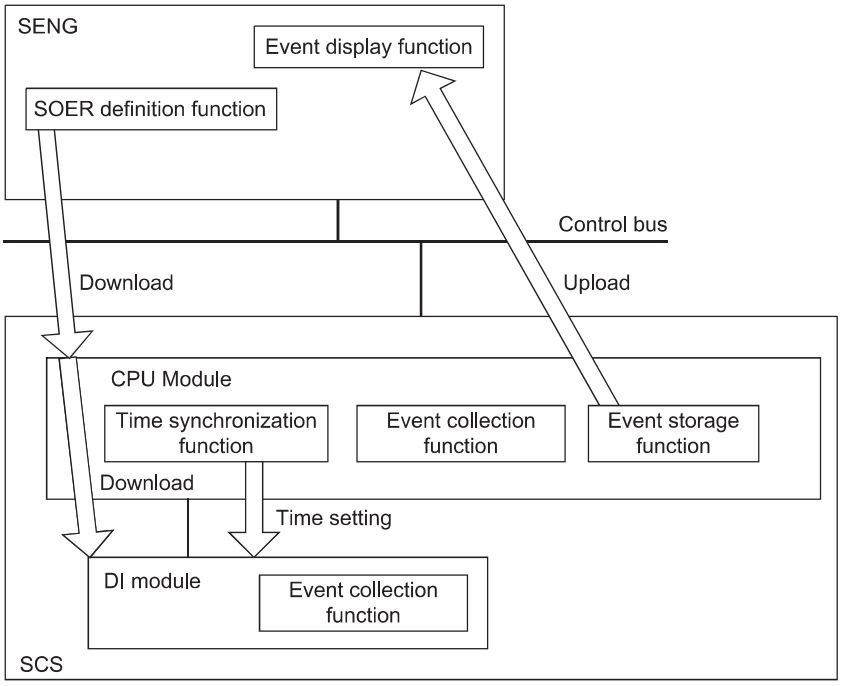

Figure A8.1-1 Relationship between SCS and SENG

The user defines items related to SOER on an SENG. The defined information is downloaded to the CPU of an SCS as well as to discrete input modules in the system. The event information collected/saved in the SCS is uploaded to SOE Viewer in the SENG or HIS.

With SCSs connected to the V net, IRIG-B time synchronization can be selected.

With SCSs connected to the Vnet/IP, time synchronization is implemented based on the Vnet/IP time.

A8.2 Event collection

An SCS allows saving specified discrete inputs, discrete outputs, analog I/O, and variable data of application logics as event information.

Event targets

An SCS can save the following data as event information by user specification.

Events related to discrete inputs (DI) are collected by the input modules; other events are collected by the CPU.

Events of discrete inputs (DI)

- Discrete input modules detect changes in the input signals input to each channel (FALSE to TRUE or TRUE to FALSE) and collect events.
- Users can specify whether or not to collect SOE event information for each channel.
- If discrete input modules are placed in redundant configuration, the active module collects events.
- The comment text attached to the variable corresponding to each DI channel is added to the event. The text can contain a character string of up to 32 single-byte characters, or 16 double-byte characters. The user needs to define the variables corresponding to the contact inputs on the Workbench Dictionary View as the comments so as to identify the whereabouts of the occurred events.

Events of discrete outputs (DO)

- The CPU detects changes in the output value set to a discrete output module and collects events.
- Users can specify whether or not to collect SOE event information for each channel.
- If the output channel is abnormal (data status is BAD), the events will not be gathered.
- Each event is attached with a comment text assigned as a variable to the contact output (a character string of up to 32 single-byte characters or 16 double-byte characters). The user needs to define the variables corresponding to the contact outputs on the Workbench Dictionary View as the comments so as to identify the events.

Events of analog inputs (AI)

- The ANLG_S function block outputs alarms by judging analog input values, and it is able to collect events by making appropriate application. It performs magnitude correlation comparison of set values and analog output values (OUT) and collects events by using a change in OUT as a trigger.
- Events are collected when the SOER input terminal is set to TRUE.
- At event collection, a character string set to the ID input (a character string of up to 32 single-byte characters or 16 double-byte characters) is stored along with the event data.

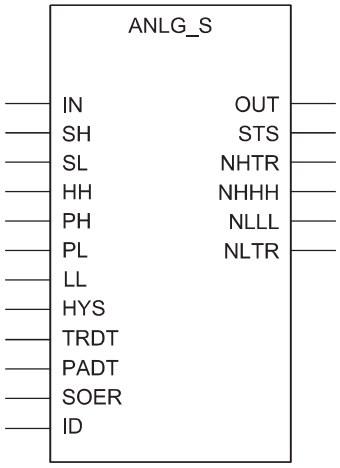

Figure A8.2-1 ANLG_S function block

An ANLG_S function block collects events when the following outputs change their status from FALSE to TRUE, or from TRUE to FALSE:

- NHTR (HI trip flag)
- NHHH (HI pre-alarm flag)
- NLLL (LO pre-alarm flag)
- NLTR (LO trip flag)

When the event occurred can be checked in the ID field of the SOE Viewer.

