General-Purpose Calculation Formula (FCS0101_LOAD)

```
Line Number   General-Purpose Calculation Formula
   001        * FCS CPU loading communications loading calculation
   002        * This CALCU reads the FCS CPU idle time from the common-switch system flag
   003        * area and calculates the FCS load in per cent.
   004        * This makes the CPU loading available for trending purposes as CPV.
   005        * It also reads the common switches for communications loading as CPV1.
   006        * For FFCS V, common switches are %SW8065 onwards, in place of %SW0065
   007        * Issued 27 April 2012

1 INTRODUCTION

1.1 PROJECT OVERVIEW

Crosswind, a Shell and Eneco joint venture, was awarded the tender to develop the offshore Hollandse Kust Noord (HKN) wind farm, located 18.5km off the coast of Netherlands near the town of Egmond aan Zee. The consortium plans to have HKN operational in 2023 with an installed capacity of 759MW generating at least 3.3TWh per year. This is sufficient renewable power to supply more than 1 million Dutch households with green electricity.

Offshore wind farms produce intermittent electricity and balancing these dips and peaks and integrating this electricity into the national energy system requires new technologies. For this reason, the offshore wind farm will include several new technologies that could be implemented at full-scale in the future. The new technologies being explored include a floating solar park, a short-duration battery storage as well as long-term storage via green hydrogen produced by water electrolysis and subsequently consumed in a fuel cell. The combination of these individual measures, herein referred to as the Base Load Power Hub (BLPH) will ensure a continuous power supply regardless of the wind situation.

1.1.1 Project Location

The Hollandse Kust Noord (HKN) wind farm is located 18.5km off the coast of the Netherlands near the town of Egmond aan Zee.

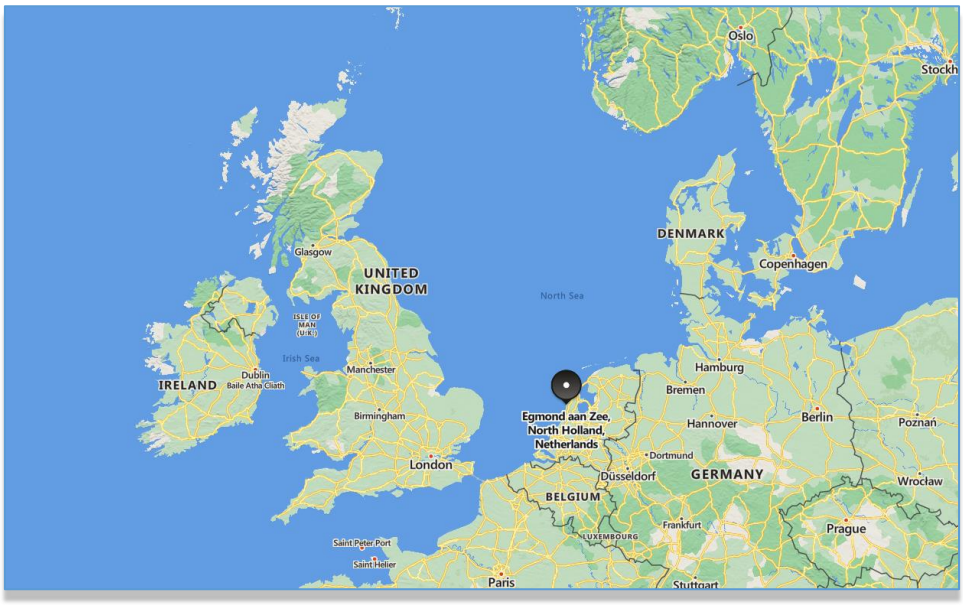

Figure 1 HOLLANDSE KUST NOORD WIND PARK Location Map

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

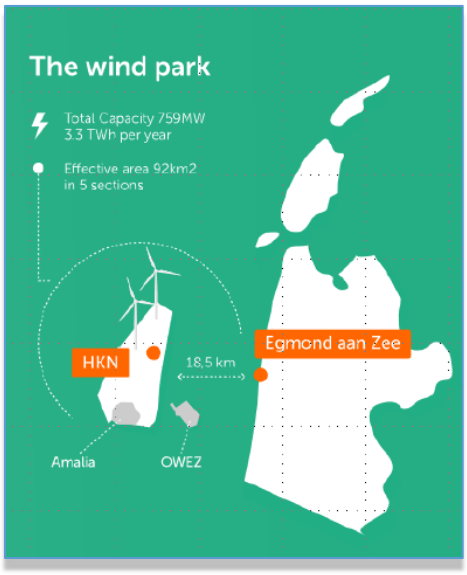

Figure 2 - Wind Park Details

The wind farm will consist of No. 69 x 11.5MW wind turbine generators each to be installed on a dedicated monopile structure. A 70th monopile located on coordinates E 590719.1, N 5841602.3 is reserved for installing the platform accommodating the BLPH. The monopile structure was designed and installed by Van Oord Offshore Wind (VooW) and therefore not part of the BLPH scope.

1.1.2 Project Concept

All components included in the BLPH will be integrated onshore on a topsides and installed in an offshore location within the boundaries of the HKN wind farm. At its simplest, the BLPH will store energy during periods of high electricity generation from renewable sources (a wind turbine generator and the floating solar PV farm) and release it during periods of low generation. In practice. It is expected that the energy stored will supplement generation from renewable sources to ensure that at least 1.0MW of power is exported to the electrical grid regardless of wind/solar availability.