Table A8.2-1 ANLG_S event IDs

ID in SOE Viewer	Event generation timing
EVT_TRUE	When an alarm recovered (when output status change from FALSE to TRUE).
EVT_FALSE	When an alarm generated (when output status change from TRUE to FALSE).

Events of application logic variables

An SCS collects values of internal variables defined in an application logic as events by connecting them to function blocks dedicated to the SOER function. Variables of the BOOL, integer or real number types can be collected. At event collection, a character string specified in the ID input (a character string of up to 32 single-byte characters) is stored along with the event data.

Use SOE_R to collect analog output events. In IN, enter an output variable. In TRIG, enter a signal that specifies the event collection timing.

The following function blocks are dedicated to the SOER function. Note that events from function blocks are treated as trip signals if TRIP_OFF or TRIP_ON is specified for TRP.

- SOE_B (BOOL type) function block
  SOE_B is a function block used to collect BOOL-type data as events. It collects events if there is a difference between the input value (IN) and the previous value at the execution timing of the function block. The default value of the previous value is 0.

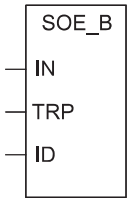

Figure A8.2-2 SOE_B function block

- SOE_I (integer type) function block
  SOE_I is a function block used to collect integer-type data as events. It collects events if the value of TRIG, an input terminal, changes at the execution timing of the function block.

Figure A8.2-3 SOE_I function block

- SOE_R (real number type) function block
  SOE_R is a function block used to collect real number-type data as events. It collects events if the value of TRIG, an input terminal, changes at the execution timing of the function block.

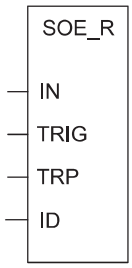

Figure A8.2-4 SOE_R function block

When the event occurred can be checked in the ID field of the SOE Viewer.

Table A8.2-2 Event IDs of dedicated SOE function blocks

FB type	ID in SOE Viewer	Event generation timing
SOE_B	EVT_TRUE	When the status of IN input changed from FALSE to TRUE.
	EVT_FALSE	When the status of IN input changed from TRUE to FALSE.
SOE_I SOE_R	EVT_TRUE	When the status of TRIG input changed from FALSE to TRUE.
	EVT_FALSE	When the status of TRIG input changed from TRUE to FALSE.

Event time

Event information records include a time stamp indicating when the event occurred. The event generation time varies depending on the event type (object).

Table A8.2-3 Event time

Object	Time information of event
Discrete input (DI)	The current time of a discrete input (DI) module at event generation is recorded.
Discrete output (DO)	The current SCS time is stamped to the signal right before outputting it through the output module.
Variable	The current time of the SCS right before the execution timing of a function block is recorded.

Recording of occurrence times of DI module-related events

After an occurrence of channel failure, such as open or short circuit, if you check the SOE Viewer to view a diagnostic information message, you will find that the channel error is displayed after the ON/OFF event of the applicable channel. This means that the time of event occurrence does not match the time of the message. This is because the event and the message are generated by different modules: the DI module generates events and the CPU module generates diagnostic information messages.

When an event occurs, event information is generated based on the DI module time at the occurrence. On the other hand, diagnostic information messages for channel errors, etc., are generated during I/O refresh processing of the CPU module based on the error information received from the DI module, in accordance with the time information acquired at the start of each scan period.

A8.3 Event storage

Event information is stored in the SOER event information storage memory of an SCS. There are two types of files in which event information can be stored: an event log file and trip signal files. An event log file stores the latest event information. In the trip signal file, events before and after each trip signal are saved.

Saving event data

- An SCS saves event data using two types of files: an event log file, which stores event information in the order of data collection, and trip signal files, which store events generated before and after the trip signal specified by the user. There are two trip signal files.
- Event information saved in an SCS is not deleted when read by an SENG and HIS. It is thus possible to reference the information from multiple SOE Viewers.

Flow of event storage

The figure below illustrates the flow according to which event information is stored in an SCS.

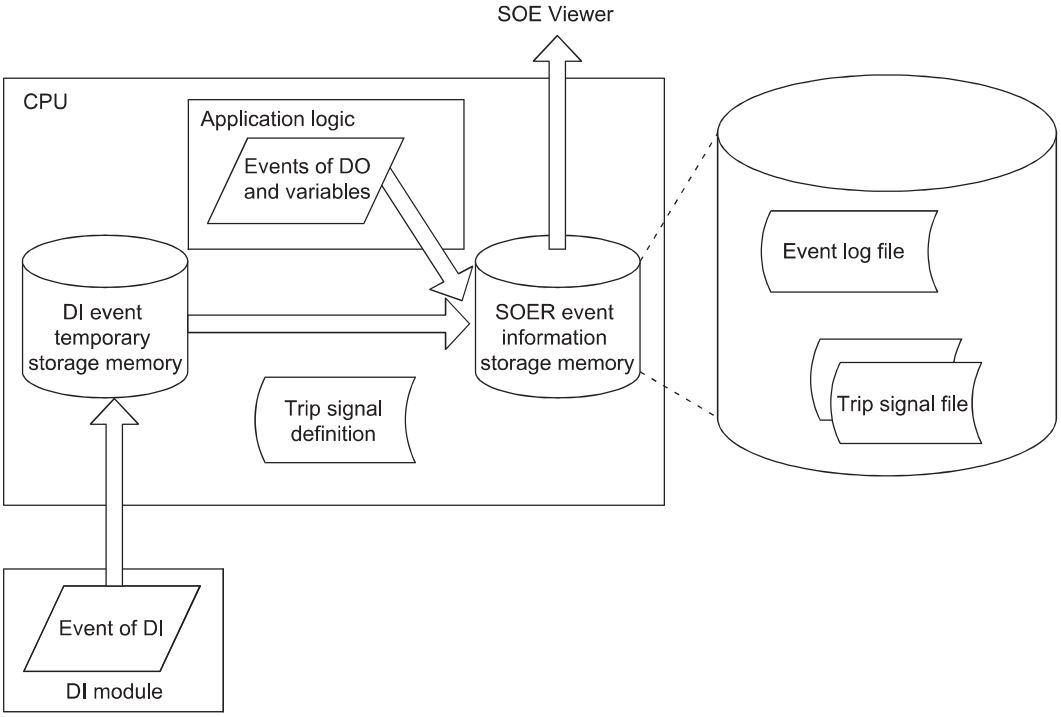

Figure A8.3-1 Flow of data in event information storage

Since event information from a discrete input (DI) module is automatically stored in the DI event temporary storage memory of the CPU, both the DI event in this memory and event information collected in the application logic are stored in the SOER event information storage memory.

Specification of event log files

- An event log file stores the latest event information and one event log file is saved per SCS.
- Up to 15,000 events can be saved in the event log file.
- If the number of events saved exceeds the maximum number, events are deleted and overwritten by new events from the oldest one.

- Whenever an SCS has saved 12,000 events in the event log file, it sends a diagnostic information message to prompt the user to upload to the SENG.

Trip signal

- Trip signals are particularly important events in the plant. Since they are key events when engineers attempt to analyze the causes of tripping, they must be securely stored in the SCS together with the events generated before and after them.
- Either ON edge or OFF edge can be specified as the trip signal. However, both edges can be specified as ignored.
- Users can specify trip signals in input/output definitions or in function blocks for SOE. There is no restriction on the number of trip signals that can be specified, but it is necessary to examine trip signal settings thoroughly in order to record useful event information.

Specification of trip signal files

Trip signal files store events generated before and after a trip signal specified by the user.

- An SCS stores events generated before and after the trip signal in a trip signal file.
- A trip signal file stores 1500 events in total: the last 500 events generated before tripping including the trip signal and the 1000 events generated after tripping.
- Up to two trip signal files can be stored in the SCS. Even when more trip signals occur, no more trip signal file is created. If a trip signal file is created, you need to upload and initialize the trip signal file from SENG immediately.
- Trip signal files are not automatically initialized by the system. The files can be initialized only through operation from SENG.
- If two trips occur in a short period of time, the data in the two trip signal files may overlap.
- If less than 500 events are collected prior to a trip event, the number of the events before the trip event is less than 500.
- If the number of events is less than 1000 after 30 minutes has passed since the trip event occurred, the file will be closed anyway with less events.
- An SCS sends a diagnostic information message when saving of a trip signal file is completed.

SEE ALSO For more information about initializing the trip signal file, refer to:

I4.2.5, “Initialization of tripping information” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Initialization of trip signal files

Trip signal files can be initialized only via initialization operation from the SENG. After you have uploaded events from the SOE Viewer on the SENG, initialize the trip signal files using the Message Cache Tool of the SENG.

- Up to two trip signal files can be initialized with a single operation.
- Initialization operation is also valid while events are being stored.

A8.4 Management of event information when SCS is unsteady

This section explains the management of event information in the following cases of unsteadiness.

- A power failure occurs in the SCS
- During startup of the SCS
- I/O variables are locked

If a power failure occurs in an SCS, event information is saved in NVRAM (nonvolatile RAM). The SCS restores the event information at startup; it is thus possible to check the event information before the SCS was stopped.

Protection of event information at power failure

Generally, event information is stored in the main memory of an SCS. If a power failure occurs in the CPU, the data saved in the main memory is lost. Therefore, the SCS saves the most recent events recorded immediately before the power failure to NVRAM (nonvolatile RAM). Although not all of the events can be protected, it is possible to analyze events that occurred immediately before the power failure by protecting them in this way.