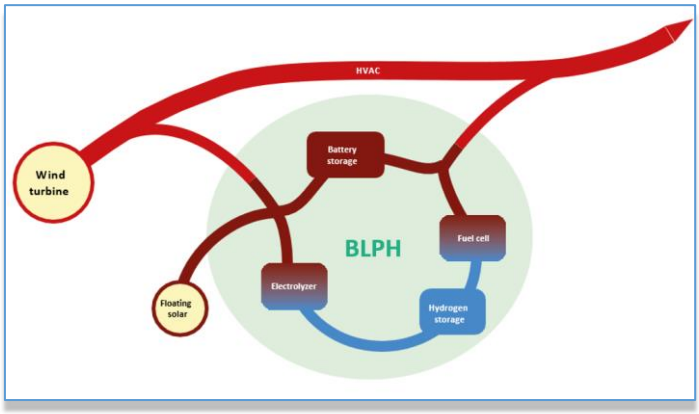

Figure 3 – BLPH Concept

Electricity in the BLPH will be stored in the form of electrons in a battery energy storage system (BESS) as well as converted into green hydrogen via water electrolysis. When the power output from the connecting wind turbine drops to below 1 MWe, the BLPH will return its stored energy to supplement the remaining power output. This will be by discharging the BESS, while stored hydrogen will be converted back into electricity using a fuel cell to extend the discharge duration.

The purpose of the BLPH s to function as a testbed for the integration of energy storage technologies with renewable generation. It is expected that equipment installed on the BLPH will operate as Normally Unmanned Installation for at least two (2) years with no or minimal maintenance and it will have its own independent control room with the ability to communicate with Crosswind's control room.

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

2 DOCUMENT SCOPE

In order to compare the application logic prior to modification and the application logic after the modification, the applications can be printed out with self-documentation. The consistency between the contents displayed on the windows and the contents in the printouts can also be confirmed.

Self-documentation is printouts the contents defined on the various builders and the tuning parameters to a document as archived materials.

3 LOGIC DIAGRAM PRINT OUT SIS AND FGS

The self-documentation function is independent of SCS Manager and each builder; it is thus possible to double-check that the applications have been created as intended.

Self-documentation prints out the source files of the work database in an SCS project.

3.1 SIS CONTROLLER SCS0110 LOGIC PRINT OUT

Refer Attachment-1 SCS0110 Controller Logic Print Out

3.2 FGS CONTROLLER SCS0120 LOGIC PRINT OUT

Refer Attachment-2 FGS Controller SCS0120 Logic Print Out

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

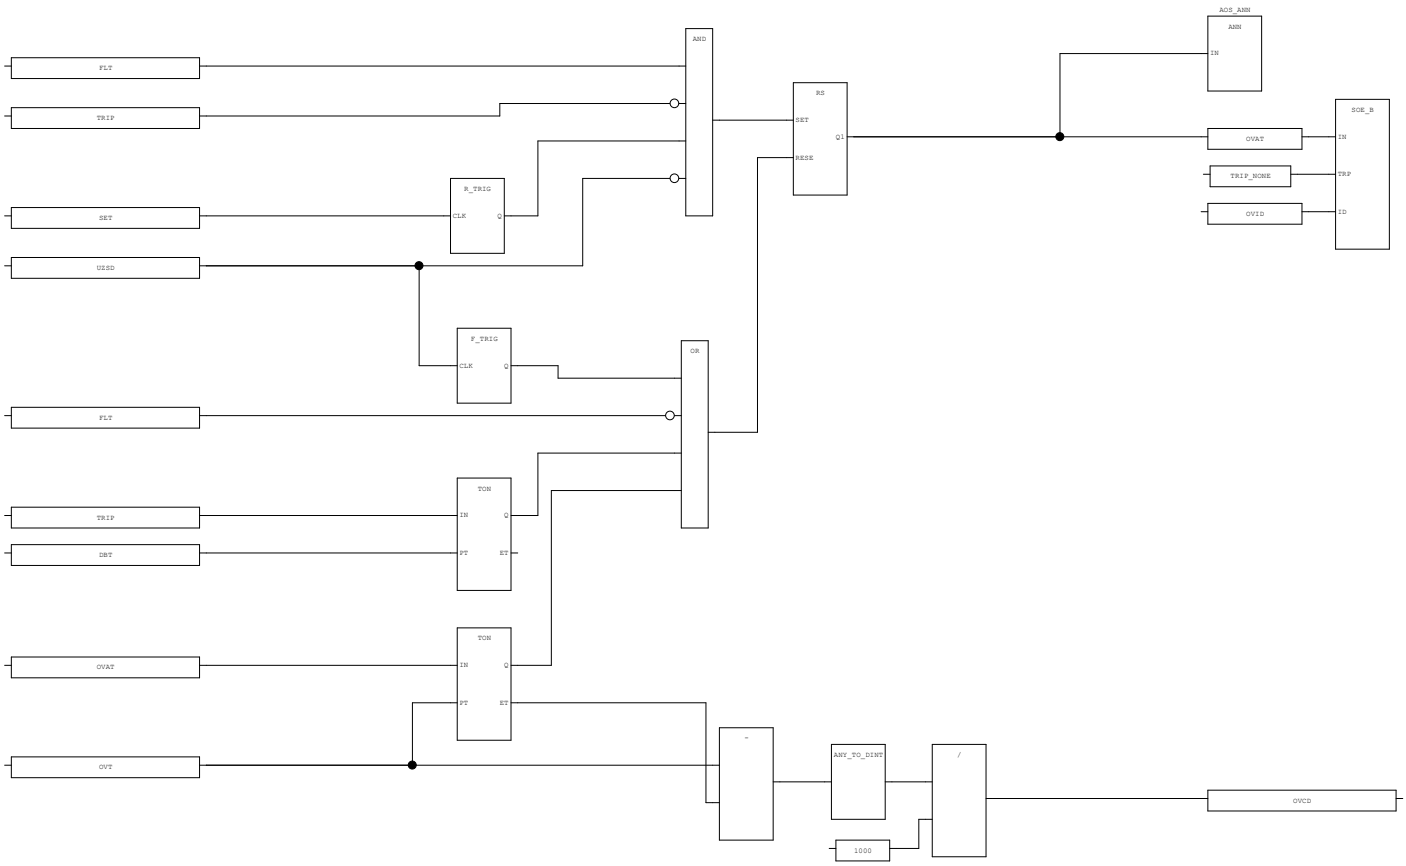
3.31. SPARE_POU_01 (* SPARE POU *)

3.32. SPARE_POU_02 (* SPARE POU *)

3.33. AOS (* IPS Override function *)

1.0.0

YOKOGAWA



TYPICAL : AOS (User Defined Function Block)

DESCRIPTION : This FB is used for the Automatic Operational Override. The AOS function block has the following main functions:
-Manage the Automatic operational override request.