Table A8.4-1 Protection of event information at power failure

File type	Specifications at power failure occurrence (*1)
Event log file	The most recent 1000 events recorded immediately before the power failure are protected.
Trip signal file	Upon completion of collection, the trip signal files are saved to NVRAM (nonvolatile RAM) (up to 1500 events x 2 files). If the files have been fully saved prior to the power failure, all events are safe. If the power failure occurred before the files are fully saved, the events are lost. (*2)

*1: The same operations apply to offline download.
*2: If the most recent events are not saved, refer to the event log file.

SCS startup operation

An SCS restores the event information that was saved before it was stopped when it starts up at restarting or after offline download.

Lock status by the forcing function

If I/O variables are locked by the forcing function, event collection is performed in the following ways when the values of the I/O variables change.

Table A8.4-2 Event collection operation in the locked status

Object	Event collection operation
Discrete input (DI)	Since events are collected by a discrete input module, events are collected based on the actual values input to the module regardless of the lock status. Events are not collected if the value of the discrete input is changed by the forcing function.
Discrete output (DO) (*1) Analog input (AI)	Since events are collected by an application logic, events are collected with the changed value if the values of I/O variables are changed by the forcing function.

*1: In order to collect events, it is necessary that the DO modules are operating normally and the data status of the output channels are GOOD.

SEE ALSO For more information about SOE event collection when switching module control rights, refer to:

A8.6.1, “Redundant configuration in SCS” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

A8.5 SOER collection definition

The SOER collection definition defines which events to collect.

By using SOE Viewer, it is possible to analyze collected events and save them in files. This section explains the types of targets for which events can be collected.

SEE ALSO For more information about SOE viewer details, refer to:

I4.3, “SOE Viewer” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Definition of event collection objects

The setting method of event collection definition varies depending on the object. Events can be collected either from a discrete AIO/DIO module or an application logic.

Objects of event collection

The following types of events can be collected for SCSs.

- Signal changes of discrete input modules
  It is possible to collect events from discrete input modules according to the changes of data input from individual channels. Specify whether or not to collect events for each channel.
- Signal changes of discrete output data
  It is possible to collect events according to the changes of data output to individual discrete output channels. Specify whether or not to collect events for each channel.
- Alarms on Analog input data and Recovery
  It is possible to collect events by comparing the output values with the settings of alarm level set to the analog input block.
- Variation of Analog output data
  It is possible to collect events based on the variation of output variable. Take the settings of the output variable into SOE_R, and specify the conditions of event generation.
- Changes of internal variable of an application logic
  It is possible to collect events according to the changes of an internal variable of an application logic. Specify the object internal variable and conditions of event generation.

Event collection definition for Discrete Input/Output modules

For each channel of a discrete input/output module, you can specify whether to perform SOER collection by setting an I/O parameter. Events are collected when the channel signal of the discrete input/output module changes.

SEE ALSO For more information about I/O parameter setting items for modules, refer to:

Appendix 1.2, “Settings for modules” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about I/O parameter setting items for channels, refer to:

Appendix 1.3, “Settings for channel items” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Event collection definition for application logic

Events generated at input from an analog input and signal change in an application logic can be collected. To collect events, add a function block that can collect events in a program or a function block. There are the following four types of function blocks that can collect events according to the target data type.

Table A8.5-1 Function Blocks that can collect data

Data type	Function block	Description
BOOL	SOE_B	Records BOOL-type data values as events when a specified trigger value changes
DINT	SOE_I	Records DINT-type data values as events when a specified trigger value changes
REAL	SOE_R	Records REAL-type data values as events when a specified trigger value changes
IO_REAL	ANLG_S	Used for SOER on analog input. If an alarm is raised as the result of a data value exceeding the limit and the status continues for a specified period of time, the alarm status is recorded.
	ANLGI	Used for SOER on analog input. Records data values as events when the data value gets outside the specified range.
	HSDTR	Records IO_REAL-type data values as events when an alarm occurs and upon recovery.
	GASDTR	

TIP

It is necessary to append a character string to the ID terminal of a function block in order to identify events. The character string must be up to 32 characters.

SEE ALSO

For more information about details on the function blocks of SOE, refer to:

8., “Interference-free function blocks” in POU Reference Manual (IM 32P03B20-01EN)

For more information about details on the analog input function blocks with data status, refer to:

5.7, “ANLG_S (analog input function block with data status)” in POU Reference Manual (IM 32P03B20-01EN)

For more information about details on the analog input function blocks, refer to:

5.8, “ANLGI (analog input)” in POU Reference Manual (IM 32P03B20-01EN)

Event collection of application logic

The following figure shows an example of an application with FBs for the SOE event collection.

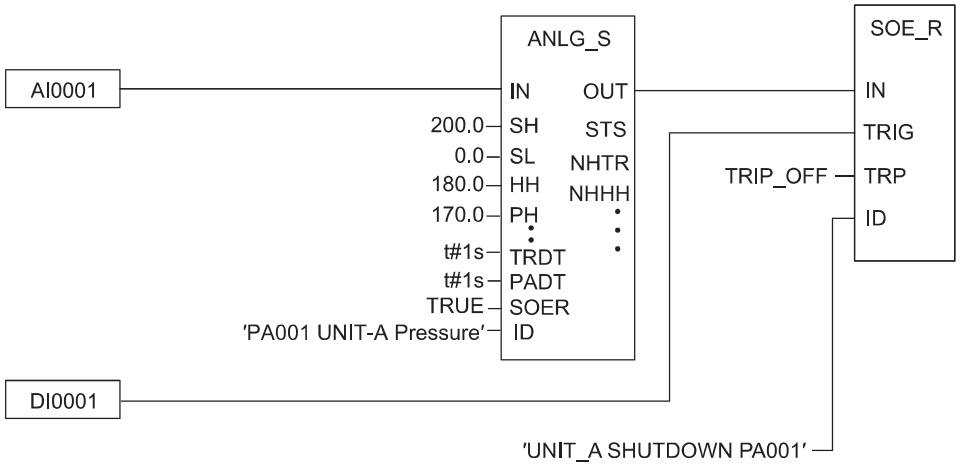

Figure A8.5-1 Example of application with FBs for SOE event collection

In the figure, the "SOE_R" FB collects the output value (OUT) of the "ANLG_S" FB together with the character string "UNIT_A SHUTDOWN PA001" when DI0001 changes value. The SOER of the "ANLG_S" is set to TRUE, so that the "ANLG_S" FB collects the alarm status with the character string "PA001 UNIT-A Pressure" when alarm of the FB occurs.

Precautions for creating an application

- Comment(s) is added to the DI events and DO events. Comments are bound with I/O variables wired to its channel. (Max. 32 characters) The user should set character strings that can identify events for the I/O variables.
- For the function block (ANLG_S/ANLGI/SOE_*) used for acquiring events on variables in application logic, specify the number of characters (max. 32 characters) for comments added to events. Comments are used to identify events.
- For acquiring analog output value (AO) as events, specify the 'value set to output variable' in SOE_R also. Specify the timing of acquiring events as a trigger signal in application.

A9. HART communication

Analog I/O module with HART communication (hereinafter called HART modules) on ProSafe-RS allows Plant Resource Manager (PRM) to control the HART communication devices connected to input and output on SCS. Also, HART modules allow PRM to conduct Partial Stroke Test (hereinafter called PST) on HART-supported valve positioner equipped with the PST function.

The HART modules on ProSafe-RS are interference-free and have no impact on the safety functions on SCS.