-Reset the Automatic operational override when the override time is elapsed.
-Reset the Automatic operational override when the process value has reached above the Low set point for at least a predefined time (process settling time) within the allowed operational override time.
-Reset the Automatic operational override when the transmitter is faulty.
-Reset the Automatic operational override when the UZ group trips.

The Automatic operational override timer is activated by a UZ-group reset. The operational override will be activated on a rising edge of the reset signal if the following conditions are met:
-if the input typical is in Low Low alarm;
-and if there is no transmitter fault.
-and if UZ group tripped.

The operational override will be active as long as the operational override time is not elapsed. The operational override will be reset if:
-if the operational override time is elapsed;
-or if the process value has reached above the Low Low set point for at least a predefined time (process settling time) within the allowed operational override time,
-or if the transmitter is faulty.

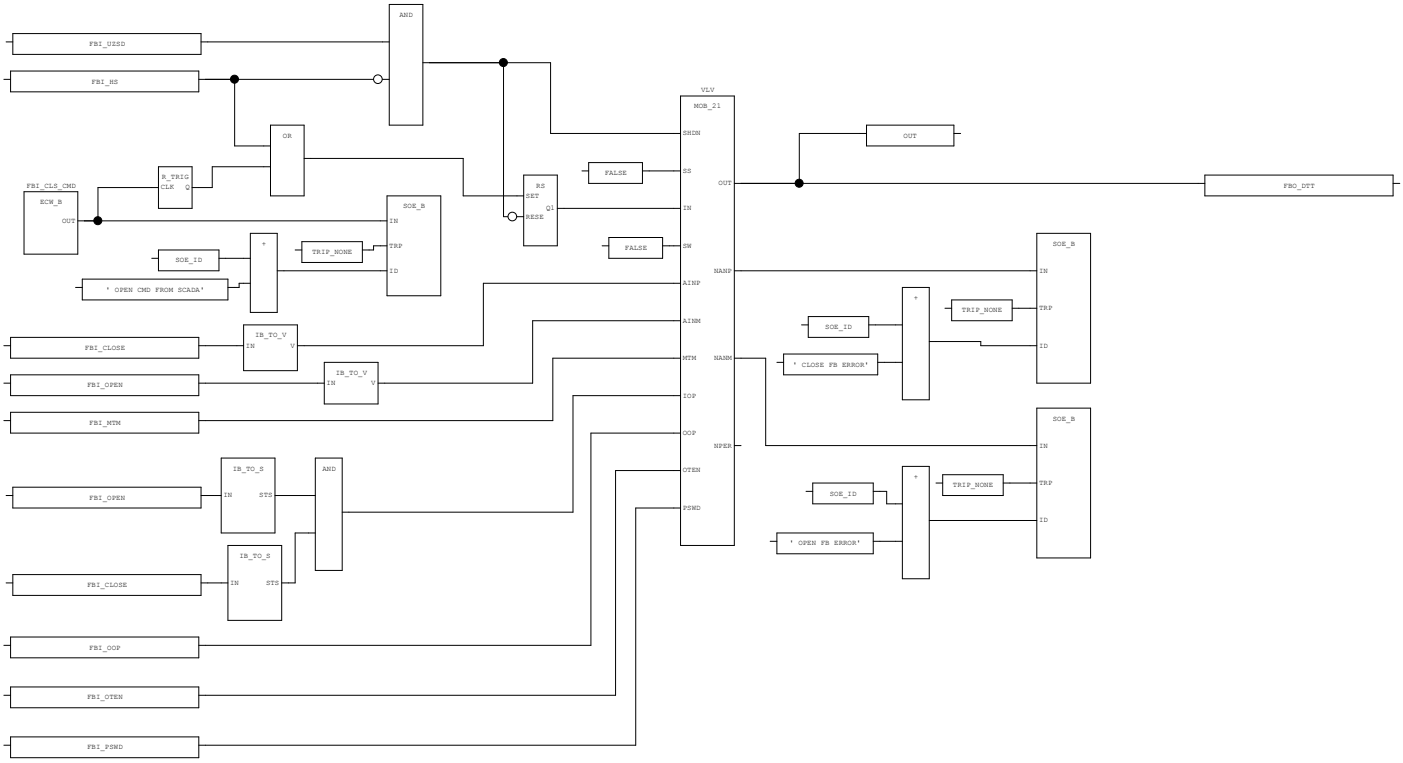
3.34. BDV (* Blowdown Valve with Limit switches *)



1.0.0

YOKOGAWA

TYPICAL : BDV(User Defined Function Block)

DESCRIPTION : Blowdown valve with limit switch feedback.
Typical to handle:
- Blowdown valve with limit switch input.
- Blowdown valve with Field Handswitch to initiate blowdown.
- Manual operation prohibited. Upon UZGRP reset,valve shall be closed manually ans returns to AUTO mode.

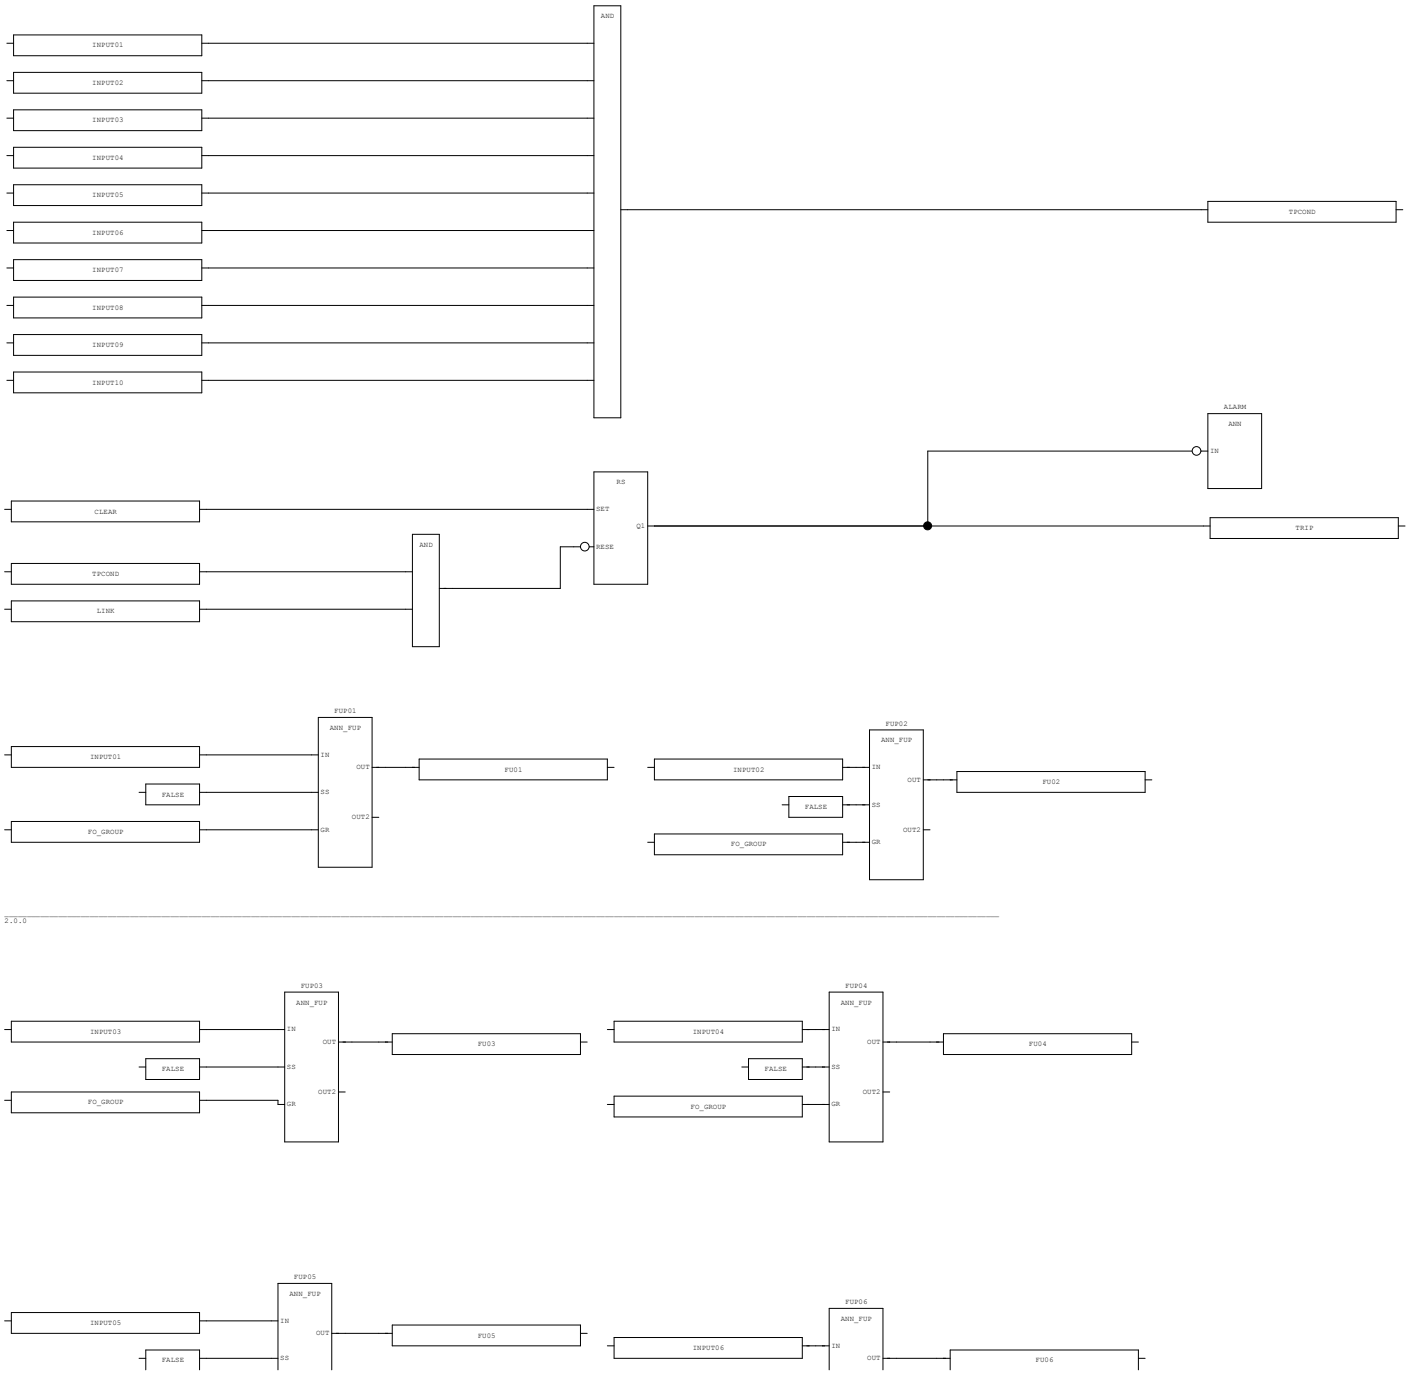
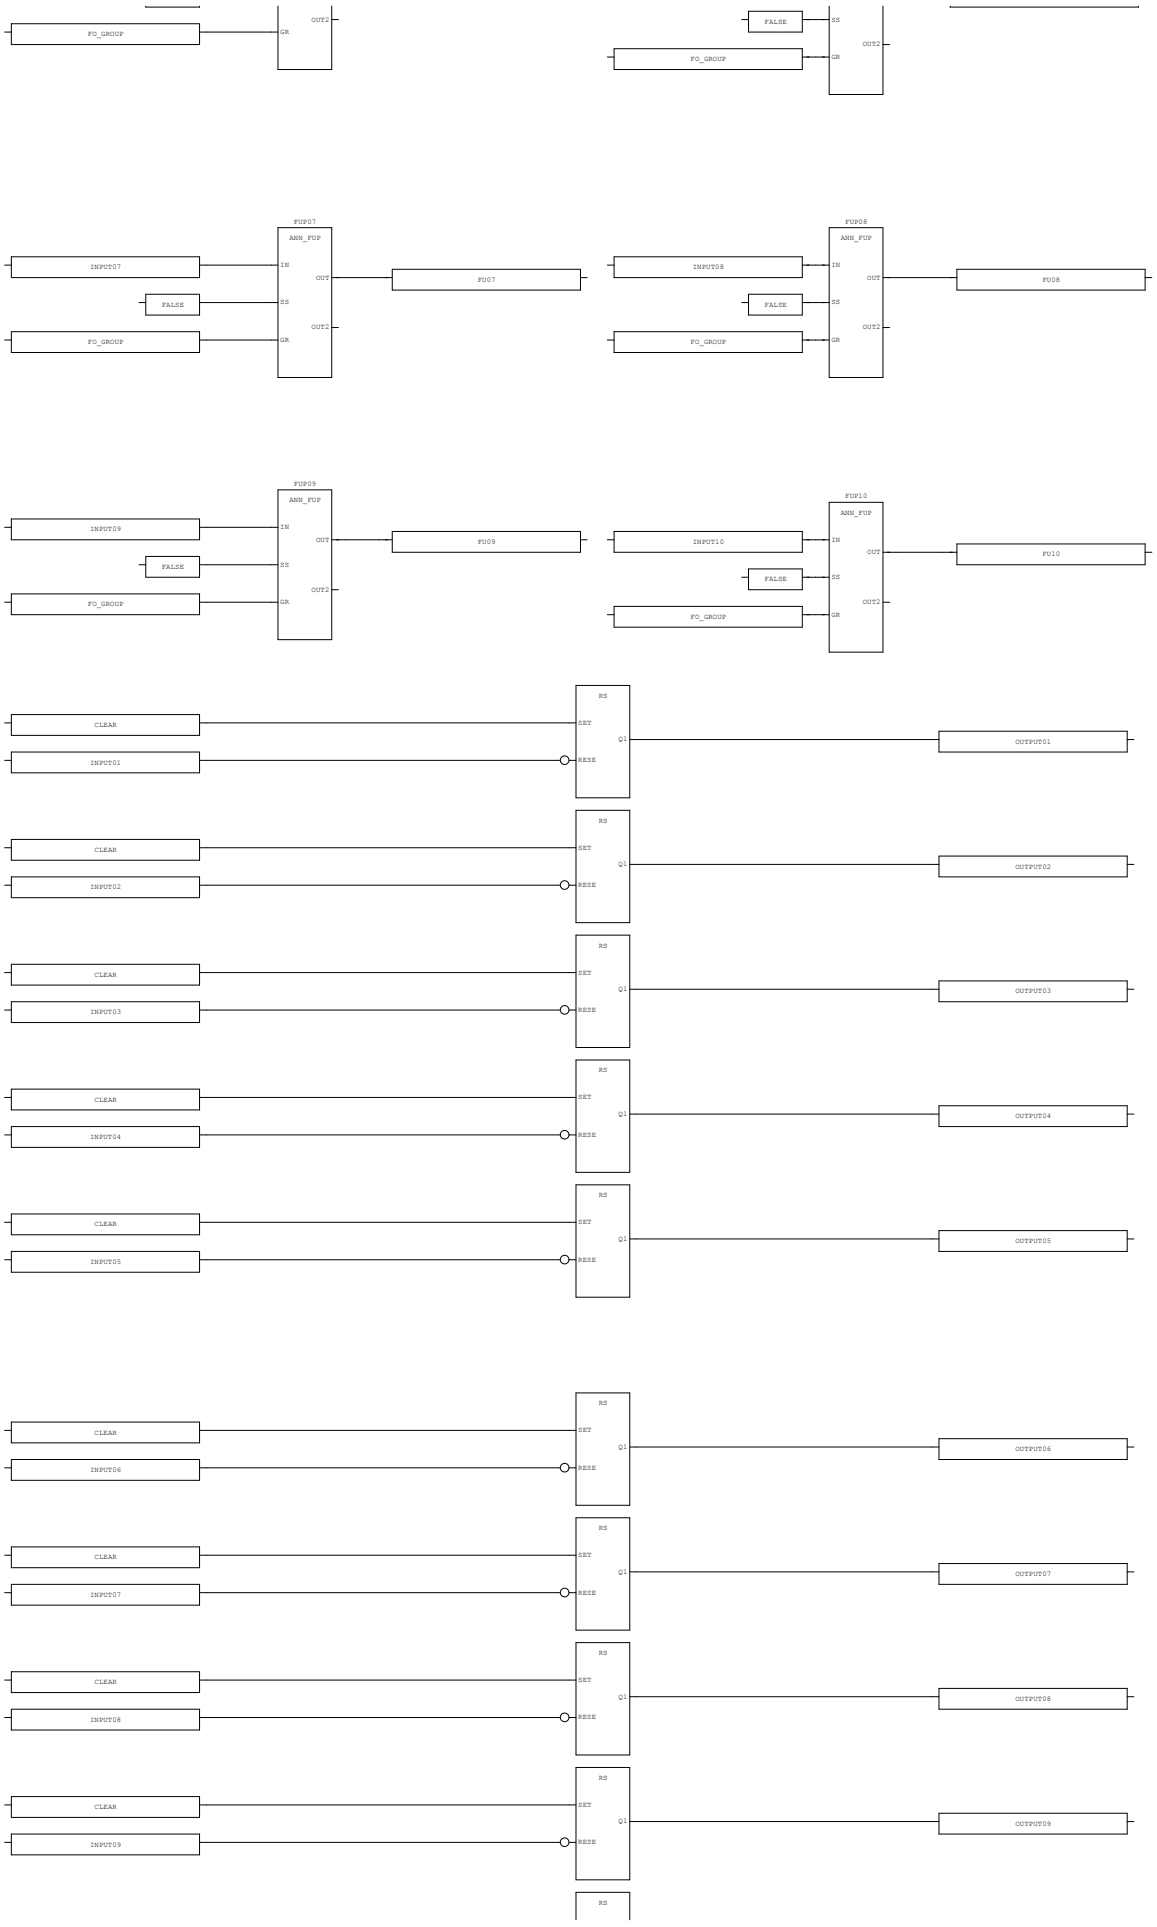
3.41. UZGRP (* IPS UZ group with 10 inputs *)



1.0.0

YOKOGAWA

TYPICAL : UZGRP (User Defined Function Block)



DESCRIPTION : This FB is used for the processing trip logic.