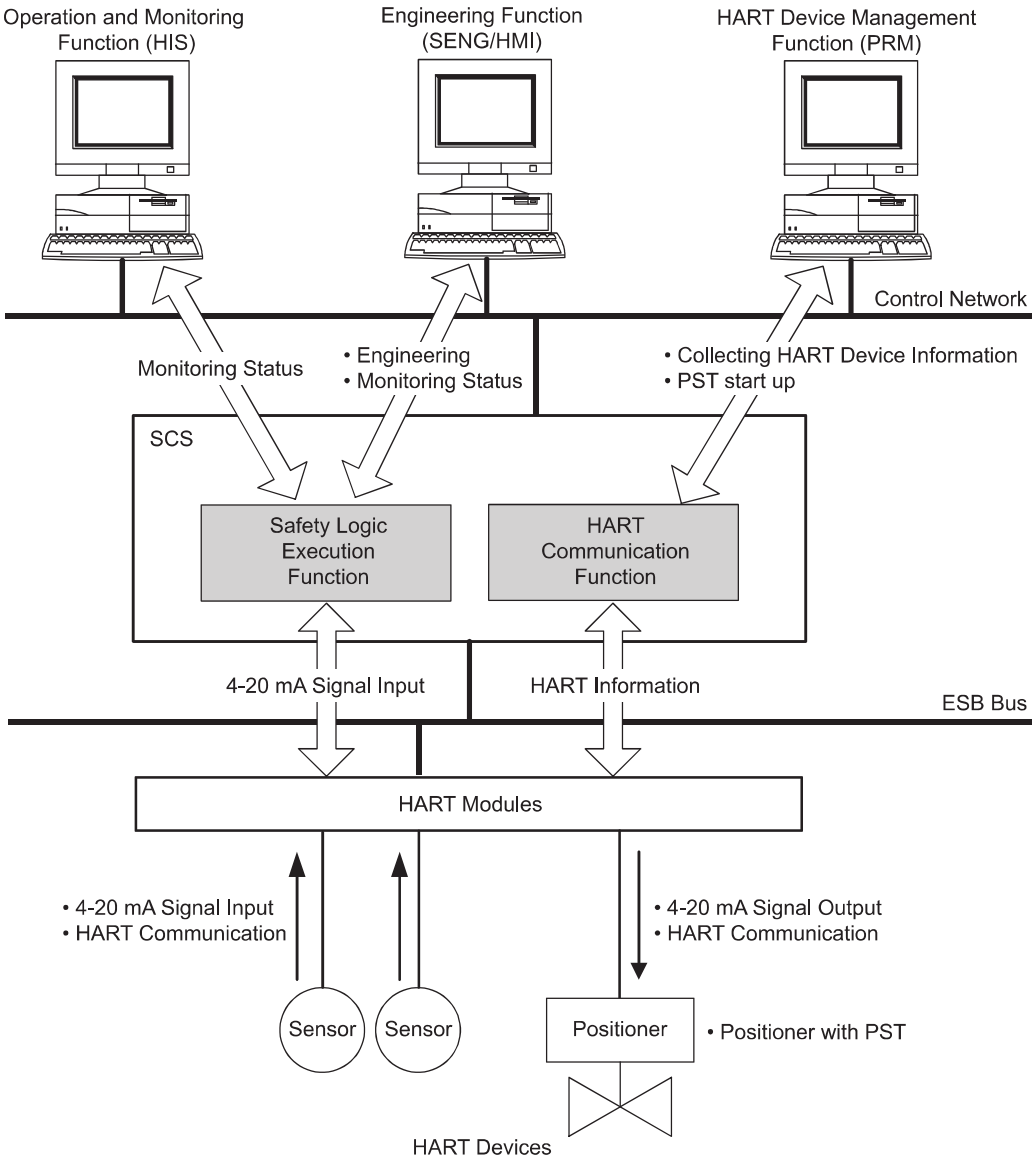

Figure A9-1 HART Communication function

A9.1 Description

This section introduces input and output modules supporting HART communication functions and provides precautions to perform HART communications.

AI/AO modules for HART Communication function

The following table shows the AI/AO modules for HART communication available to ProSafe-RS.

Table A9.1-1 AI/AO modules for HART Communication function

Module	Model	Description	Remark
Analog input module (Current input)	SAI143-H/ L1AI143-H	16 channel; 4 to 20 mA, Isolated	HART communication function
Analog output module (Current output)	SAI533-H/ L1AI533-H	8 channel; 4 to 20 mA, Isolated	HART communication function
Analog digital I/O module	S2MMM843	AI/AO/DI/DO 16 channel, module isolation	

One HART device is connectable for each channel of these modules. Each channel is equipped with a power supply function to the HART device.

As analog input modules and analog output modules have only one HART modem for each module, only one HART device can communicate at a time through a single module.

For the analog digital I/O module, one HART device can be connected to each channel. As the analog digital I/O module has one HART modem for each channel, multiple HART devices can communicate at a time through a single module. For one analog digital I/O module, a maximum of 16 HART devices for AI or 8 for AO can be connected.

SEE ALSO For more information about HART communication function specific to N-IO, refer to:

A9.3, “HART communication function specific to N-IO” on page A9-6

ProSafe-RS software setting items

Among the valve positioners equipped with the HART communication function, there are types capable of HART communication even during the output of a shutdown (valve fully closed) (*1). If you set the Shutdown output value for the analog output module on ProSafe-RS in accordance with the specifications of the valve positioner, HART communications continue even after the valve is shutdown. To do so, set the following parameters for the analog output module on ProSafe-RS based on the specifications of the valve positioner.

- Shutdown output value
- Tight-shut output value
- Output value at fault

*1: For example, specifications of some HART-supported valve positioners are defined as: 14 mA or more: Full open; 5.6 mA or less: Full close; 3.8 mA or more: HART communications allowed. In this case, set 'Shutdown output value', 'Tight-shut output value', and 'Output Value at Fault' to 3.8 mA (within the range where HART communications are allowed and safety shutdown is guaranteed), and HART communications continue even after the valve is full-closed.

Precautions for using HART devices

There are certain precautions to be taken regarding any HART devices that you are using and to be observed during their use.

Precautions regarding HART devices

If HART devices (such as sensors, multiplexers, positioners, and handy terminals) are used in Safety loop, the devices must meet the requirements for the Safety loop (such as SIL certified: Self-diagnosable for HART circuit failure and capable of notifying it to external devices).

A failure in HART devices may affect field signals and cause errors such as false trip or no demand responding. If HART devices are incapable of notifying the errors, ProSafe-RS has no way to recognize them.

You must use devices not-constantly connected to the system such as a handy terminal only when the plant is shutdown or when maintenance work is being performed while no hazardous situation is created even if field signals are affected. If you have to use a handy terminal while the plant is in operation, make sure that the handy terminal works correctly and take the above mentioned risks into account.

Dealing with HART communication errors

If an error occurs in communication via a HART module between a HART communication device and PRM and there is nothing wrong in the communication route between the HART communication device and the HART module, the HART circuit inside the HART module may have failed. When an error occurs in the HART circuit, the control rights for the module are not switched, even if the HART module has a redundant configuration. In such cases, use the IOM Control Right Switching Tool to switch the control rights for the module and check whether communication is restored. If communication returns to normal as a result of switching the control rights, it is possible that the problem was caused by a HART circuit failure in the module on standby. In this case, ensure that the module is replaced.