The UZGRP function block has the following main functions:
- Trip the UZ group if any of the input causes are in tripped state.
- Initiate a first out alarm.
- Latch the UZ trip until the causes have returned to normal state & no reset is activated.

1 INTRODUCTION

1.1 PROJECT OVERVIEW

Crosswind, a Shell and Eneco joint venture, was awarded the tender to develop the offshore Hollandse Kust Noord (HKN) wind farm, located 18.5km off the coast of Netherlands near the town of Egmond aan Zee. The consortium plans to have HKN operational in 2023 with an installed capacity of 759MW generating at least 3.3TWh per year. This is sufficient renewable power to supply more than 1 million Dutch households with green electricity.

Offshore wind farms produce intermittent electricity and balancing these dips and peaks and integrating this electricity into the national energy system requires new technologies. For this reason, the offshore wind farm will include several new technologies that could be implemented at full-scale in the future. The new technologies being explored include a floating solar park, a short-duration battery storage as well as long-term storage via green hydrogen produced by water electrolysis and subsequently consumed in a fuel cell. The combination of these individual measures, herein referred to as the Base Load Power Hub (BLPH) will ensure a continuous power supply regardless of the wind situation.

1.1.1 Project Location

The Hollandse Kust Noord (HKN) wind farm is located 18.5km off the coast of the Netherlands near the town of Egmond aan Zee.

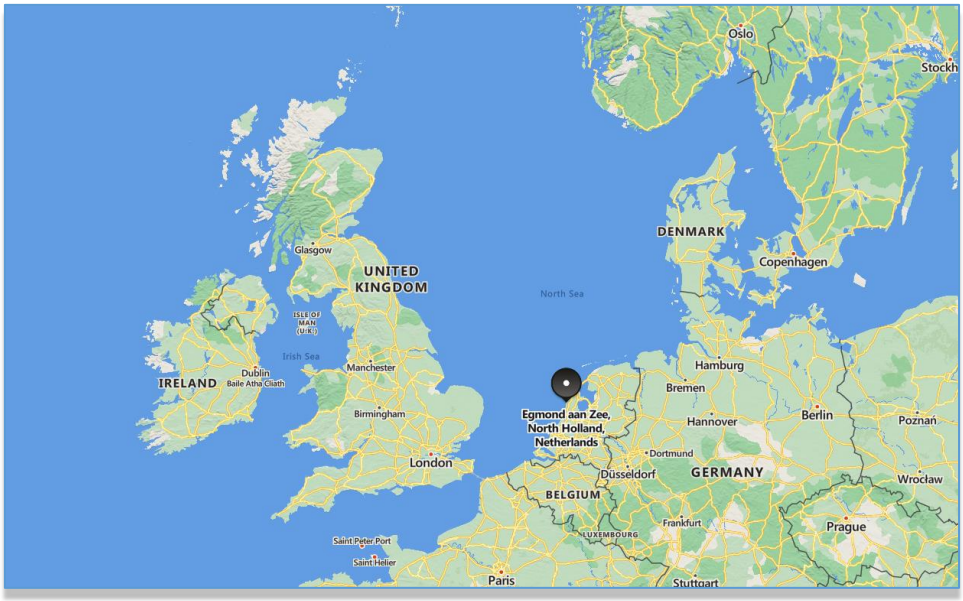

Figure 1 HOLLANDSE KUST NOORD WIND PARK Location Map

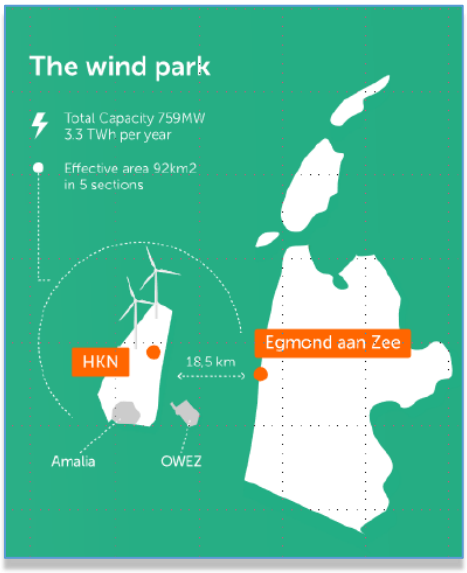

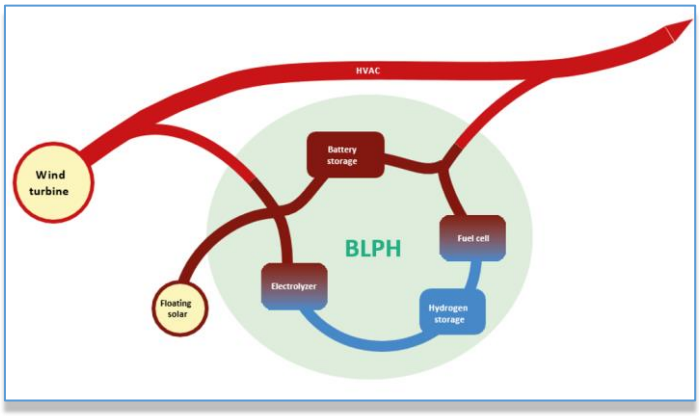

Figure 2 - Wind Park Details

The wind farm will consist of No. 69 x 11.5MW wind turbine generators each to be installed on a dedicated monopile structure. A 70th monopile located on coordinates E 590719.1, N 5841602.3 is reserved for installing the platform accommodating the BLPH. The monopile structure was designed and installed by Van Oord Offshore Wind (VooW) and therefore not part of the BLPH scope.

1.1.2 Project Concept

All components included in the BLPH will be integrated onshore on a topsides and installed in an offshore location within the boundaries of the HKN wind farm. At its simplest, the BLPH will store energy during periods of high electricity generation from renewable sources (a wind turbine generator and the floating solar PV farm) and release it during periods of low generation. In practice. It is expected that the energy stored will supplement generation from renewable sources to ensure that at least 1.0MW of power is exported to the electrical grid regardless of wind/solar availability.

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

Figure 3 – BLPH Concept

Electricity in the BLPH will be stored in the form of electrons in a battery energy storage system (BESS) as well as converted into green hydrogen via water electrolysis. When the power output from the connecting wind turbine drops to below 1 MWe, the BLPH will return its stored energy to supplement the remaining power output. This will be by discharging the BESS, while stored hydrogen will be converted back into electricity using a fuel cell to extend the discharge duration.

The purpose of the BLPH s to function as a testbed for the integration of energy storage technologies with renewable generation. It is expected that equipment installed on the BLPH will operate as Normally Unmanned Installation for at least two (2) years with no or minimal maintenance and it will have its own independent control room with the ability to communicate with Crosswind's control room.

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

2 DOCUMENT SCOPE

The purpose of this document is to provide a general description of the control logic implemented in the Energy Management and Control System (EMCS) of the CROSSWIND BLPH project.

3 SOFTWARE ARCHITECTURE

The EMCS control logic is written using the set of language of IEC 61131-3 standard and run in SEL RTAC 3555 industrial computers (PLC).

The basic concept of the EMCS is that the system is in one of the modes defined in the

FDS (1724000594-IN-SP-00019) :

- IDLE
- IMPORT CHARGING
- IMPORT NOT ABLE TO CHARGE
- HOT STANDBY
- EXPORT
- COLD STANDBY
- EMERGENCY
- POWER OUT
- RESEARCH
- MAINTENANCE
- NONE

When a mode is selected, the EMCS execute a set of routines to perform the actions (start and stop packages, impose setpoint, open or close CBs, …) required by the execution logic defined for the mode.

The Figure 4 shows a diagram representing the software components involved in the mode selection:

- EMCS Mode Processor: responsible for evaluating the precondition and to select the current mode. Internally it contains two sub components: the Mode Selector and the Mode Activator.
- Real-Time Data Cache: responsible to store the snapshot of the field variables
- Protocol Drivers: a set of clients implementing a specific protocol (MODBUS, IEC 61850, OPC-UA) responsible to collects the data from the field devices
- Field Devices: are an abstraction of the field devices
- Mode[i]: software components responsible to execute the control logic of a specific mode.

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

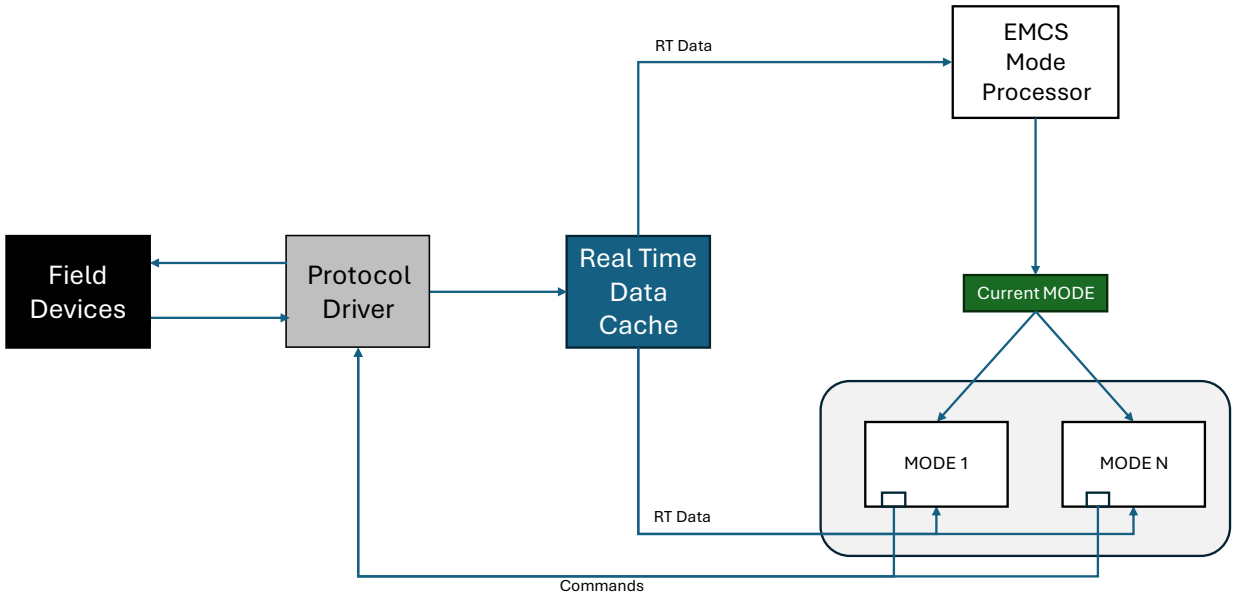

Figure 4 – EMCS Mode Selection

Each mode is implemented as an independent Function Block with its internal state machine. The picture Figure 5 shows the status of a mode and the process involved in the transition between one mode and another. The picture shows as an example the Research and Maintenance mode, but the concept can be extended to all modes.