SEE ALSO For more information about IOM Control Right Switching Tool, refer to:

I4.7, “IOM Control Right Switching Tool” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

A9.2 PST engineering

From a PC integrated with PRM in which PST supported Plugin Software (hereinafter called Plugin for PST) is installed, you can execute PST on the valve positioner that supports the Plugin. Operations for and configuration of the PST are performed from the Plugin for PST. Plugin for PST communicates with the valve positioner via HART communications protocol. The valve positioner executes PST based on the information from the Plugin for PST and stores the test results inside. You can refer to the stored result by Plugin for PST, so you can determine the status of the valve (normal/abnormal) based on the result.

To build such a PST environment, consideration must be given to the following:

- PRM Configuration
- PST Engineering

PRM Configuration

PRM configuration includes:

- Register devices connected to ProSafe-RS in PRM.
- Register the 'Plugin for PST' software in PRM.
- Set the handling manner of errors raised by ProSafe-RS (such as system or device alarms) (*1)
- Customize to distinguish SIS devices from DCS devices.

All engineering work for PRM is done on PRM. For details, see User's Manuals for PRM.

*1: Error handling here means setting parameters for PRM's Fault Notification functions (such as Device Patrol and Maintenance Alarms). PRM is an interference-free product including its error handling functions.

PST engineering

PST engineering includes the following parameter settings:

- Interval of PSTs
- Valve close level in PST (Percentage)
- Criteria for raising errors
- How to activate PST (Manual or Auto)
- If PST is automatically activated, how to notify errors (*1)

*1: If PST is automatically activated, available error notification methods are: sending alarms to HIS via PRM or using the output contacts equipped with the valve positioner. For the specifications of the output contacts on the valve positioner, see its specifications.

All the PST engineering work is done from Plugin for PST or Valve positioner. For details of the engineering work, see the User's Manuals for the Valve positioner.

Some Plugin for PST are capable of working in conjunction with PRM client. For details, see the User's Manuals for Plugin for PST.

Safety Integrity Level (SIL)-certified and PST-supported valve positioner is provided with a manual which describes precautions for conducting PSTs. Be sure to read the manual and follow the given procedures for conducting PSTs.

Precautions for building PST environment

The following must be observed when PST environment is built:

- Specifications of the valve positioner define that the shutdown output from ProSafe-RS has the highest priority (even in a PST).

- When an online change download is implemented with the configuration of the analog output module, the entirety of the analog digital I/O module, or the AO channel of the analog digital I/O module, ProSafe-RS is temporarily disconnected from HART communications. For this reason, do not perform online change download for said modules while using the Plugin for PST software (in other words, while conducting HART communication). If an online change download is performed and a HART communication error occurs, retry the operation of the Plugin for PST after recovery of the module.
- According to the manual for the valve positioner, setup the ProSafe-RS.

A9.3 HART communication function specific to N-IO

This section describes the HART communication function that is specific to N-IO.

I/O module for the HART communication function of N-IO

The following table shows I/O modules that are available in ProSafe-RS for N-IO for the HART communication function.

Table A9.3-1 I/O module for the HART communication function of N-IO

Module	Model	Basic functions	Remarks
Analog digital I/O module (16 channel, module isolation)	S2MMM843	16 channel, module isolation AI/AO: 4 to 20 mA DI/DO: 24 VDC	• Only AI/AO supports HART communication function • You can switch among AI/AO/DI/DO in each channel

The Analog digital I/O module can use a different signal category (AI/AO/DI/DO) for each channel. For the signal category is AI or AO, one HART device can be connected to one channel with a signal type of a current input (HART communication) or current output (HART communication). Each analog channel is equipped with a power supply function to the transmitter.

As the analog digital I/O module has one HART modem for each channel, multiple HART devices can communicate at a time through a single module. For one analog digital I/O module, a maximum of 16 HART devices for AI or 8 for AO can be connected.

A9.3.1 Status change notification function of HART devices

You can use the status change notification function of HART devices when using N-IO in SCSP3 of CENTUM integration environment. The functions are interference-free and have no impact on the safety functions on the SCS.

These functions are divided into two features: a function for detecting the change of status of a HART device (device status change detection function) and a function for notifying PRM of the detected information through HIS (device status change notification function).

The following figure shows the concept of the notification of the status change in HART devices.