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

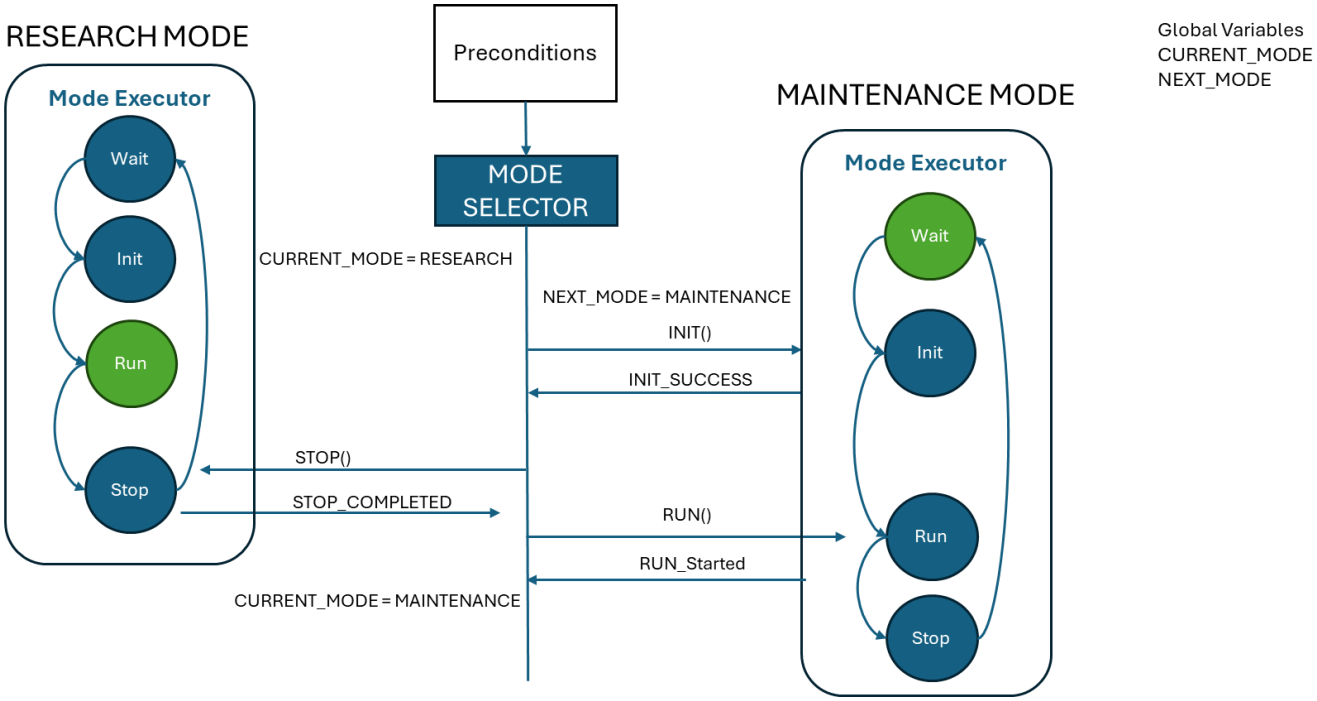

Figure 5 – Mode state machine and transitions

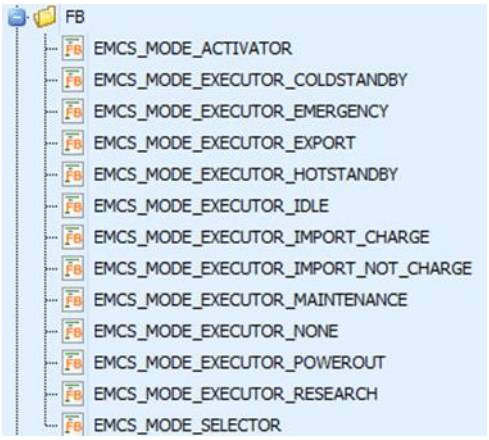
In the above example, the Mode Selector block continuously evaluates the preconditions received as input to establish if a MODE transition is required. The Mode Selector uses two global variables:

- CURRENT_MODE: reports on what is the current executing MODE
- NEXT_MODE: reports on what the next MODE to execute should be based on the status of the preconditions.

In the example, the precondition regarding the EMCS Manual-Automatic Mode is changing from Research to Maintenance. This happens when the SCADA operator switches manually the AUTO-MANUAL mode selector from Research to Maintenance MODE.



Whenever the NEXT_MODE differs from the CURRENT_MODE, a transition is initiated. During the transition, first it is evaluated if the transition to the NEXT MODE can be performed.

In the example, the Mode Selector calls the *init* function of the Maintenance Mode Executor to check if the transition can be done. If the *init* function returns success, the Mode Executor calls the stop function to the Research Mode executor and then calls the *run* function to the Maintenance Mode Executor. After the transition both CURRENT_MODE and NEXT_MODE variables report Maintenance MODE.

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

CROSSWIND	HOLLANDSE KUST NOORD WIND PARK Project Contract No. CW-I-WP4-2023-05	ROSETTI MARINO
Document Title:	Logic Diagram Print Out EMCS	Sheet 15 of 92 Date: 30/07/2025 Rev: 01

From the RTAC project point of view, each mode logic is contained in a dedicated file.

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

4 SOFTWARE CODE

In this chapter the code regarding the EMCS MODEs transition and execution is printed out.

4.1 EMCS MAIN VARIABLES

```
VAR_GLOBAL
      IsMaster : BOOL;