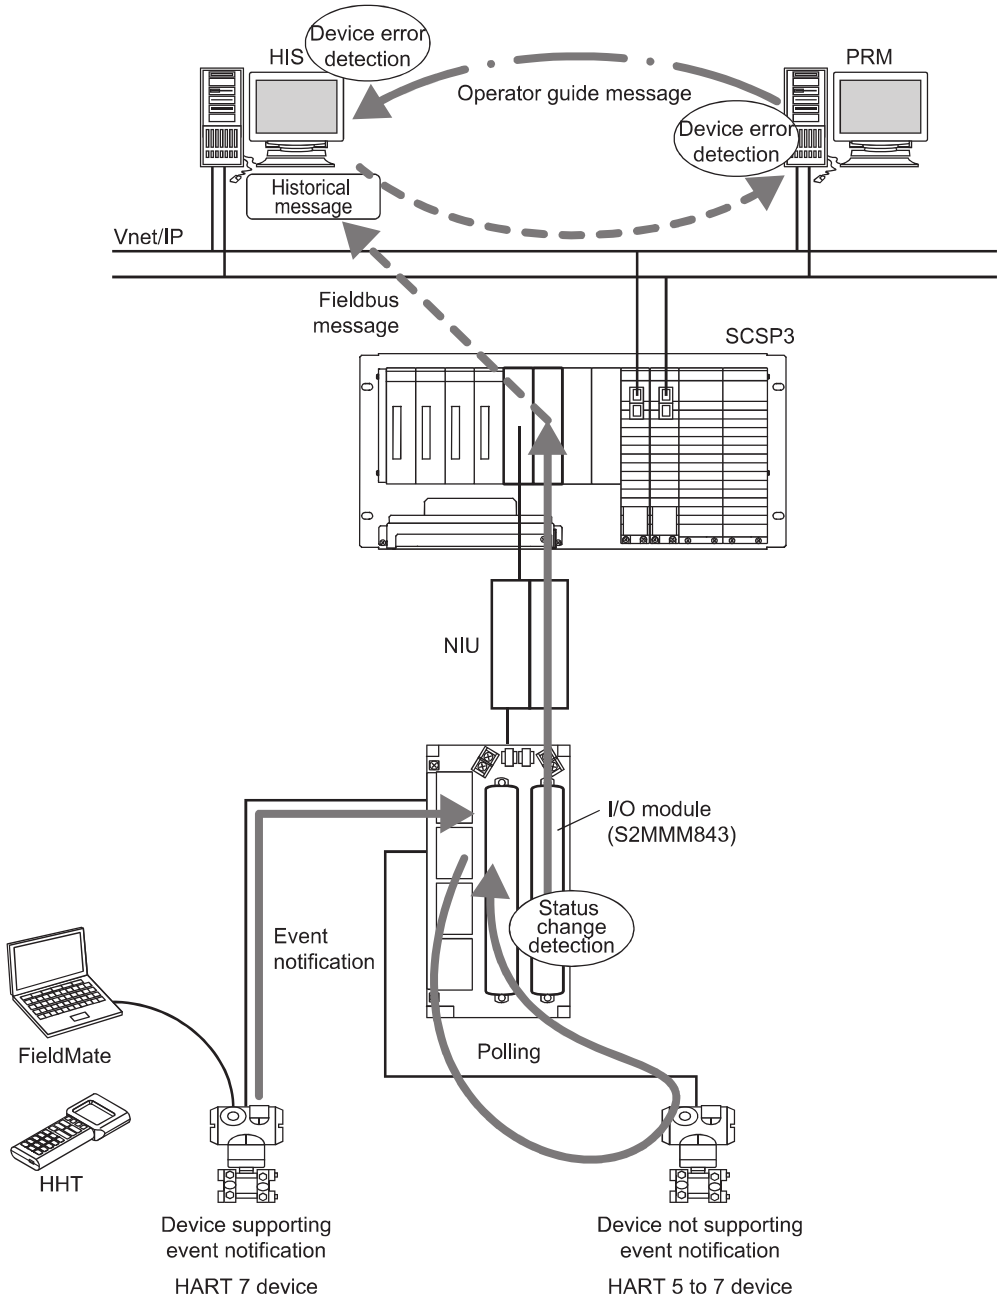

Figure A9.3.1-1 The concept of the notification of the status change in HART devices.

Device status change detection function

Analog digital I/O modules detect the status change in HART devices. The function is targeted for the signal category is AI or AO, and the channel with a signal type of current input (HART communication) or current output (HART communication).

The target models of the function are wired HART 5 to 7 devices.

There are two types of supported methods for transferring the status change:

- Event method: Receives events from HART 7 device.
- Polling method: Reads detailed information from HART devices at regular intervals and detects status change.

TIP

The I/O module identifies the target device and dynamically selects the transfer method.

I/O modules send the status change information of HART devices to the SCS.

SEE ALSO

For more information about precautions for the transfer method of the status change in HART devices, refer to:

A9.3.2, “Precautions for the transfer method of the status change in HART devices” on page A9-9

Device status change notification function

The SCS notifies the status change of HART devices, which is sent from I/O modules, to HIS as a fieldbus message.

HIS manages the fieldbus message as historical data and equalizes it with PRM.

PRM analyzes the fieldbus message that is received from HIS and updates the HART device status.

To notify the operators of the detected HART device failures or errors, configure operator guide messages in PRM.

A9.3.2 Precautions for the transfer method of the status change in HART devices

The following are transfer methods for the status change of HART devices:

- Event method
- Polling method

This section describes the precaution for each method.

Event method

The event method involves receiving events from HART devices.

The target of the event method is HART 7 devices where event notification is enabled.
